The annual meeting of the Motor Union, recently held, has revealed a surprising growth in membership during the past year. Since the previous meeting the affiliation of twenty-four clubs increased the number of members by 3,524, and the addition of over 1,000 individual members had made a grand total of over 14,800 in the Union. While the Royal Automobile Club—the new distinctive title conferred by King Edward on the A. C. G. B. I.—looks after the social and competitive side of motoring, the Union safeguards the legal interests of the youthful industry. Applications for the imposition of speed limits in towns are opposed when this course is desirable, and the well supported arguments offered by the Union have in many cases resulted in the rejection of the application. Appeals against vindictive sentences on motorists are undertaken whenever such proceedings are likely to benefit motorists in general. Further, in view of the importance to the motor industry of a suitable and adequate supply of fuel, a competent committee of the Union has been pursuing work on this question for several months and the report may be expected to contain much valuable information.

The Motor Union Insurance Co. is now firmly established, and the benefits resulting to members have exceeded the original expectations. A further innovation which is expected to be productive of useful results is the provision of special badges which are issued to members for attachment to the dashboard or bonnet of their cars. Members of the Union will by this means be easily identified, and as the badges remain the property of the Union, the committee can demand their return in cases of inconsiderate driving. With the big membership and a balance in hand of over \$8,000, much good work will doubtless be performed during the coming year.

Makers Will Limit the Shows.

The continuous succession of provincial shows and exhibitions, at which the enterprising manufacturer feels compelled to exhibit, seems likely to die out in future years. From the Olympia show last November till now show chassis and tired attendants have been traveling round the country looking for business which—often enough—was not to be booked. Conditions of business in

the motor industry have undergone a radical change in the past few years, and the greater proportion of business with private customers is now in the hands of local agents who do not need a show to come into contact with their customers—most of whom, indeed, they will know in person. A bright individual over here has just grasped this fact, and the general chorus of approval which has greeted his proposal to boycott provincial shows—with, perhaps, an exception in the case of two or three large cities—argues that the stand attendants will have more leisure time next year. The objection, of course, hardly applies to London shows, and the Agricultural Hall exhibition, which opens its doors to-morrow, can generally be relied upon to bring out some novelties in the car line. With this show the end of the winter session may be said to be marked, and the season of road contests straightway commences.

No American Cars in Isle of Man Events.

The Isle of Man events are this year to be held in May, commencing the Manx holiday season. Quite an interesting week's racing is provided, commencing with the Tourist Trophy race on Tuesday, May 28. This will be run off on the same course as last year and some thirty cars have already been entered, while several others are expected to rank before the list closes on May 1. No American representative is to be found among the competitors this year.

On the following day a Tourist Trophy race for motorcycles will be run off, and the Heavy Touring car race—with its fuel limitation of one gallon of gasoline for every sixteen miles of road—on the Thursday. The five miles race for the Graphic Cup on Friday will finish an interesting series of events.

The long-distance reliability trials of the Scottish and Irish Automobile Clubs always attract many entries. These popular events will be held, the latter in May and the former at the end of June. The total distance in each case is about 650 miles, and the cars are under continuous official observation till the finish of the trials. Observers of the experienced sort are employed.

M. MICHELIN INTERVIEWED "AT HOME."

PARIS, April 5.—Home again from his visit to the United States, Edouard Michelin, the tire king, has given his opinion of things in the land of the almighty dollar. Ground for the new factory is already bought, for it is not his intention to make use of an existing building, and work has already begun. A group of French engineers and foremen will be sent over, but American workmen will be employed. The American workmen are active, clever, good workers, and they do not bother with politics. "When the new factory is completed," said Michelin, "we shall avoid the 35 per cent. custom duty and pay our men the American scale for the most skilled workers.

"French workmen who are dissatisfied with home conditions should go out to the United States; the railways especially are hard pressed for men, and the most unskilled mechanic can earn \$4 a day."

Replying to a question on the American invasion of Europe, M. Michelin said he was convinced that there was no need to be afraid of it. "In the United States automobile production doubles from year to year, and still the manufacturers are unable to satisfy the home demand."

"We have been exceedingly well received in the United States; indeed the spirit of the American is such that every stranger setting foot in the country is almost immediately considered a citizen. Already we are classed over there as American producers, and no one looks upon us as invaders. Automobilists are charmed that we have come to give them good tires for their bad roads and in a short time you will see that 'Michelin boit l'Amerique.'"

WITH THE MOTOR BOATS AT MONACO

MONTE CARLO, April 5.—When motor boats were giving displays of unseaworthiness, and minor meetings were laughable failures, self-ordained prophets were predicting the collapse of the great annual Monaco auto boat meeting. A few months ago a rather diminutive entry list appeared to corroborate their dismal forecast, but to-day they have been effectively silenced. Seventy-five handsome craft bearing engines made by the most famous motor builders of France, Italy, Germany, England and Switzerland, are united in the gay open-air exhibition

are absent from the meeting, but the proportion of absentees is much lower than in previous exhibitions. Numerically there is an increase of 40 per cent. over last year's motor boat meeting. In engine construction there is little that is new, but in the designing of hulls enormous progress has been made. Not only will the racers be faster than those of last year, but they are more fitted for speedy work in a seaway than ever before. Among the 26-footers France has *La Rapiere II*, fitted with a new Panhard & Levassor motor; the *Anadyomene*, with a powerful

ART AND NATURE UNITE TO FORM AN IDEAL EXHIBITION GROUND FOR THE ANNUAL MONACO MEET.

preparatory to being launched in the blue waters of the Mediterranean for their official speed tests.

There is the usual army of sporting enthusiasts, boat builders, engineers and automobilists, a big proportion of the Paris motor world and the élite of the floating population which annually makes Monaco its winter home. For the first time the Prince of Monaco was unable to open the meeting officially, but sent his regrets, and delegated the Governor of the principality to preside over the brilliant ceremony.

The seventy-five boats are divided into four distinct classes: cruisers, racers, vedettes, and hydroplanes. The cruisers are subdivided into four classes with limited length over all and restricted cylinder area; racers are classified up to 26 feet in length and above this length; vedettes are seagoing boats intended for service in the navy or for work in estuaries and river mouths, and hydroplanes are left free from all restrictions either as regards size or engine. A few which signified their intention of competing

Delahaye engine, and *La Mouvette*, engined by Mutel. Italy has *Fiat XV, Itala*, with a 135-horsepower Itala motor, Baron de Cater's *Seasick*, with an Itala motor, hull and engine, being of last year's construction.

Public interest centers in the racers of more than 26 feet length, for the greatest speed is expected from these powerful boats. England again challenges the supremacy of the Latin races on water with a couple of Daimlers owned by Lord Howard de Walden and the *Flying Fish* belonging to Lionel de Rothschild and engined by the Wolseley Company. *Jeanette* is the solitary Italian representant. Germany has *Mercedes D. L.* and France the *Panhard-Tellier* with a Panhard motor, and *New Treffe*, owned by Thurbon and engined by Brasier. *Daimler II* has three six-cylinder 90-horsepower motors, each driving a separate propeller. She is strongly constructed of steel and is looked upon as a particularly fast craft for open sea work. The *Panhard-Tellier*, which should prove the fastest of the fleet in calm water, has two

THE ALL-CONQUERING PANHARD-TELLIER.

Panhard motors used in the Grand Prix cars of last year.

For the first time hydroplanes figure officially in the races, and although only three in number, will doubtless excite interest far in proportion of their numerical value. Comte de Lambert's craft is of particular interest from the fact that it is propelled by a 70-horsepower Antoinette engine driving an aerial propeller. There is practically no skin friction and on calm water the curious craft should be capable of enormous speed. The *Obus-Nautilus* is of quite a different type, consisting of a couple of floats united by a metal frame, one of the floats carrying the engine, the other bearing the pilot, gasoline tank and steering gear. The *Motogodille-Glisseur*, presents further distinctive features, its motive power being entirely contained at the rear, and the propeller shaft mounted on a kind of universal joint allowing the screw to be lowered into the water or withdrawn at will. The appliance is largely used in France for small boats, but this is the first time it has been mounted on a hydroplane.

Although there is less public interest in the vedette section, these boats will be examined with more curiosity by seamen than all the fast racers and luxurious cruisers, for they are the utilitarian application of the internal combustion engine to marine work. The French Minister of Marine, M. Thomson, is personally interesting himself in these boats, and has offered a special prize. They are all powerful seagoing craft, few of them fast, but all capable of putting out in half a gale of wind. Cruisers have less that calls for attention than the boats in the other classes. Engines are more protected; hulls are more seaworthy than was the case a few years ago, but there have been no radical changes.

Fast Time at Monaco Races.

Cable reports from Monte Carlo announce a number of races postponed on account of bad weather, but very fast time in those

STERN VIEW OF THREE-SCREW DAIMLER CRAFT.;

that were run. In the Championship of the Sea, the most important event of the meet, seventeen boats started. *Panhard-Tellier* got ahead from the start and maintained a distinct lead throughout the 200 kilometers, finishing in 3:33:4, or at an average of 34.77 miles an hour, beating the record by 1 hour 17 minutes. *All' Erta*, with Fiat engines, was second in 4:46:27; *Ulysee*, with Mors engines, was third; *Flying Fish*, with Wolseley engines, fourth, and the *Adèle*, with Mors motor, was fifth. *Mercedes D. L.* was the only other boat to finish in the eight hours limit. In the 50-kilometer handicap for both cruisers and racers, the *Ressac* finished first, with *Roys d'Ys* second in the cruiser section; *Mercedes D. L.* was first in the racing class, with the British boat *Flying Fish* second, and Baron de Cater's *Seasick* third. In the mile and kilometer races for craft having completed any fifty kilometers event, *Panhard-Tellier* was the fastest, covering the standing mile in 2:9. *La Rapière*, also with a Panhard motor, was second in 2:25. *Flying Fish* took third prize. By this performance the *Panhard-Tellier* secured the Prince of Monaco's cup, valued at \$2,000, in addition to \$1,000 money prize.

The closing day of the Monaco meet witnessed two races of little interest, one being a 25-kilometer contest for all boats and the other a handicap for the same distance. Owing to a rising sea only the British racer *Flying Fish*, owned by Lionel de Rothschild, was able to finish. The weather during the meet has not

SIX-CYLINDER HOTCHKISS FINISHING LONG WINTER TRIP.

been favorable and the boats have been unable to show all the speed of which they are capable. The *Panhard-Tellier* has been the victor of the meeting, showing herself fastest in both rough and smooth water. Hydroplanes have been the novelty, Comte de Lambert's aerial propeller craft attracting most attention.

HOTCHKISS MAKES 6,200-MILE TOUR.

PARIS, April 6.—Having covered 6,200 miles over winter roads, the six-cylinder Hotchkiss, piloted by M. Van Marcke, arrived again at the Place de la Concorde, in front of the Automobile Club, after an absence of fifty-eight days. The test was undertaken to prove the reliability of the car under the worst climatic conditions and over the most difficult roads of France. It must not be supposed that the run was a pleasure trip over billiard-table roads, for the car negotiated the Pyrenees, the Alps, the Vosges mountains, the hilly central district of Auvergne, and the wild roads of Brittany and Finistere. The car was equipped with a side-entrance double-phaeton body and all touring requisites, and carried four passengers. Michelin patent dismountable rims were employed and gave every satisfaction throughout the long test. The illustration shows the arrival of the car on the Place de la Concorde, where the tourists received a hearty welcome from friends and interested persons. Madame Van Marcke, on the right of the car, does not appear to be at all displeased at the return of her husband. THE AUTOMOBILE Paris photographer is seen standing on the right.

A. L. A. M. TAKES UP TIRE STANDARDIZATION

FOLLOWING up the good work that has been accomplished in other essentials, the Mechanical Branch of the Association of Licensed Automobile Manufacturers is now about to turn its attention to the important matter of standardizing tire sizes and weights. As an outline of what is to be done the appended information has been issued and will be found interesting reading:

Tires and their standardization, a problem that has confronted the automobile industry from its inception, is to be the next big work of the Mechanical Branch of the Association of Licensed Automobile Manufacturers. The success of the association's screw standard, its standardized spark plug, its various experiments in metals and oils, and its many educational engine tests will be followed by a series of tire tests, and adoption of standards which will be of material advantage to all motorists and manufacturers.

The tire situation is one that for a long time has not only bothered automobile manufacturers and users, but the tire makers themselves. The peculiar position subjected to tire selection and the number of people through which it had to pass rendered it very confusing. The tire maker, rim maker, automobile manufacturer and consumer. The lack of standard methods as to the quality and size resulted in the tire makers becoming more or less uncertain of the conditions to be imposed upon them by the users.

Under the direction of the Tire Committee, the Mechanical Branch's experts have made several tests in the quality and size of tires to determine what specifications will be adopted and standards recommended which will call for uniformity throughout.

Comparative Test for Quality.

Tests show that the part of the tire nearest the ground and what is known as tread rubber, to give the best results should be of compound rubber, as pure rubber would not stand the continuous friction caused by coming in contact with the road surface. Near the center of the tire comes the "breaker strip," made up of two or three layers of canvas separating the tread from the next layer of rubber or "cushion stock." The "cushion stock" is usually of the highest class rubber, being only slightly compounded; the next layer towards the center is a five or six-ply fabric, frictioned inside and out. The degree of compounding can be obtained by the specific gravity of the rubber, it being known that the specific gravity of pure rubber is between .950 and .980. The ash, after burning the rubber at a low degree of heat, represents the degree of compounding, independent of the sulphur used for vulcanization. To determine the strength, a strip of rubber is cut from each of the different layers of qualities in the tire, 1-4 inch wide and 1-8 inch thick. One end is gripped and weights are then added to the other end until the strip breaks. A Para rubber shows high strength, and the cheap rubber low strength. In determining the elasticity a similar strip is cut from the tires, 1-4 inch by 1-8 inch, and a measured length of 10 centimeters is taken. The strip is then stretched between nails on a board until the 10 centimeters length becomes 30 centimeters. It is kept in this position for 24 hours, then released, and 10 minutes after release the permanent set

taken. A good rubber has small permanent set; a poor and a cheap rubber has much permanent set.

Relative Size of Tires.

Considerable discussion has been given to the relative merits of different size tires on front and rear wheels. The size of tires, of course, depends on the weight of a car and its gearing. Many manufacturers have found it to advantage to use a smaller diameter tire on the front wheels than on the rear, and careful investigation seems to prove this to be wise. First, it is much easier to steer, it having a smaller friction area on the ground surface, this makes the wear on the tire, on the whole, considerably less, with chances for punctures decreased. It has less weight in itself and is better proportioned to the weight of the car, which is, of course, heavier in the rear. For high-powered cars, that is, cars required to attain a speed of from 40 to 60 miles an hour, the smaller the diameter of the front tire, the less the danger in case of blow-out or puncture. S. F. Edge, a noted English driver, has made several tests to determine the relative shock caused by punctures, of different size front tires, with the result that with a 3- or 3½-in. tire, a car going 50 miles an hour would be thrown not over 6 or 8 feet, while with an explosion of a 5-in. tire, it would be thrown from 30 to 40 feet. Economy and safety call for a smaller diameter front tire. Many do not think it an economy to carry two size tires, but in the long run it will be found more advantageous. For racing purposes a French driver will not use over a 90-mm. tire on the front wheels.

Adoption of Universal Size.

One of the first recommendations of the Tire Committee of the Mechanical Branch was the elimination of so many sizes of tires, that is, the wheel sizes. Up to the time the Mechanical Branch took hold of this matter, there were 23 sizes of tires in the market, many of which were incapable of doing the maximum amount of work required, owing to their being of wrong proportion, not only for the weight of the car, but the area of the ground surface. Experiments by the Branch have resulted in a reduction of this number and the adoption of 11 sizes:

28x3	30x3	30x3½	32x3½	32x4
34x3½	34x4	34x4½	36x4	36x4½
		36x5		

Uniformity in Rims and Felly.

A great difficulty that has confronted the automobile manufacturers is the various sizes of rims on the market, thus causing considerable rim-cutting to tires. Many of the rim-makers of single-piece rims had a uniform size diameter and depth of clinch, but not all. Through the efforts of the Branch, the rim-makers have all agreed to a standard size rim, to be inspected and passed by the tire-makers, who will guarantee any tire bearing the rim associations stamp.

Tests and experiments are being made for the standardization of quick detachable tires and demountable rims, results of which, when completed, will prove of considerable advantage to all.

STANDARD FORMULA FINALLY TO BE ADOPTED

AT last the figuring of horsepower has come in for attention, the Mechanical Branch of the Association of Licensed Automobile Manufacturers having taken up the question of establishing a standard formula at its meeting last week. The standards suggested are to consist of a brake test, in connection with a formula to be suggested by the Test Committee. Two units are to be used, the lower being the actual rating from the brake tests, as computed from an indicator at 1,000 feet per minute piston speed, and the higher number to be the maximum horsepower developed from superior workmanship or the results of a better type motor. For example, in a 20 to 24-horsepower motor, the 20 would be the actual horsepower at 1,000 feet per minute piston speed and the 24 the horsepower which would be developed when not under normal conditions.

A discussion of alcohol-acetylene as a fuel followed. The growing need of a substitute for gasoline was realized, but

whether alcohol-acetylene combination would supplant the present fuel supply is a problem yet unsolved. Thos. L. White, of Barker & White, exponents of the new fuel, gave a most interesting illustrated talk on the subject. Mr. White predicted that by September 1 alcohol could be obtained at a figure less than 20 cents per gallon, and that in certain places and in quantity carbide could be purchased for this purpose at one cent per pound.

A business meeting of the branch followed the regular session, and three new members were added to the Tire Committee, in order to assist in the furtherance of the standardization of tires which they have adopted. The new members are S. D. Waldon, Packard Motor Car Company; R. B. Jackson, Olds Motor Works; E. F. Russell, Locomobile Company of America. Owing to the amount of work which is being done by the Test Committee it was thought advisable to add another member to this committee, and J. G. Utz, of the Autocar Company, was named.

GRAND PRIX PREPARATIONS.

PARIS, April 6.—Apostles of the simple life will be delighted to hear that there will be camping facilities at the Grand Prix. Last year the same happy state existed on the Sarthe Circuit, but as the simple livers had to erect their own tents, after clearing the land of timber, cook their own food and roll their own beds, most of them preferred the voluptuousness of an old-fashioned

PLAN OF THE GRAND PRIX GRAND STAND NEAR DIEPPE.

feather bed and a diminutive bowl for morning ablutions. This year conditions will be changed; the Automobile Club of France having decided to rent a large plot of land close to the grandstands, cause a contractor to prepare it, erect tents, and provide meals at a charge which, if not exactly those of a Salvation Army shelter, will be sufficiently reasonable for most of those who have responded to the back-to-nature call. Within easy walking distance is the seashore, so that to the delights of camping can be added the pleasures of sea bathing.

Trial runs continue without interruption on the circuit, nearly every French driver engaged in the Grand Prix having made close acquaintance with the triangular course. This week the full Renault team, with the machines to be used in the race, have done a large amount of speeding under the personal direction of Louis Renault. Szisz declares himself thoroughly satisfied with the course and declares that it will be exceedingly fast when the intended improvements have been carried out. During his speeding Szisz killed a number of crows.

The sketch reproduced herewith shows the arrangement of the grandstands, the tire and automobile stations, the loop road, and the score board. It will be noticed that an island is formed between the loop road and the main track, to be united with the outside of the circuit by a tunnel. On the opposite side of the road will be the popular stands and the scoring board. Grand Prix racers will be started at the point marked on the main track, and the Sporting Commission machines will be sent away later on the loop track.

OLDSMOBILE "MUDLARK" DOES 2,000-NON-STOP.

PHILADELPHIA, April 15.—At 8:44 o'clock last Tuesday morning, having been 71 hours and 44 minutes on the road, the Oldsmobile *Mudlark* completed the 1,000-miles non-stop run on which it started the previous Saturday morning. At that time the motor was running so quietly and rhythmically that Manager G. Hilton Gantert, of the Motor Shop, who had charge of the test, decided to continue for another thousand miles. The second leg was completed on Thursday night, and still the *Mudlark's* motor was chug-chugging away as merrily as at any stage of the long journey. But the human element in the test—the operators—were "all in." And reluctantly Manager Gantert gave the word to "stop 'er." But after shutting off the spark, just to show that the motor was as full of life as ever, Driver Folbarth, the Oldsmobile factory expert, started it up a half dozen times on compression. And then all hands went home to sleep.

NEW YORK AUTO CAB SERVICE.

Once more New York is promised an automobile cab service. A new company has recently been organized with the title of the Motor Carriage Company, capitalized at \$1,000,000, under the presidency of G. Winthrop Sands. The New York Cab Company will work in connection with the new organization and will be responsible for the business side of the scheme. The intention is to place three hundred French gasoline cabs, of the type now in use so successfully in Paris and London, in service in New York for private trade only. We are informed by the management of the New York Cab Company that there is no intention to use the taximeter system, but to apply the gasoline cabs entirely to the class of work for which their horse vehicles are now used. G. Winthrop Sands sailed for France this week to make final arrangements with the firms contracting for the supply of the cabs. The vehicles selected will be from the Chenard & Walcker factory, and the Unic make from the Georges Richard factory, and the first delivery will take place about August. The initial batch of machines will have bodies built in Paris by Védrine, but later it is intended to import the chassis only and fit bodies in New York.

The Chenard & Walcker cab has a 16-20-horsepower four-cylinder engine with cylinders cast in pairs and interchangeable mechanical valves on opposite sides. The machine is at present unknown in the United States, but in Europe it has won considerable distinction on account of its reliable construction coupled with low price. Simplicity has been sought in every part, and the machine made as easy to drive and care for as possible—an important feature in an automobile intended for public service. Ignition is by high-tension Simms-Bosch magneto mounted in front of the engine and gear driven off the exhaust camshaft; transmission is through sliding gear, three speeds forward and reverse. Final drive is through a special type of rear live axle.

BROADWAY TO BE RESTORED TO VERDANCY.

As a result of Governor Hughes' signature appended to the Saxe bill, providing for the rehabilitation of the small parks in Broadway, the latter became a law and New York's most picturesque thoroughfare, which has been denuded of every sign of verdure on its island parks ever since the building of the subway, will again blossom forth. The broad strips between the car tracks that did so much to make Broadway shady and cool in the heat of summer, have been eye sores ever since the work of construction on the underground road was commenced. They have been "nobody's dog" from that day on and served as a dumping ground for all kinds of rubbish. Under the new law they will be placed in charge of the Park Department.

Maxwell S. Hart, vice-president and treasurer of the Corbin Motor Vehicle Company, at the wheel.

DURYEA TO BE CONSULTING ENGINEER.

It seems fitting that Charles E. Duryea, who can rightfully lay claim to the title of being the pioneer automobilist in this country, and who has long been a moving spirit in the American Motor Car Manufacturers' Association, should be appointed to the post of consulting engineer of that organization. Than Mr. Duryea there are few engineers in this country who are better fitted for the position. His experience in making gas engines dates back to 1886, and he first devoted his attention to the automobile in 1891, or almost a decade before the motor vehicle began to loom up as a serious factor in daily life. His victories in the *Times-Herald* race in Chicago, the *Cosmopolitan* race in New York City, and the long-distance race in England in 1896, when his car covered 52 miles and finished an hour ahead of a field representing the best that Europe had to offer, as well as finishing a close second in the Belgian race a few months later, are events that will go down into history. He first began to make cars for the market in 1895. The American Motor Car Manufacturers' Association now consists of 41 members, all of whom will be able to benefit by Mr. Duryea's ripe experience in the field of gas engineering as applied to the automobile. How valuable this makes him is apparent when the number of salient features of the present-day auto due to his creative genius is recalled.

FUEL TEST GIVES INTERESTING RESULTS.

Under somewhat more favorable conditions and using a combination of gasoline and kerosene on one of the cars instead of kerosene alone, the fuel test undertaken by the Maxwell Motor Car Company from New York to Boston last winter was repeated on the 6th, when three cars of the same maker were run from Trenton to Atlantic City, N. J., a distance of 103 1-2 miles. Two observers were carried in each car. One of the cars used denatured alcohol, another gasoline and the third a combination of kerosene and gasoline, the different fuels being carried in separate tanks and fed in the proportion of three to five.

Trenton was left behind at 10.25 A. M., the cars being driven by H. A. Grant, using alcohol; Charles Fleming, the combination fuel, and Harry Caywood, gasoline, the first-named drivers having acted in the same capacity on the previous run. On weighing in at the end of the run the cars with passengers and baggage up tipped the scales as follows: Alcohol, 2,560 pounds; kerosene, 2,470 pounds, and gasoline, 2,250 pounds, the fuel consumption having been 14 1-2, 8 and 7 gallons, respectively, the combination car using 3 of kerosene and 5 of gasoline.

Employed by the Linscott Motor Company, of Boston, and is one of its most expert machinists. He is driving a 1907 Reo.

BUFFALO TO HAVE AN AUTOBUS LINE.

BUFFALO, N. Y., April 15.—Buffalo is to have an automobile omnibus line. It will not only operate in the main thoroughfares of this city, but will run to Niagara Falls and surrounding towns. Articles of incorporation of the Auto Transportation Company were filed in the County Clerk's office last week. The company is capitalized at \$100,000. Directors are Blinn Yates, Buffalo; Robert W. Day, Buffalo; Fred B. Eberhardt, Buffalo; Uriah L. Upson, Orchard Park; George J. Klopp, Hamburg. Different routes have been planned in the incorporation papers. Aside from Buffalo's main streets, the lines will extend to Niagara Falls, Tonawanda, Lockport, and towns east and south.

RULING FAVORABLE TO THE CONTINENTAL.

WASHINGTON, D. C., April 15.—Treasury Department regulations of April 28, 1905, providing for the allowance of drawback on Continental tires, imported by the Continental Caoutchouc Company, of New York, and exported with valves of domestic manufacture fitted thereto, have been extended to cover the exportation of tires having outer cases of leather, imported by said firm and fitted with domestic valves, in accordance with the company's sworn statement filed with the collector of customs at New York.

THE LATEST NEWS FROM TIRETOWN.

AKRON, O., April 15.—Akron tire manufacturers report a wonderful increase in business this spring, and all of them are taxed beyond or to their factory capacity. The Diamond Rubber Company has just let a contract for a new five-story annex of concrete and steel construction extending from one street to another. The Firestone Tire & Rubber Company has added several new lines, so that the products now include tires for all standard rims. The company will double its force of workmen in a few months. The Goodrich company has also increased its capacity greatly.

The Firestone company has just put out a new tire known as the Dual tread, which it is claimed will entirely prevent skidding. It is a large tire and is intended for use on heavy motor cars. The tire has two ridges of rubber projecting from the surface of the tire and running longitudinally, one on each side, their outer edges being three inches apart. These ridges run about a half inch from the body of the tire, and by their action prevent skidding. The tire was invented by a workman in the plant, and is entirely a Firestone product.

J. F. Singleton, advertising manager of the Firestone company, has issued a booklet containing instructions for the care of solid motor tires, and it contains information from an expert which has not yet been published.

Charles W. Harris, formerly with the Consolidated Rubber Tire Company, but recently manager of the Chicago branch of the Pennsylvania Rubber Company, has been in Akron closing a contract with the Adamson Machine Company for a large number of molds to be used by the American Cellular Tire Company in connection with the tire which that concern is about to put on the market. This new cellular tire is neither solid nor pneumatic, and those interested in it claim great possibilities for it. It does not puncture, so that no extra shoes or tubes are required to be carried nor are tools or pumps. It is also claimed to be fully as resilient as pneumatics and to weigh little less. The American Cellular Tire Company will not manufacture the tire, but expect to license it. One Akron company is already negotiating for it.

COLUMBIA CO.'S AUTOMATIC ELECTRIC BRAKE.

Not the least interesting feature of the Columbia gasoline-electric chassis that is being specialized by the Electric Vehicle Company, Hartford, Conn., is the provision of an auxiliary electric emergency brake made possible by the unique transmission employed. A 45-horsepower gasoline motor direct connected to the revolving field of an electric generator with a dragging or slipping armature is the power plant and elastic clutch of this car. Mounted on the armature shaft of the generator, which runs back to the axle, is the armature of the stationary field motor, into which all the current produced by the slip of the generator field is retransformed into mechanical energy and aids in driving.

The auxiliary electric emergency brakes are embodied in this stationary field motor, and by simply pulling the controller handle to the first rear notch on the control this field and its armature are short circuited and tend to turn as one. As the field is rigidly fastened to the frame of the car, this is impossible, and the driving mechanism locks with a slight slip. The feature which appeals strongly to the more careful autoist who tours hilly country is the automatic retarding brake, which acts in the capacity of the sprag or ratchet. In this automatic sprag is found probably the only brake in existence which goes into operation the moment the car begins to travel backward without any assistance whatsoever from the driver. It is caused by the motor armature on the driving shaft generating current as soon as the armature commences to revolve backward, thus causing a powerful brake, with a slight slip, which will hold as long as the wheels have traction.

Peoria, Ill.—Two new garages now under construction in this city are nearing completion. One is located on East Pine street, and the other on North Main street.

PITTSBURGH'S SHOW WAS RESULTFUL.

PITTSBURG, PA., April 15.—A success. That sums up the opinion of the first automobile show in Pittsburg. It closed last Saturday night in a blaze of social brilliancy. The show was still more of a success in point of sales. Over \$400,000 worth of cars were actually sold during the week. The Central Automobile Company sold 20 Reo cars and two Grout cars. J. G. Warwick & Co. sold 29 Jewel cars. These were two of the best records made, but only two. There were a dozen agencies which sold half as many cars as they have in any one month of this season. The sales continued up to the very hour of closing, the last purchase, a Winton car, being made after 11 P. M. Saturday by the Hon. James Francis Burke, Congressman from Pittsburg, as a present to his wife. Instead of the show being a loss to exhibitors it made them a lot of money in direct sales as well as in the splendid advertising which they received from it.

The show was not without its features. One of these was the exhibit of the Standard Automobile Company. It had to borrow cars from its customers to make a showing, as all its Packards and Franklins were sold before the show opened. Another feature of the week was the big hit made by Guenther's orchestra in the new "Pittsburg Automobile Association March."

The show was handicapped by the refusal of the Motor and Accessory Manufacturers to grant a sanction for the exhibit of accessories and parts manufactured by members of the association. Strong pressure was brought to bear to secure this permission, but it was withheld. Pittsburg dealers are still angry.

An automobile show in Pittsburg for next year is an assured fact. If a "first show," coming the same week as the Carnegie Institute festivities and in the midst of weather that would drive anyone but an enthusiastic automobilist indoors, can be made such a success as last week's event, it is believed that with this experience Pittsburg can have next year a show that will be international in its features. The show will likely be held earlier than this year. The committee who managed this show consisted of W. H. LaFountain, Thomas I. Cochrane, and Earl Kiser.

A STAGE FAVORITE'S USE OF AUTOS.

BALTIMORE, April 12.—That autos are taking a place on the stage will be shown next week at Ford's Opera House. Miss Jessie Busley, who is to play *Nance* in "The Bishop's Carriage," has decided to make her escape in a Baker electric. Miss Busley gained much notice by traveling the Pacific Coast in automobiles. She went from San Francisco to a number of other cities, carrying both company and baggage in autos.

THE "DIP OF DEATH" LADY IN HER AMERICAN MORS. — A feature of the Barnum & Bailey Circus, at Madison Square Garden. Mrs. Isabella Butler is the heroine of the act.

BRIEF ITEMS OF NEWS AND TRADE MISCELLANY

A total of 18,889 automobiles are in use in Massachusetts according to figures just published by the registration authorities at Boston.

Additions have been made to the Providence branch of the Angier Company, at 9-11 Dorrance street, by the incorporation of the adjoining store. W. B. Richards, formerly of New York City, is the branch manager.

Among the orders received last week for Truffault-Hartford shock absorbers was one for fifty sets from Julius Bindrin, the Bedford avenue dealer in Brooklyn. This year is expected to be a record one for the pioneer device.

Information has been received from Michelin headquarters in France by E. Lamberjack & Co., sole American agents for Michelin tires, that Panhard, Renault, Fiat, Bayard-Clément, Itala, De Dietrich, and Darracq racing machines will use Michelin tires in all national and international races in 1907.

Extensive improvements and enlargements have been made to the wood-working plant of Miller Brothers, of Amesbury, Mass. The firm, which has been engaged in body building for eighteen years, had an output of 2,500 bodies last year, and with the increased facilities will turn out 4,000 bodies in 1907.

The Locomobile Company report that they have shipped from the factory at Bridgeport over 60 per cent. of the 1907 output, and that their sales department has never been in such a healthy condition—a statement which, although general, must be regarded as significant. The record shipment was made recently, \$60,000 worth of Locomobiles leaving the factory in a single day.

Harry Dunn, president of the Fisk Rubber Company, of Chicopee Falls, Mass., is in New York in order to pass on the final details of the building which his company is erecting at Fifty-fifth street and Broadway. The plans for this building are very elaborate, as it will be used as a distributing center for much of the Fisk Company's business. Owing to rapid growth in popularity of the Fisk detachable tire, Harry Fisk, the treasurer of the company, will devote his personal attention to the local branch.

If the intentions of private owners are to be counted on, Columbia cars will figure conspicuously in the big motoring events on the 1907 calendar. Two Columbias are already entered for the American Gold Cup Tour, and assurances are given that at least four machines of this make will participate in the Glidden Tour. Charles F. Barrett, who last year finished the tour with a perfect score in a 24-horsepower Columbia, is undecided whether he will enter the Glidden Tour or the European event.

Amesbury, Mass., is to have a large factory devoted exclusively to the building of metal bodies. A company has been formed under the title of the Amesbury Metal Body Company, and has secured a large, centrally-located factory with 20,000 square feet floor area, which is now being remodeled and machinery installed. The plant will be in operation at the beginning of June. The heads of the new company are J. Albert Davis, formerly of Gray & Davis; James H.

Walker, of Walker Carriage Company; John Foster and Fred England.

Thomas Henderson, vice-president of the Licensed Association of Automobile Manufacturers and of the Winton Motor Carriage Company, has returned to Cleveland from a month's trip through the far west. "I was astonished at the remarkable prosperity of the western country, particularly of the Pacific coast section. San Francisco, now in the making, will be greater and better than ever before. There are wonderful business opportunities on the coast for young men of ability, especially in the sale of automobiles. Motor cars have so emphatically demonstrated their usefulness under severe conditions, in cities, country and mining camps, that sales are made to far western buyers with considerable less effort than in the east, where details rather than general practicability wield an influence out of proportion to their importance. Western buyers lack nothing in shrewdness and they demand the best cars, but what they demand above all else—in their level-headed way—is power and durability."

NEW AGENCIES ESTABLISHED.

The Craig-Toledo agency for Northern California has been placed with the D'Arcy-Scott Company, 524 Golden Gate avenue, San Francisco. This concern also represents the Dragon car.

Two new distributors have been appointed for the Cleveland by the Cleveland Motor Car Company, as follows: C. W. Poole, 714 Sixth avenue, Seattle, Wash.; Van Automobile Company, 4706-4710 Washington avenue, St. Louis.

The Angier Company, of Boston, has opened a branch for the sale of marine engines and motor boats at 31 Central Wharf, that city, and has secured the agency for Bridgeport motors and Ferro engines. John R. Parker is the new manager.

PERSONAL TRADE MENTION.

George S. Atwater has resigned the position of sales manager with the Atwood Manufacturing Company, of Amesbury, Mass.

C. L. Lawrance, of the B-L-M Motor Car Company, will sail for Europe April 19 to visit the Krupp steel plant and other European institutions in the interests of his concern.

Otis R. Cook, formerly of Cleveland, and for a dozen years traveling agent for the B. F. Goodrich Company, has taken a position with the Firestone Tire & Rubber Company, and will travel between Buffalo and Toledo.

Theodore Goetz, for some years connected with the R. E. Dietz Company in its automobile lamp department, has joined the selling force of the Witherbee Igniter Company. W. W. Robinson has joined the engineering force of the Witherbee Company as mechanical engineer.

E. C. Angell has resigned as general superintendent of the Jones Speedometer to accept the general management of the Winchester Speedometer

Company, in which corporation he has a large interest as a stockholder. Mr. Angell has been long known to the manufacturing world.

John J. Coakley, a former Boston newspaper man, well known as a writer on automobile topics, has taken charge of the publicity and advertising department of the Babcock Electric Carriage Company, of Buffalo, N. Y. C. H. Tyler, for six years eastern representative of the National Motor Vehicle Company, has joined the selling force of the Babcock Company.

Charles Schmidt, the designer of the 1907 cars manufactured by the Peerless Motor Car Company, of Cleveland, O., sailed on *La Lorraine* April 4 for a trip abroad. Mr. Schmidt expects to be gone about six weeks, and will visit all the important European automobile manufacturers, renewing acquaintances and studying new foreign methods of construction and materials used.

James K. Christie, who recently withdrew from the firm of Palmer & Christie, importers, has joined the forces of the American Locomotive Automobile Company, his position being designated by General Manager Joyce as "manager city sales." Mr. Christie's identification with the automobile business dates back to 1900, when he was selling steamers. He has been in the importing line since 1904.

H. A. Williams, 1459 East Eighty-eighth street, Cleveland, O., inventor and formerly manager of the Williams New Electric car and New Gasoline car, has severed his connection with the Williams Electric Vehicle Company, the reason given being a stockholders' disagreement. Mr. Williams expects to organize a new company or join some other concern which will manufacture his electric car.

NEW BUSINESS ENTERPRISES.

Charleston, S. C.—The Automobile & Marine Motor Company has been incorporated by N. S. Lea as president, J. C. D. Schroeder as secretary, and W. Orrin Bee as manager. The company has the agency for the Ford and the Detroit, and will carry a complete line of sundries. Located at 9 George street, the company occupies a two-story building, 40 feet wide by 160 feet deep.

New York City.—The Imported Car Repair Company will install in the Motor Mart at Broadway and Sixty-second street a machine shop for the purpose of repairing the highest grades of automobiles. A specialty will be made of magnetto work. The officers of the company are: President, M. S. Gilmer; secretary, R. B. Whitman; treasurer and manager, J. T. Gilmer; chief mechanic, C. W. Adams.

Goshen, Ind.—Leading business men of this city have organized the Oswald Motor Company for the purpose of manufacturing gasoline automobile and marine motors, and will place on the market single-cylinder and double-cylinder types and also a 40-horsepower motor. The officers of the corporation are as follows: President, Elmer Newell; secretary, Charles Shoup; treasurer, O. M. Curtis; sales manager, W. T. Miller.

St. Louis, Mo.—The D. L. G. Auto Company, of 3032 Olive street, is being organized by A. L. Dyke to manufacture the Dyke-Leibert & Givens six-cylinder "unit power plant" automobile. The features of the new car as announced are the improved unit power plant, consisting of six-cylinder engine, 4 by 4 1-2, with multiple disk clutch and selective transmission housed in unit, also the absence of coil batteries, and high-tension magneto used instead. The company expects to have a model completed in sixty days, and a run will be made from St. Louis to New York without the use of battery or coil.

Jersey City, N. J.—The Acetylene Specialty Company, with a capital stock of \$100,000, has been incorporated to manufacture small acetylene cylinders (Parisian style) for automobiles and other purposes under the name "Stereo;" also a new high candlepower acetylene incandescent burner for auto lamps. The incorporators include Eugene Bournonville, ex-chief engineer of the Commercial Acetylene Company, and E. Thomey-Cavalleris, president of the Acetylene Gas Illuminating Company, of New York. The factory will be located in this city and the general offices of the company at 105 Walker street, New York City.

NEW TRADE PUBLICATIONS.

Air-cooling is naturally the theme of the Frayer Miller 1907 catalogue, which has just made its appearance. For the coming season the firm has produced a 50-horsepower model of long wheel base and seating accommodation for seven passengers. This is fully described in the catalogue and the distinctive features of the Frayer-Miller system of cooling by a blast of cold air is explained by text and drawings. A copy of the booklet can be obtained from the Oscar Lear Automobile Company, Columbus, O.

Though they are both self-propelled, there is not much similarity between a road roller and an automobile. Yet road rollers make good roads; good roads make automobilists happy. The good road makers of the Monarch Road Roller Company, Groton, Tompkins County, New York, are presented to the public in a new catalogue issued by that body and containing many half-tone illustrations and much descriptive text. Street cleaners, water wagons and portable engines also find a place in the new publication.

"Expert Testimony" will be read with interest by all automobilists. Extracts from the reports of the correspondents of the leading automobile journals in America on the annual automobile shows of London, Paris and New York are given in the book, each one being followed by a few words of text showing how the Lozier machines conform to the best ideas to be found in these great exhibitions. A word to the Lozier Motor Company, Fifty-fifth street and Broadway, will bring "Expert Testimony" to any who desire it.

Artistically designed, well printed and elegantly bound, the new Rambler catalogue is in every respect a pleasing production. Panels and vignettes of those wayside scenes that every true automobilist is always delighted to find, contrast harmoniously with the half-tones of complete cars, chassis and mechanical parts of the 1907 Rambler output. There is plenty of text also, and

not a feature of the machine but is thoroughly described. The catalogue can be obtained from the Thomas B. Jeffery & Company main office at Kenosha, Wis., or from their numerous agencies.

"Instructions and Directions for Operating the Great Smith Car," published by the Smith Auto Company, Topeka, Kansas, is a voluminous work of 64 large pages, containing a quantity of useful information. Dealing first with general considerations of the automobile, the work passes progressively through the entire mechanical field of the internal-combustion engine, clearly explaining many of those principles without a knowledge of which it is almost impossible to successfully operate an automobile. A separate chapter deals with the practical operation of an automobile under all conditions, from cranking the engine to difficult driving on the heaviest of roads. Common ignition troubles, attention to tires, grinding valves, attention to lubrication, water circulation and other matters which every automobilist must learn are among the subjects on which the instruction book gives advice.

Manufacturers have learned that a large amount of a customer's satisfaction lies in his or her ability to operate and care for a motor car properly. The Peerless Motor Car Company has issued a most interesting and attractive pamphlet, "The Peerless Instruction Book," which explains in a clear and concise manner the detailed construction and operation of this company's cars. Of course, it is impossible for any book to solve in advance all motoring problems that an operator will encounter. But this description and the general hints contained in it will give a new operator a valuable foundation on which to build further knowledge of the more minute details of a car, and at the same time form a safeguard against possible costly errors in care and operation. The book starts with a description of the lubricating, gasoline ignition and cooling systems, then giving description of the motor, transmission, brakes, etc., and closing with some valuable hints on proper operation, common sources of trouble and, lastly, with a list entitled "A Few Don'ts."

INFORMATION FOR BUYERS.

Storage Battery Charger.—The object of the storage battery charger just put on the market by the A. W. Fisher Company, of South Bend, Indiana, is to keep an ignition storage battery charged while the engine is running. It is installed on the motor, to be driven either by belt or by friction pulley against the flywheel, and generates current which is stored in the battery, taking the place of that which is being used by the coils, thereby keeping the battery charged constantly. The plan contemplates using current from the battery at all times, the charger simply supplying what is needed to keep the battery charged. This amount is arrived at in the construction of the machine, the output of the armature not being sufficient to injure the battery in any way, but enough to take care of the consumption by the coils. It is provided with a patented mechanical automatic circuit-breaker, or switch, so constructed that it breaks the circuit between the battery and charger when the speed falls below that at which it is generating current, and prevents the current from the battery leaking back through the machine and exhausting the

battery. This cut-out, which is a part of the charger, operates entirely by speed and does not depend upon the electrical output of the generator. The entire machine weighs but 12 pounds and measures

FISHER'S STORAGE BATTERY CHARGER.

8 1-2 inches long by 5 inches high by 4 1-2 inches wide. Any standard 6-volt battery may be used in connection with this charger. The machine is sold under a positive guaranty that it will keep an ignition storage battery charged and ready for service at all times.

National Speed Indicator.—Driven from the road wheel by a flexible shaft in the usual manner, the National speed indicator is actuated by a vertical ball governor mounted in ball bearings and working against a balanced spring, this principle insuring a uniform scale and accurate reading. The scale is nine inches long and is claimed to be the longest on the market; the needle is as steady as a clock hand and the face so open that it can be read in a very dim light. All the moving parts are of steel,

NATIONAL INDICATOR AND FIXTURES.

the shaft cases are of flexible brass lined with a special steel lining, and all attachments are made strong to stand hard

A Veeder odometer inclosed in the case and reading through the dial gives the season's mileage; there is also a resetting trio register for 100 miles and repeat. The National indicator is manufactured by William Herbert Jones, Newton, Mass.

THE AUTOMOBILE

WE had come down the Rhone Valley in a howling mistral. The dread north wind was at our backs, but it blew with all its wonted fierceness and gave a good five kilometers an hour more than our normal speed, though curiously enough when we had come up-river against it on one occasion our average of forty kilometers—which is not bad for a light-powered automobile—fell to twenty-five, with everything pulling well at that. The plague of the mistral is classic throughout all Provence, and there is a saying among the habitants of old that all Provence needed to make it a veritable Eden was the abolition of the Parlément, the suppression of the mistral, and the damming or drying up of the river Durance, which of all the enigmatical and torrential rivers of the world is the most unstable and fickle. Madame de Sévigné in her time was a good observer of things as they were, and she passed many strictures on the topographical features of France which have been very useful to us writers who have followed after. She called the mistral an unchained devil, and she knew, for it blows and howls around the Chateau de Grignan in an inconceivable manner, as it does through all this otherwise delightful region, when once it arises in its wrath.

Automobilists to the south of France had best come down by the Rhone and return north via the Pyrenees if time will permit. It is the only way to be sure of avoiding one of the stiffest winds that blow for a matter of 300 kilometers.

We were bound for the Italian frontier, and did not propose to linger by the way, but the spell of Provence was upon us and, after leaving Valence, and realizing the full force of the adage, "*A Valence le Midi commence,*" we fell into that languor of *laisser aller*, which comported little with scorching off kilometers at *toute vitesse*. Without question Provence is the true land of *la cigale*.

Before we knew it we were on the trail of Daudet's Tartarin and Dumas' Monte Cristo, and the hero-worshipping instinct of the literary vagabond came to the surface with such rapidity that we could not down it and so decided to make a little literary pilgrimage forthwith.

One of the charms of French travel by road is the frequency with which one picks up these literary trails; not even in England are they more numerous nor e'en so romantic.

A New Motive for Automobile Tourists.

Here's a new motive for automobile tourists; let them follow up some previously outlined literary or, for that matter historic, itinerary and get a pleasure and edification out of touring that they knew naught of when they were hying from one resort to another and stuffing themselves with imitation Parisian table d'hotes and wine at five francs the bottle and plus; when they could do far better, from every point of view, in the small towns through which they passed and didn't even know by name.

Old Provence is full of literary landmarks. Alphonse Daudet, Frederic Mistral, Félix Gras, and Dumas père have left the footprints of their characters as thick as falling leaves in autumn and no more pleasurable occupation can be conceived than the locating of some of these spots in the real.

With these thoughts in mind we pulled up before the Hotel des Empereurs at Tarascon, an hour before déjeuner, rather than push on forthwith to Arles as we had planned; "*les belles Arlésiennes, Grecques aux yeux de sarazine,*" could wait.

The town of Tartarin is no myth, though Daudet's leading actor—whose chief pleasure was hunting imaginary beasts—was only given a domicile here because he had to live somewhere, and because the Provençal is more or less a guileless braggart and blunderer in all things. This is not saying that he is not a good sort; indeed, the reverse is the case, for he is the most lovable of all the indigenous inhabitants of the old French provinces. Daudet gave his worthy bachelor a residence here simply because he was a true

child of the Midi, and Tarascon is as typical of the Midi of France as any other place still on the map.

"*Tarascon! Cinq minutes d'arrêt! Changez de train pour aller à Nîmes, Montpellier et Cette!*" This is about all the average

LES BELLES ARLESIENNES.

traveler knows of Tarascon: then he suddenly remembers Tartarin and looks up the town in his guide-book to see what else it stands for.

Nearing the Real Southland.

The automobilist is considerably better off. For a hundred kilometers he has been drawing up on the real southland until now olives and cypress trees in the landscape, and olives and garlic in his food (to say nothing of the *beurre de Provence*, the most strikingly pungent mayonnaise that was ever concocted) are no longer novelties.

Tartarin, as we know, had no real existence, but the entire locale of Daudet's tale is reminiscent of every kilometer of Tarascon's cobblestoned streets, and every jalousied veranda of its house fronts, and every stone of its old chateau of Roi René, the church of Ste. Marthe, and its proud old Hotel de Ville. Daudet's description of all this is exceedingly real; one should reread it on the spot: "*Tarascon, a little patch of Provence on the Rhone opposite Beaucaire.*"

Twelve thousand people live here, and it is a great railway junction and workshop, but for all that the automobilist in search of a *mécanicien* will do well to wait until he gets to Arles, or

about of its crops and even beasts and little children. There are two yearly fêtes which celebrate the suppression of this hungry monster of days gone by which are as quaint and curious ceremonies as the dragon processions of the Chinese. The "tarasque" of to-day is led in chains tranquilly through the streets, but his tail lashes out as of yore and the groans and growls terrify the young idea as they did the fleeing Tarasconais of all ages long ago. "The good king René" inaugurated the fête in 1469, and only when a parsimonious board of city fathers gets into office it is still a yearly event which draws crowds in thousands from all over Provence.

At Beaucaire, on the opposite bank of the Rhône, is the fine ruin of a crumbling old chateau contemporary with that of Tarascon, but perched high on the river bank in a most commanding situation.

The famous "Foire de Beaucaire," first instituted in 1217, was once the rival of that of Guibray in Normandy, and both were the precursors of the great fair of Nijni-Novgorod of to-day. Now the fair of Beaucaire is simply a *foire-marché* and a *fête-foraine* such as hundreds of others to be seen all over France, but within a hundred years it still reflected some of its former splendor and

BEAUCAIRE, FROM THE RHONE.

THE TARASQUE.

CHATEAU OF KING RENÉ.

to trace his wheel-tracks back to Avignon, provided his wheels will go round.

The Tarasconais resented loudly what they were pleased to call Daudet's caricature of them, but all the same Tartarin—*coquin de sort*—was not at all unlike many that one may see to-day sipping his "*Pernod*" or his "*Amer*" at the popular café of Tarascon's tree-shaded Cours or promenade at the aperitif hour.

Daudet described his hero as a "Don Quixote in the skin of a Sancho Panza," and the portrait will remain forever unaltered and unobliterated, and it will fit, too, many a real Provençal without being the least bit of a caricature.

He would be a great traveler—Tartarin, would have founded an empire across the sea, hunted lions in Africa, and done many other venturesome things—chiefly by word of mouth, but in the end he bought up a "dying exile" at Beaucaire, a scant kilometer away from Tarascon, across the ugly iron bridge which spans the Rhône.

Where King René Once Reigned.

The Chateau de Roi René is the very ideal of a building-block chateau. It bathes its foundations in the surging Rhône and its crenelated battlements and its shot-scarred walls form a story-telling picture of much vivid history that has been made within sight of it.

But a step around the corner from the hotel is the Eglise Ste. Marthe, whose founder suppressed the ravages of the dreaded "tarasque" all through the neighboring region. The "tarasque" was a beast, a sort of a cross between a dragon and a reptile, of enormous size, who lived only by devastating the country round-

magnitude when merchants came from Persia and the Indies and Arabia and Constantinople to vend their wares in this turgid Rhôneside town.

Tracing the Count of Monte Cristo's Footsteps.

Leaving this little corner of Daudet's country behind, not having been able to locate his "*Moulin*," which we had always suspected was in these parts, but which we were assured had not a real existence, we set out to trace the footsteps of Dumas' Edmond Dantes of Monte Cristo fame in the immediate neighborhood.

Disguised as the gentle Abbé, Dantes came here to the banks of the Rhône to pay a surprise visit to the unworthy Caderousse and his still less worthy spouse, two flinty-ribbed and harder-visaged characters of fiction which have never been excelled as portraits of villains by force of circumstance.

Caderousse and his wife had become inn-keepers at Bellegarde after having fled the tailor-shop in Marseilles, a dozen kilometers from Beaucaire on the Montpellier road.

The beauty and charm of these byroads of the south of France is that no matter how unfamiliar they may previously have been they invariably seem like old friends to the automobilist by reason of the facility with which he finds his way over them—great long silent stretches of marbly-white road, and often with ten kilometers straight-away without so much as a *caniveau* on them.

Automobiles are frequent enough passers by and through Bellegarde, but literary pilgrims are few. At any rate, there is no house there to-day corresponding to the mean, rough little inn beside the canal wherein Caderousse and his wife plundered witless travelers—the Hotel du Pont du Gard. There is an inn of

sorts, the Hotel Gédéon, and Dumas' description of its sun-burned, lonesome surroundings is good enough to fit. The only thing that doesn't apply is the fact that there is a fair sort of accommodation to be had, or at least a plentiful and gratifying meal may be had, with astonishingly good wine grown on the vineyards roundabout. Anyway, we were glad we came; it was an entirely untouched and unspoiled little corner where the thousand souls who call Bellegarde their home for the most part of the year while away their existence and read "Lou Armana" as regularly as the head of the New England farmer family, snow-bound in winter, reads the "Old Farmer's Almanac."

Frequently Pass, But Do Not Stop.

Automobiles frequently pass this way, but despite the old-world charms of the place, they seldom stop, judging from the commotion which our modest outfit brought about. The maid of all work at the inn was so staggered and amazed that she treated us with that fear and deference that she might have had for a stranger from Mars, glancing inquiringly from ourselves to the machine. "Damel!" she said, "*vous allez si vite, avec cette machine là. Combien pouvez vous faire de kilomètres dans une heure?*" "Oh, forty or fifty," replied the author of these lines—the chauffeur. "Oui. . . c'est beau, cette chose là! Mais est-ce que ce n'est pas dangereux?" Well, sometimes, perhaps, it is, but we assured her

HOTEL DU NORD, ARLES.

we were most temperate in all things and would not even run over a *belle poule* if we could help it.

Within an hour we were at Arles and settling down for the night at the Hotel du Nord on the Place du Forum—not the Hotel du Forum on the opposite side of the square, but the competing establishment which has a portion of the old Roman forum built into its outer wall.

For a fact, there's not much choosing between these two hotels; they both lack the character and local color of the country, and have in recent years been refurbished up and improved over what they once were until they are simply ordinarily good large-town hotels and nothing more, even though they be efficiently conducted. Garage accommodation is good at each, though limited.

Arles is an anomaly. Its hotels and cafés and some other things are modern and comport little with the very substantial relics of Roman arenas, tombs and palaces which link the city so closely with the romantic past, but for all that Arles is the most fascinating, though perhaps not the most livable, of all the towns of Provence, not the least of its attractions being the beautiful women with their old-time Greek profiles and their little top-knot coiffes, so dainty and charming that the susceptible—automobilists and others—put them well at the head of nature's portrait gallery of beautiful women.

[To be continued.]

WINNING THE MOTOR CHAMPIONSHIPS OF THE SEA

MONTE CARLO, April 16.—A blue sky, a brilliant sun, the water unruffled by the slightest breeze, and a dense crowd on the steep banks of Monaco Bay, were the accompaniments to the first day's racing of the fourth annual international meet.

Excitement was high when the six racers in the 26-foot class lined up for the 50-kilometers contest. *La Rapière II.*, the Panhard and Tellier combination, was the favorite; *Fiat XV.* and *Itala* were the Italian champions; *Seasick*, Itala engines and French hull; *Mouvette*, French hull and engine, and *Anadyomene*, a Franco-Italian craft, were looked upon as less formidable opponents in this contest.

At the last moment *Anadyomene* starboarded her helm and made for port; evidently her crew feared a recurrence of the previous day's proceeding, when, owing to her high Delahaye motor, the boat capsized. Soon *Rapière II.* and *Fiat XV.* were in the lead, rushing over the glassy surface at an amazing speed. The French boat made a better start, and maintained her advantage for some time, but seemed to be losing slightly to the *Fiat*. Tellier, how-

ever, shaved his boat round the buoys in a masterly manner, while the Italian boat went about very clumsily. At the end of a round the *Fiat* missed fire a few times, stopped, but a second later was off again. The second had lost him his position, however, for the *Rapière*, with its Panhard motor turning with clock-

work regularity, had got far ahead, and Baron de Caters had pushed his *Seasick* into second position. Tellier had no longer a serious competitor, and finished the race a good first. *Seasick* and *Fiat* continued to struggle for second position, and it was not until the fifth round that *Fiat* got ahead of her rival; had she been better steered round the buoys she would without any doubt have made much faster time, despite the trouble with her carbureter. *La Mouvette*, with her 24-

PANHARD-TELLIER WINNING 200-KILOMETER CHAMPIONSHIP.

horsepower Mutel motor, was no match for the more powerful boats, and finished the race at an easy gait. *Itala* had to abandon the race owing to lack of water circulation. At high speed her bow was quite out of the water, and her water inlet, which was placed forward, was high and dry. *Rapière*, on the other hand,

MAIS JE VAIS PIQUER, WHICH WON THE CRUISER RACE.

maintained a perfect water line, and covered her fifty kilometers without any fuss in 55:55 1-5, or at the rate of 33.3 miles an hour, nearly fourteen minutes faster than last year's winner.

Twenty-one boats started in the 50-kilometers cruiser race, *Capolou III.*, with a Mutel motor, being first at the rate of 20.8 miles an hour. Nine finished, three abandoned, and the rest were running when the race was called off. The day's results were:

26-FEET RACERS, 31:06 MILES.

1. La Raplère II, Teller Fils & Gerard hull, Panhard motor, 55:55 1-5. Average, 33.3 miles an hour.
2. Flat XV, Caroni di Streza hull, Fiat motor, 57:36. Average, 32.8 miles an hour.
3. Seasick, Teller Fils & Gerard hull, Itala motor, 1:1:50. Average, 30.1 miles an hour.

Owing to a heavy swell it was necessary to postpone the contest for racers on the second day, and even the cruisers were, with a couple of exceptions, unable to cover the fifty kilometers. The *Mais je vais Piquer*, a Swiss boat, took first prize

Racers Make Fast Time in Bad Weather.

The big racers made their first appearance on the third day of the meeting in a 50-kilometers contest over a rather rough sea, when the *Panhard-Tellier* proved herself the fastest and the most seaworthy race that Monaco has ever seen. Seven started, but on the first round *Daimler III.*, the English boat, dropped out unable to stand the buffeting of the heavy sea at high speed. Thubron's craft, the *New Trefle* with a Brasier motor, had to give up on the second round, owing to weakness having developed in her hull just under the engine; at the same time *Daimler II.*, the wood boat constructed by Saunders and fitted with three six-cylinder motors by the Daimler Company, had to make for port in a pitiful condition. Chevalier Florio's *Jeanette*, with an Itala motor, abandoned during the third round; *Flying Fish* ran for home on the fourth round, thus putting all the British boats, which were looked upon as dangerous competitors in a heavy sea, entirely out of the race. France and Germany were left for the final struggle, the former represented by the *Panhard-Tellier* and the latter by the *Mercedes D. L.* The three-ton French craft, propelled by its 250-horsepower Panhard motor, was marvellous for speed and for seaworthiness. At thirty-four miles an hour she took the head seas in perfect style, cleaving the waves in a manner that called forth admiration from both friends and rivals. The *Mercedes D. L.* showed remarkable seagoing qualities, but her speed was much inferior to that of her rival. The French were jubilant, for their boat had, in bad weather, beaten all records established in calm water at any previous Monaco meeting. The official results were:

50-KILOMETERS RACE FOR BOATS ABOVE 26 FEET.

1. Panhard-Tellier, Teller Fils & Gerard hull, Panhard & L'vassor motor, 54:27 1-5. Average, 34.2 miles an hour.

2. Mercedes D.-L., Decout-Lacour hull, Mercedes motor, 1:42:56. Average, 18.1 miles an hour.

In the cruiser section *La Lorraine* broke world's records by covering 50 kilometers at an average of 25 miles an hour. The boat has a Lorraine-Dietrich motor, and the hull was built by Perignon. *All'Erta*, an Italian boat with Fiat motor, took second place. The hydroplane race was devoid of interest.

Panhard Establishes World's Long-Distance Record.

French jubilation reached its height when, in the championship of the sea, a 200-kilometers open race for all classes, Comte Robert de Vogue piloted the *Panhard-Tellier* to victory at an average speed of 35.01 miles an hour, the fastest rate ever attained by any craft. The same boat's previous average on the 50-kilometer course, and that of her companion *Rapière*, were surpassed by a large margin, while the performance of *Delahaye*, the victor in last year's championship, at 26.6 miles an hour, looked like a dog trot in comparison.

On a perfectly calm sea, and under the gaze of twenty thousand spectators, the twenty boats got away in a compact mass. *Panhard-Tellier* soon shook off its competitors, and was only harassed a little by the *Fiat XV.*, piloted by Taroni. The Italian boat, however, had not the fine lines of the *Panhard-Tellier*; her bow was too far out of water, and her skin friction was greater than that of her rival. For three rounds *Panhard-Tellier* remained ahead, with *Rapière* and *Fiat* following her.

There was an interesting match between *Ulysse* and *Sec*, both with Mors motors, terminated by the withdrawal of the latter at the fifteenth round. *Flying Fish*, the Wolseley racer, ran regularly, but was slow. Thubron's *New Trefle*, with Brasier engines, only showed speed at intervals, and the *Mercedes D. L.* proved more of a cruiser than a racer. After an exciting struggle with *Lorraine II.*, the Italian cruiser *All'Erta*, shook off her French rival and secured second place. The cruiser *Ulysse*, with a Mors motor, obtained third place. Official positions were:

CHAMPIONSHIP OF THE SEA, 200 KILOMETERS.

1. Panhard-Tellier, hull built by Teller Fils & Gerard, engines by Panhard, 3:33:4. Average, 35.01 miles an hour, world's record.
2. All'Erta, cruiser, hull by Gallinari, engines by Fiat, 4:36:27. Average, 26.1 miles an hour.
3. Ulysse, cruiser, hull by La Sirene, engine by Mors, 4:59:49. Average, 24.8 miles an hour.
4. Flying Fish, racer, hull by Saunders, of London, engine by Wolseley, 5:14:13. Average, 23.7 miles per hour.
5. Adele, cruiser, hull by Baglietto, engines by Delahaye, 5:16:3. Average, 23.5 miles per hour.
6. Mercedes D. L., racer, hull built by Decout-Lacour, 7:53:6.
7. Pilote I, kerosene pilot boat, hull by Société des Vedettes Automobiles, engines by N. W.

THE MARINE RACE COURSE AT MONACO.

FIRST AUTO IN THE CANADIAN COBALT COUNTRY

By A MICHIGAN EXPLORER.

A TELEGRAM had come from Cobalt, Ontario, stating that automobiles were impossible because of the impassable roads. The manager of the Canadian Bank of Commerce had sent the information, which, instead of deterring the writer, made

WHEN THE CADILLAC MADE ITS DEBUT IN COBALT.

him the more eager to show that good roads were not an absolute necessity for a Model M single-cylinder Cadillac and that it could go anywhere where horses could travel.

The inhabitants of Haileybury, Ontario, center of the Cobalt or Temiskaming mining district, watched the entrance of the car into their city with wide eyed and all absorbing interest. Horses took an entirely different view of the matter and made strenuous efforts to get to the tall timber. Few people of Haileybury had ever seen an automobile before. The town proper is built on the side of a grade of about 15 per cent, and it was up, down, and sidewise on this grade that we were compelled to operate from the start.

Originally Haileybury was just a camp. The houses or shanties looked as though someone had stood out in the lake and thrown them at the side of the hill. If they landed facing north, south, east, or west, it was all right, but their proximity to each other did not matter at all. But last Fall a fire came along and now there's a new Haileybury on the map. It claims to be a city with streets. It has two: one of them runs from the railroad station to the lake; the other crosses it. Haileybury claims to be the center of all the Temiskaming mining country, as perhaps it is. It has several hotels, each one with a big, lively bar in connection; has a De Forest wireless telegraph station; a steam fire engine, and a free library and reading room. Truly it is metropolitan.

After having satisfied ourselves and the people of Haileybury that there was nothing in the town that we couldn't climb up or go over, we started to New Liskeard, another mining town some five miles away. In many instances the roads encountered were beyond description. Over these roads had been hauled the heaviest of logs the entire Winter, and on sleds that were not standard width by about twenty inches, necessitating the breaking through with one front wheel of our car of about four feet of snow and slush, and in many instances fairly dragging the body of the car on the ice and snow in the center of the road where it was firmly packed. Grades of from 15 to 20 per cent. were found to be usual instead of exceptional. We were frequently offered tows by the accommodating loggers and teamsters, but in no case were we compelled to accept them, as the car, by digging out and prying up, was able to make its own way. In only one instance on the road from Haileybury to New Liskeard did we meet any serious difficulty, and this was when

the car was mired in snow and slush until the drive wheels fairly spun round, with nothing on which to hold. It was necessary here to secure logs, sticks, etc., and pile under the wheels for something like forty rods, enabling them to take hold and extricate the car. Two miles and a half of this road was endured when we found a place that by almost letting the car fly we could get down to Lake Temiskaming. We made the balance of the distance on the ice.

The return from New Liskeard to Haileybury was without incident of any kind, being made over the ice, driving the four or five inches of slush and water in many places 25 and 30 feet on either side of the car. The four and one-half or five miles were covered in some twelve minutes.

The following day a trip was undertaken from Haileybury to Cobalt. Quite a crowd of people collected about the car before starting, and the accommodating livery man offered to send teams along to drag us out of the holes that they predicted we would never be able to get out of under our own power. We thanked them very kindly, however, and started. In no place in the United States will roads be encountered such as are met with from Haileybury to Cobalt. One is either on the top of the mountain, or else plowing his way through a swamp, or sliding down, or crawling up, or skidding sidewise on a hill. In the distance of five miles there are only two places in which a team or car can turn around. It is either go ahead or back up.

In some instances the snow was soft and slushy and was four and as much as five feet deep. In others it had entirely melted, and the car was forced to make its way through from twelve to eighteen inches of water. In some places corduroy roads had been built through swamps and were now submerged in water, snow, and slush from a foot to three feet in depth. In no instances are these corduroy roads over sixty inches wide, and when one wheel went off the end it meant that it simply sunk out of sight and that the body of the car was resting on what was below; perhaps it was snow, perhaps water. At any rate, you could count on it resting on something that was not very good for your carbureter or your spark plug. In some places the snow was so deep that it was necessary to leave the car and dig roads through for the one wheel for which there was no passage before further progress could be made. One hill was encoun-

WORLD-FAMOUS LA ROSA MINE, WORTH \$20,000,000.

tered of about a 23 per cent. grade. It was not long, but down either side of it there simply ran rivers through which it was necessary to drive the car. There was absolutely nothing for the wheels to catch hold of. Whenever we would get the wheels ready to run the body would be on the bottom or ground so hard

WINCHING" THE CAR UP A VERY SLIPPERY HILL.

that it would have torn it all to pieces to have attempted to drive uphill. After about an hour see-sawing back and forth on the hill we gained the top by winching the car up with ropes wrapped around the rear hub and tied to trees ahead of us. In going down, although the brakes held the wheels till they slid, it required the most skillful driving to avoid a smash.

The arrival in Cobalt was "one grand entry." Our first call was paid to S. H. Logan, manager of the Canadian Bank of Commerce. He was very much surprised, indeed, to see anything move without horses tied to it in that section of the country, and expressed his surprise in quite strong language. Several hundred people immediately gathered about, inspecting the car from all sides. Our Cadillac was the first auto they had ever seen. It was decidedly the first car that had ever been seen in the entire Cobalt region.

Cobalt we found to be purely a mining town, different from

New Liskeard and Haileybury in that the houses had been thrown at greater random. The main street was something like twenty feet wide in its broadest places, and led into a public square. This square seemed to have been placed there by accident and left through force of circumstances. There are no saloons in Cobalt, yet one can buy anything in the way of refreshments that is desired. Law and order are maintained, but not a policeman can be seen anywhere. The one or two rich mines that have given the section its name for fabulous wealth are directly opposite the town of Cobalt, across the lake. One can stand on the porch of the Cobalt hotel, the leading hostelry there, and see the shafts of the famous Nipissing and La Rosa mines, can see the excavations of the Right of Way mines and Townsite mine, neither of which has thus far paid, and it seems as though will not pay; and you can but wonder why it is that there are some 2,000 people coming into this section each day, all to gain great wealth and returning without even their expense money in their pocketbooks.

So far as the automobile possibilities are concerned, in this section of the country there are none. During the Summer months, when the roads in the United States are dry and hard, teaming is abandoned in the Temiskaming district because the marsh is so deep and boggy that even liverymen plying between Haileybury, Cobalt and New Liskeard are compelled to take their loads down the railroad track, finding out at the different stations whether or not a train is coming, or will catch them before they can get to a switch, and either going ahead or waiting accordingly.

There has been, and continues to be, agitation for some sort of macadamized roads from Cobalt to Haileybury, which is the center of this region, but either the Provincial Government is opposed to it on account of its railroad, or else not enough pressure has been brought to bear as yet to secure them. The entire section is truly an enigma. It is an old country. You will find people who have lived here all their lives, but the country seems still new and is new and undeveloped. Its silver may be the richest in the world; what there is of it, perhaps, is, but geologists say that it is but a pocket and will soon be exhausted. If that time soon comes the \$300,000,000 of American and English money that is invested there will be sorely missed.

CROWDED CIRCUIT FOR GERMAN EMPEROR'S RACE

THE ninety-two cars entered for the German Emperor's Cup will be started on June 14 at intervals of one minute on a 74-mile circuit near Frankfort. The starting point will be on a plateau between Saalburg and Kloster Thron, about sixteen miles from Frankfort. Generally the road surface is excellent, and there are a number of straight stretches on which fantastic speeds may be attained; the passage through some of the towns,

however, necessitates a certain amount of caution, and there are a number of sharp turns which will test the skill of the drivers. There will be no neutralizations, and on the day of the race the course will be guarded by army veterans. To prevent accidents before the race minute regulations govern practicing. After a certain hour of the morning huge stones are rolled into the center of the road, making speeding impossible.

ROAD BETWEEN KONIGSTEIN AND OBERURSEL.

ENTERING THE VILLAGE OF WEILBURG.

DISMOUNTABLE RIMS AND THEIR USEFULNESS

ALTHOUGH dismantlable rims have given convincing proof of their usefulness and general efficiency as a racing adjunct, automobilists have been rather slow to adopt them, on the assumption that they were not suited for touring condition. Nobody denies the saving of time and labor in changing tires under the new conditions, but all motorists are not certain that the two metal surfaces will not rust and make dismantling an impossibility, or that the new conditions present the same degree of safety as the old. There are, in fact, several makes of dismantlable rims on the market which leave much to be desired in the matter of security. A very severe test of dismantlable rims was made by the 6,200-mile winter tour round Europe recently undertaken by Van Marcke as a try-out of a six-cylinder Hotchkiss car. The test provided all that the most exacting could demand: a fully equipped touring car, winter roads, long distance, mountain climbing, and fast running. Van Marcke's opinion is that the dismantlable rim gives all that can be desired of it. He has only one objection to bring against it. Each time he removed the metal valve cap to pass an inflated tire over the fixed rim a certain amount of air escaped from the valve, although he was certain when the tires were inflated that he had correctly screwed up the valve. Thus after putting the inflated tire in position on the wheel he had to pump a little air in to make up the amount lost.

A close examination of the wheel by Michelin experts revealed

the fact that the special type of metal cap used on dismantlable rims was responsible for a slight leak at the valve under road vibrations. On leaving off the cap no further trouble was experienced, and a rag wrapped round the valve protected it from dust. To prevent a recurrence of this trouble a sleeve has been designed to slip over the valve stem before the cap is put on.

Further lessons learned by the long tour were that the projecting end of the bolts should be wiped before taking off the nut. Unscrewing and screwing with dust and sand on the thread is bound to result in wearing down the thread and may be the cause some day of an unfortunate breakdown. Before mounting the nuts a rag should be passed through them and, as a further precaution, a drop of oil or a little grease should be put on the ends of the bolts.

For fixing the complete tire on the wheel a special brace is provided, which, to the surprise of many users, is not made to fit the special countersunk security bolts used on these rims. The reason for having two tools where one might be thought sufficient is that the safety bolts should not be screwed up tightly until the tire is completely inflated. It is the compressed air alone which should bring the bolt into proper position and not an exterior effort on the bolt. Thus instead of the brace, which is a powerful tool, and might be used injuriously, a special key with which a relatively small effort can be exerted, is used for the safety bolts.

"TROUBLES ON THE ROAD"

By A. D. HARD, M.D., MARSHALL, MINN.

MY little buckboard has been doing valiant service during the Winter months, when snow was deep and roads were almost considered impassable for anything on wheels. But I have not been exempt from "troubles on the road," and as there are many buckboards in use, it may be of interest to others to know how I emerged successfully from my perplexing predicaments. My first trouble came from the meddlesomeness of a "know-it-all" friend who undertook to increase the power of my motor by stretching the inlet valve spring. The result was that the suction of the piston was not sufficient to open the inlet valve except at high speed, and the motor could only be started by generously priming the cylinder with gasoline. The power was not increased. In my opinion, mechanically-operated inlet valves are the only proper kind, and meddlesome "know-it-alls" should be shot.

Most of the nuts on the buckboard are held in safety from shaking off by cotter pins, but some are not, and these began to work loose and drop off at most inconvenient times. All nuts that are vital to the running of an automobile should be crown nuts, with thin steel washers to adjust them so that the cotter pins would hold them secure from shaking off. The exposed position of the air intake resulted in snow and rain being drawn into the carbureter until the motor stopped. I tied my handkerchief over the intake loosely until I arrived home, then I placed a piece of rubber hose over the intake with the other end in a protected place, and had no further trouble. A ridge in the middle of the road struck the pan surrounding the transmission wheel, bending it up until it acted as a transmission brake. With my starting crank I pounded it down so that it would not touch the wheel, and at once got back my power. The screw which holds the chain together at the coupling dropped out and the chain came off. Borrowing a ten-penny wire nail from a nearby fence, I bent the surplus nail up over the chain so that it would not strike, and came home flying. A stone flew up and got caught between the chain and the sprocket wheel. Of

course the chain broke. With two quarter-inch bolts two inches long, found in my "catch-all-box," I bolted the chain together around the jackshaft sprocket, and also to a brace on the frame, and, putting the transmission on slow speed, came home at my usual speed with only one drive wheel kicking the ground.

My batteries gave out one cold night ten miles from home. I woke up a farmer, got some vinegar and, boring a small hole in the asphaltum covering of the cells with my jackknife, poured about one tablespoonful in each cell. I had a hot spark all the way home. When stalled in a deep snowdrift I tied a string to the switch in such a way that I could break the current with a pull while in the rear of the machine. Then starting the motor on slow speed, I got behind and pushed. I have got out of mud holes the same way. I broke a front wheel off in the knuckle. A telephone message brought me a livery rig from town, and with a halter strap I suspended the front end of the buckboard under the rear axle of the buggy, and the team came home on the trot, the buckboard following gaily on its hind wheels. Once I got in some soft ground so deep that the rear wheels sunk to the hubs and then slipped. I borrowed two fence boards from an obliging fence nearby and crowded them well under the drive wheel sprockets. The little machine crawled out on its sprockets beautifully. Ran out of gasoline eight miles from a supply at night. I worked my think-tank pretty hard for half an hour, then mixed four ounces of ether which was in my medicine case with one quart of kerosene oil from a farmer's lamp can, and, say, you should have seen that auto "hit the pike."

A leaking tire valve was most awfully persistent. I pumped up the tire and, detaching the pump tube from the pump but leaving it fast on the valve stem, bent it upon itself and tied it to a wheel spoke. On one occasion I lost my starting crank. Setting the transmission lever at high speed, I primed the cylinder generously with gasoline and gave the car a quick push of about three feet. The engine promptly began to do duty and I had to be quick to release the transmission.

THE ALBATROSS, AIRSHIP DESIGNED BY T. WEISS.

FLYING MACHINE MODELS AT LONDON SHOW.

LONDON, April 15.—There is a really pathetic side to the exhibition of flying machine models forming a part of the automobile show in the Agricultural Hall. One old man tramped thirty miles from a quiet little village in the west with his cherished model under his arm. You may talk with a score of them about the hall, earnest, serious-minded men, who for years have been groping along, unaided, neglected, isolated, but always confident that they were on the verge of one of the greatest discoveries the world has ever known. A mere glance at most of the models is sufficient to show that the designer has not mastered the elementary principles of aerial flight and that he has been working blindly, a victim of his isolation. Fortunately the models remain models; had they to grow into full-size machines they might have a decimating effect. There may be hidden somewhere in the hall a machine that can do more than make an aerial jump, but we have not discovered it. There are many that are curious, many that show ingenuity, and just as many that are crazy. One of the curious type is shown by Mr. Pickering, a native of the West Indies who has devoted forty years of his life to the evolution of his pet. It is on the compressed-air principle and consists of a drum-shaped body with small holes at top and bottom and four fans inside, which cause atmospheric action similar to that of a bellows. Under the machine is a powerful propeller driven by an electric motor, and around it are six circular tubes, slightly curved rearwards; the air is forced down these tubes, and as they slant back air is driven rearwards and the machine sent forward.

A Frenchman has a four-winged machine, worked by a strong spiral spring. Two of the wings go up while two go down, so that the air, by being forced away from the wings as they meet,

FELL AEROPLANE, EXHIBITED AT RECENT LONDON SHOW.

drives the model along. There is a weird looking creature with a fish-shaped body and two broad wings outstretched as in flight, all made of corrugated aluminum. The wings are made to flap by means of clockwork within the body, and in addition there are two propellers, one forward and one aft. Army officers play a considerable part in the exhibition. Major B. Baden-Powell has two or three rather promising models; Major Moore has two interesting models of winged-shaped flying machines mounted on miniature towers, with a double pair of wings, working one above the other in parallel. Captain Jones has an aeroplane which possesses more simplicity than can be found in most of the models. One designer has taken an albatross as his ideal, filled its body with machinery which gives a flapping motion to the wings. Another has worked on similar lines with a bat as his model. At the close of the show the models will be put through practical tests, but it is not likely there will be any startlingly practical results. The \$50,000 which the *Daily Mail* offers for a flight from London to Manchester will not change hands for a long time yet. A French aeroplane suggests the use of a small balloon with aeroplanes, as a measure of security in making experiments. To attempt a turn, an aeroplane must be some distance from the ground, and the failure of the engine at such a moment might be serious. A small balloon would prevent a violent fall, and its assistance in keeping the flying machine aloft would permit of observations of its actions being made and defects recognized.

LIGHT MOTOR FOR KNABENSHUE AIRSHIP.

TOLEDO, OHIO, April 22.—After a full winter's work, Roy Knabenshue has produced an original gas engine for his air ship. The motor, which develops from 12 to 16 horsepower, weighs only fifty-four pounds. It is of the two-cycle, air-cooled type, valveless, and will work with any carbureter. One of the features of the engine is a spark coil with six windings, instead of the usual primary and secondary. The carbureter throttle and spark timer are new features invented by Knabenshue, details of which have not been made public. The engine will be used for driving the steerable balloon on which Knabenshue has spent considerable time and labor.

PRESIDENT BISHOP HAS SAILED FOR EUROPE.

Cortlandt Field Bishop, president of the Aero Club of America, has sailed for Europe, and will remain abroad until September. Mr. Bishop intends to devote a large amount of time to automobile touring, particularly in the Alpine districts. In his absence the executive head of the club will be J. C. McCoy, who was recently elected vice-president.

AUTOMOBILE CHANGE GEARS AND THEIR JOURNALS*

By HENRY HESS, MEMBER SOCIETY AUTOMOBILE ENGINEERS.

FIG. 9 is a three-speed gear, with a three-gear slider. The slider spool is indicated by the shaft passing through it. The center distances of the shafts as well as those between the gears and bearings are to scale, each division of the cross-section paper representing one inch.

Each gear-pair is given a Roman numeral, as I, II, III.

The journal loads at the bearings for each drive are plotted vertically over each journal to a scale of one division equal 150 pounds.

Light arrow joints marked with the same Roman numerals show the amount of each load. Solid arrow points with numbers as 306, 307 give the rated steady load and speed-tabular capacity of the bearings known by corresponding number symbols.

A glance will show the relationship of imposed loads to bearing rating. In some cases bearing choice has been governed by shaft sizes and arrangement of parts rather than by loads, which accounts for some variations in selection. Occasionally the length of a load line would extend beyond the confines of the slide; it is then bent over and the true length is the total of the parallel portions.

"E" indicates the engine or driving end.

Considering the value of Fig. 9 we see that with the 26-26 tooth gear-pair I in engagement, the upper left-hand bearing

is loaded to the amount of arrow point I, which is about half the tabular steady load and speed capacity of bearing 306.

The load on the bearing at the other end of the upper shaft, due to this gear-pair, is very small, and indicated on the diagram as I at that bearing. On the lower shaft also the loads are well within the bearing ratings. The heavier loads on each journal are, counting from the top left to top right, to bottom left to bottom right, due to gear-pairs II, III, I and III. With one exception these approximate one-half the rated bearing capacity. The exception is the two-speed gear III load in the upper right-hand bearing, which somewhat exceeds the bearing rating. A similar condition is not unusual, as, for instance, on Figs. 11, 13, 16, etc. The conclusion must not be drawn that the other bearings are decidedly large, but rather that the relatively little use of this gear-pair, coupled with a slowing down of the engine and consequent reduction of actual piston pressure, favors this particular journal. Actual overloads to produce ball crushing are not to be expected of any bearing that is likely to be demanded by consideration of shaft size, etc.,

*Second part of paper read before Society of Automobile Engineers at New York; continued from issue of April 18.

remembering that bearings of the medium weight series are usual for gear boxes unless abnormally large bearings are demanded by peculiarities of the mechanism, in which case the light-weight series comes under consideration.

In the three-speed gear of Fig. 10, it is apparent that shaft dimensions have called for bearings having relatively larger factors as compared with the loads imposed.

FIG. 10.

The four-speed gear of Fig. 11 follows the previous Fig. 9, in that the bearing values are about double the loads with the exception of the slow-speed load that shows up higher than the bearing rating.

In the four-speed set of Fig. 12 all of the loads are well within the bearing capacities demanded by shaft diameters.

Fig. 13 is another example confirming the previous ones.

Fig. 14 has two sliding gear sets for four speeds. The bearings demanded by the shafts are all well above the loads, including even the slow-speed load. The fact that all bearings may be of the same size is a distinct shop advantage, not counter-balanced by higher first cost of bearings, since, even though a size smaller for one or the other might be worked in, the difference in cost of these smaller bearings is inconsiderable.

A first example of a direct drive jaw engaging gear with one slider is this Fig. 15. This is the first deviation from the general

FIG. 11.

FIG. 12.

FIG. 15.

practice of employing bearings of the medium weight series, two from the light-weight series, No. 207, carrying the engine and spool; their larger bore is demanded by the necessity for size due to the drive shaft being journaled in the spool. Approximately, bearings having the same outside diameter in the two series may be used interchangeably; thus bearing No. 305 used

the spool, and will be ample, as its location subjects it to smaller loads.

This succeeding example, Fig. 16, confirms the previous ones; as do also Figs. 17 and 18.

Fig. 19 is the first example of ball bearing use for the inner end of the drive shaft, where it is journaled in the engine shaft end. Rather restricted space consideration will naturally lead to the conclusion that this bearing (No. 305) would be relatively more heavily loaded, still, under the maximum condition due to gear set III—the second fastest—such load is within the bearing rating.

FIG. 13.

This is true also for Fig. 20. Here a comparatively small bearing of the light-weight series, No. 206, is quite ample for the outboard journal of the driving shaft—the upper left-hand one. If, however, any unbalanced couplings or other elements are carried near this, a bearing of corresponding bore of the medium-weight series, as No. 306, should be substituted.

As the spur gear part of Fig. 21 is along substantially the same lines as the previous examples, the bevel gearing only need be referred to. The thin direction arrows at the bearing below the bevel gear show that this is subject to radial load as well as the outward thrust of the gear, and also so mounted as to restrain the bevel gear against meshing too deeply. The magnitude of the thrust is measured from the shaft intersections to the arrowpoint. Remembering that one pound of thrust is the equivalent of three pounds radial load on a bearing of the radial type, an addition (not indicated) of four times the thrust length to the maximum radial load IV shows that the capacity of No. 207 is pretty well used up. Personally, I should prefer No. 307 to the 207 used in the German example.

on the other journals has an outside diameter of 72 mm., and a rating of 620 pounds as against No. 207, of 72 mm. and 600 pounds; but the larger bore of 35 mm. of 207, as compared with the 25 mm. of 305, adapts it for use on the spool.

No. 207 will probably work in best also on the farther end of

The thrust of the bevel pinion is taken on a collar bearing 6-R, which, as is shown by the arrow on the thrust line, has a factor rather better than two at the speed in question.

Figs. 22 and 23 are also bevel gear sets, in which the thrust bearings of the collar type have factors slightly less than 2 for Fig. 22, and about one and one-quarter for Fig. 23.

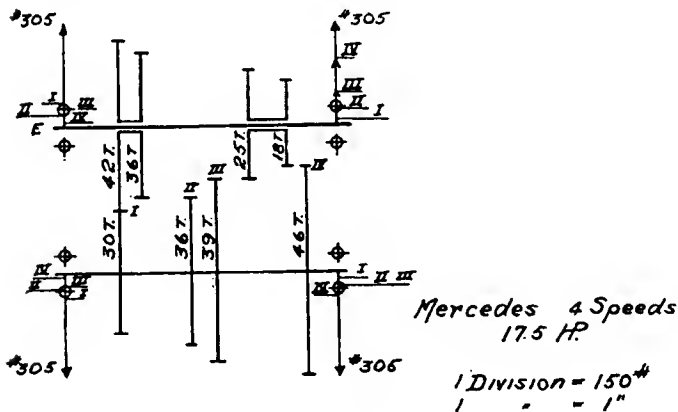

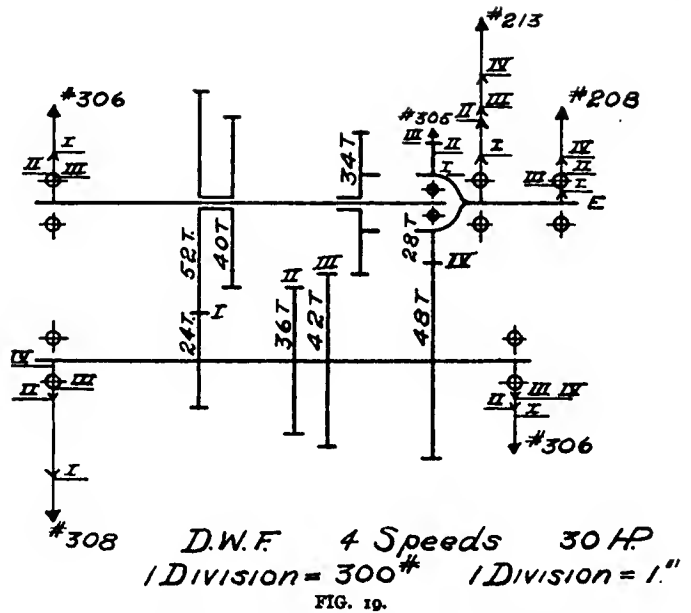

FIG. 14.

G. 16.

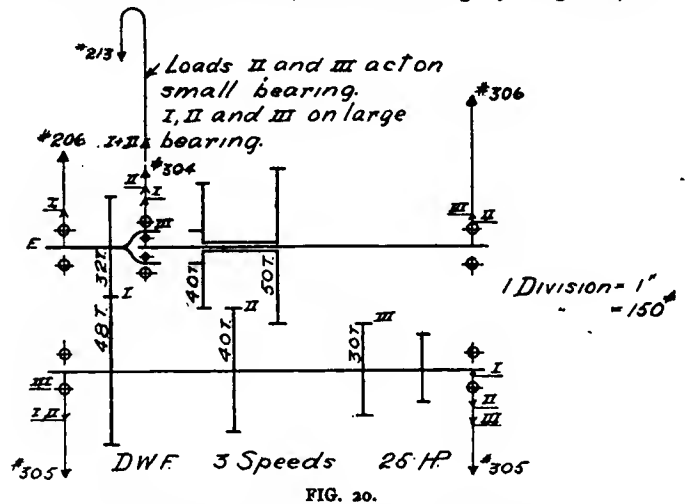

While similar records of experience may be collated for bearings of any type, whether ball, roller or plain, it must not be overlooked that this is a record of experience, and can therefore be applied, as regards sizes and all quantitative relations, only to the bearings in question, which were all either D.W.F. or H.B.

Similar records of actual experience with every form of ball or roller bearing in use have been carefully collated and the lessons drawn utilized along with these from the D.W.F. to aid my keeping up a steady advance in this highly specialized field.

The journal loads given in the various preceding examples are readily enough derived by calculation from a determination of the tooth pressure at each gear pair or torque at the gear radius required to transmit the H.P. at the speed in question, this in turn resolved into loads on the shafts at the centers of the gear faces in inverse proportion to the gear radii and these again divided between the shaft journals in inverse proportion to the distances from the journal center to the gears. Yet, a graphic determination of these factors has the advantage of simplicity of checking the intermediate steps, of proving the latter automatically, and of permitting the direct transference of the results with a pair of dividers to the journal diagrams.

In Fig. 24 one gear pair and the four journal locations of the two shafts are shown to scale. The pitch line torque L is laid off below to the desired scale; a vertical, M, corresponding to the gear radius, is laid off at one end of L upward, and the pinion radius N downward at the other end of L. A diagonal connecting the extremities of M and N will intersect L and divide it into two portions, P and Q, that give the loads at the shafts.

Taking the lever arm A of load Q to the journal, and erecting this as a perpendicular upward from the intersection of L just found, then dropping the lever arm B perpendicularly from the extremities of L, and connecting by diagonals, will

give intersections dividing load P into 1 and 2, acting on the bearings of the lower shafts and 3 and 4 acting on the bearings of the upper shafts.

If the torque L has been calculated correctly, all subsequent steps prove up, since the sum of the four loads must equal the original torque.

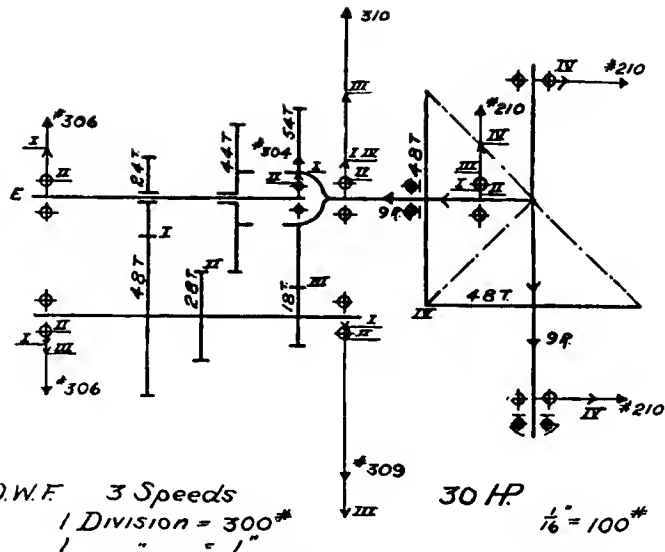

FIG. 22.

The graphic determination of radial and thrust loads is given in Fig. 25.

The calculated pitch line torque, L, is laid off to scale in a

FIG. 23.

direction normal to the pitch line. Lines parallel to the shaft are laid off from the extremities of L. From their intersection a perpendicular to L is drawn. From the meeting point parallels to the shaft are drawn. The resultants 1 and 2 are respectively the radial and thrust load of the pinion, and are transferred with the dividers to the gear diagram.

FIG. 24.

Distances 3 and 4 relate to the bevel gear respectively as thrust and radial load.

The thrust loads on the bearings are not affected by the location of the bearings along the shaft. The radial loads found act on the shafts at the point indicated by the largest pitch radii as shown. (Strictly, this is modified by the length of the gear teeth and their accuracy of contact. Theoretically, the correct point of average torque is about one-third of the tooth length inward. As all results are merely comparative,

FIG. 25.

this deviation from strict truth gives greater simplicity and does not alter comparative results.)

The division of these loads into radial loads acting on the journals is graphically accomplished in the same way as explained in connection with Fig. 24.

As there are present many users of ball bearings, and they no doubt will agree with me that their several interests can best be served by the fullest possible consideration of, not only their individual experience, but of that in connection with the experience of others, I sincerely trust that they will favor me with their observations, so that I may in future, as I have in the past, analyze and compare them and draw conclusions and make these available to all, though, of course, regarding the individual communications as confidential.

[EDITOR'S NOTE.—As the drawings are not reproduced here in the original sizes, the cross sectioning has necessarily been omitted.]

THE ADVANCE OF THE AUTOMOBILE.

The automobile industry having passed the perils of infancy and early youth, seems to be coming fast into its rightful inheritance as a prominent factor in the commerce of the country, says *Engineering*. Almost as soon as it was born it was attacked by that most terrible disease of young mechanical invention, the microbe of which is the company-monger. We remember with some satisfaction that we did what we could to counteract this danger, but its effect was so serious that for a long time the native industry was stunted in growth, and this country had to depend chiefly on imported cars for its supply. Another infantile ailment from which the motor car suffered was due to those owners of cars who used them simply for rushing along the highways of the country at the highest speed they could reach, regardless of the comfort, convenience, and even safety of all other users of the road. Shortcomings in design that marked the earlier stages of the movement we do not regard as morbid symptoms. Nothing mechanical is born perfect, and progress towards higher efficiency is always through experience; that which is abandoned on one day forming a stepping-stone for the more perfect device of the next. The steps, however, would have been fewer had the engineer been oftener consulted in early days. The trail of the unmechanical is still over the industry, but happily it is fast being obliterated.

SEEN IN GREAT BRITAIN'S SPRING SHOW

LONDON, April 13.—Cordingley's show, as the twelfth annual exhibition at the Agricultural Hall is generally designated, united about four hundred exhibitors, but had nevertheless quite a number of noticeably bald patches. Reo and Logan, the former with a pleasure car, the latter in the commercial vehicle section, maintained America's reputation for progressiveness. The Reo especially was a center of attraction, and the opinion was pretty generally expressed that its models would be hard to beat at the price. In a recent non-stop and flexibility run from London to Bexhill-on-Sea, a two-cylinder Reo made a very satisfactory performance, and placed itself high on the official list in a competition which distinctly favored powerful four and six-cylinder machines.

There are many here who fail to find a *raison d'être* for the independent show in the Agricultural Hall and would fain see the two exhibits united in one at the end of the year. Novelties are not expected here, for all firms from whom anything interesting is likely to come make a point of being ready for the winter exhibits. Its date, and the fact that there are always some firms behind time, give it ground for a continuance of its career. The man who is itching to exchange a handful of bank notes for a brand new automobile rushes enthusiastically to a show which opens its doors just as the winter frost is thawing out of the roads and spring breezes are calling to an open-air life. To the manufacturer who could not finish his models in time for the Olympia or the Paris exhibits, the spring friend is a friend indeed.

The exhibition is not representative of any one nation, for although England, France, Germany, America, Holland and Switzerland all have their representatives, not one of them shows more than a tithe of its products. The six-cylinder Spa, an Italian production, the Auto-Mixte and the Mercedes-Mixte, both gasoline petrol productions, the Nacke and the Horch are new to this country.

Some of the Leading Mechanical Features.

Among the aristocratic class of cars the new four and six-cylinder Spa machines, fresh from the Turin factory, attracted well-deserved attention. Standard European lines of construction are followed, cylinders being cast in pairs, valves on opposite sides, and induction pipe brought to a pocket common to each pair of cylinders in order to obtain equal fuel feed. The ignition is by low-tension magneto. Drive is by propeller shaft and live axle,

the torque rod and radius rods being of very substantial construction. Brakes, as is generally the case on high-grade Italian cars, are exceedingly powerful and are water-cooled and compensated. Those operated by the foot pedal are duplicated, one being on the clutch shaft and the other on the rear end of the gear shaft. Florentia, another Italian production, would enter in the same class as the machine just described. A six-cylinder chassis is exposed, with cylinders cast in pairs, valves on opposite sides, gear-driven Eiseman magneto on the induction side and

pump on the exhaust side, multiple disk clutch and four speeds and reverse. A very large inspection plate is provided on the gear box, equipped with a milled-head knob, a quarter turn of which will release the plate. The feature of the machine is the excellent rear suspension by three-quarter elliptic springs, and the diagonal frame stays at rear.

Novel features are found in the Porthos 24-32-horsepower chassis, with separately cast cylinders, valves on opposite sides and high-tension magneto. In addition to the fan behind the radiator the flywheel is vanned. Lubrication by means of a plunger pump sucking oil from a box on the dashboard and delivering it through a series of sight feeds is according to general practice, but is particularly ingenious in arrangement and design. The rearmost exhaust valve tappet rod is expanded near the top, so as to form a piston, the tappet guide being also broadened into a pump casing, with simple outlet and inlet ports, to which the oil pipes are connected; oil circulation thus must commence and cease

concurrently with the engine motion. The sight feed drips on the dashboard are jacketed by means of a by-pass off the water circulating pipes. There are entirely new features in the live axle. The differential shafts are split centrally in the usual manner and drive the wheels by dog clutches, but instead of the weight being carried on exterior sleeves, a solid rod completely passes from end to end through the differential and the hollow differential sleeves, and on this rod the road wheels are free to rotate. There is no exterior casing, the sleeves revolving in ball bearings suspended from three-quarter elliptic springs of ample dimensions.

Spyker, the well-known Dutch firm, has only made minor improvements to their excellent chassis. In the new model the dashboard is cleared of everything but a water gauge and a gasoline gauge, the dials of which are countersunk in the dash to

PRACTICAL DEMONSTRATION OF PALMER TIRE CONSTRUCTION.

DISTINCTIVE FEATURES OF REAR OF PORTHOS CHASSIS.

protect them from injury. There is an ingenious arrangement on this car by which the leather-faced cone clutch can be disengaged with the minimum of exertion. A cross-bar level with the clutch shaft, with the end hinged to the side of the main frame, gives a very powerful leverage and enables the clutch to be withdrawn instantly by a touch of the toe.

There is a newcomer to this country in the Horch car, produced in Saxony. It has four-cylinder engine, cylinders cast in pairs; valves all on one side with overhead inlets having large bearings to the rockers. Ball bearings are employed for both camshaft and crankshaft. There is an original feature in the gasoline supply. The main tank at the rear is under pressure and feeds a small tank on the dashboard holding nearly a pint of gasoline. From this tank the fuel flows by gravity to the carbureter. The advantage is that there is always a quantity of fuel available for starting without pumping. There is a double universal joint between the clutch shaft and the gear box; the latter is of the double sliding type with an extra ball bearing on the direct drive shaft, so that no part of the divided shaft is unsupported. When the top gear is engaged the lay shaft is idle, the cardan shaft being in a casing hung in one line with the ends of the radius rod, hence the casing acts as a torque rod.

Useful Minor Improvements Are Numerous.

Among the improvements in detail, more numerous than changes in structural parts, there is on the Adler car a concealed trigger, covered by a hinged cap in the top of the change speed lever to prevent reverse being used unintentionally. Before reverse can be put in the cover must be raised and the trigger depressed. With this arrangement it is almost impossible to put the reverse in accidentally. The brakes are water-cooled and to obtain a flow of water all that is necessary is to depress a

POWERFUL WATER-COOLED BRAKES OF S. P. A. MACHINE.

small toe pedal pivoted to the bracket of the foot brake pedal. The distinctive features of the Horseshoe car is a radiator in the form of a horseshoe. There is nothing to be said about the engine, but the type of the radiator gives the car a distinctive feature. On the Metallurgique, a Belgian machine, there is an oil splash guard above the flywheel. On the Unic car (Georges Richard) the oil reservoir to supply the sight feeds on the dash is carried inside the bonnet, thus maintaining the oil in a fluid condition in cold weather. On the Peugeot car a drain tap is fitted in the base of the gear box.

Petrol-gasoline vehicles were the feature of the exhibits in the heavy section. None of them are entirely new, though the Auto-Mixte and the Mercedes gasoline-petrol chassis are sufficiently novel to attract considerable attention. The principal features of the Auto-Mixte, a Belgian production, are the use of a dynamometer, an electro-magnetic clutch, a compact set of accumulators and an electrically controlled carbureter. Braking is also electric. Omnibuses are particularly prominent, for the Britisher has implicit faith in this vehicle to solve the transportation problem in great cities. There are more examples of the commercial vehicle for passenger service than for transporting goods.

What the Accessories Section Offers.

The inventive genius gives his fancy full play on the thousand and one accessories, which, though not forming a fundamental part of the car, would leave the automobile in a very pitiable condition if they were withdrawn. A few of them were good; the majority were of doubtful utility. In the former class can unhesitatingly be placed the Ripault combination valve grinder and remover. The tool, which is of French origin, has already been described in *THE AUTOMOBILE*. It is a simple kind of brace which compresses the valve spring and allows the valve to be withdrawn without difficulty. For grinding valves a screwdriver blade is slipped into the brace. The same agent shows a ratchet which enables the jaws of the spanner to be set at any desired angle to reach nuts in awkward positions. There is an excellent

NEW TYPE VALVE; CONNECTOR.

idea in a universal tire valve connector which has simply to be placed over the valve, requires no screwing, cannot come off when pumping, does not leak and fits any size valve. This little device was exhibited two years ago by a French mechanic in an unpretentious inventors' exhibition in Paris, but this is, we believe, the first time it has been offered to the public. It consists of a cup-shaped metal vessel surmounted by tube *D*, to which is attached the rubber tube connected with the pump. The base of the cup is closed by the piece *E*, of best quality rubber, held in position by plate *C*, fixed in place by the nut *B*. The rubber washer *F* has a hole in its center through which passes the valve. The cup-shaped terminal being placed over the valve, the rush of air presses the part *F* of the washer on the valves and prevents any leak. As is self-evident, the greater the air pressure the more firmly will the washer be pressed on the valve.

Among the speed and distance recorders is an interesting instrument shown by the Cowley Engineering Company. In addition to the ordinary speed and distance marking, there is a dial on which is recorded the speed maintained during the preceding half-mile. This serves as very useful evidence in unjust police proceedings. The record is traced by white pins, which take up their position in segmental slots in the black center dial. The apparatus is worked positively, by the usual type of linked chain.

S. Smith & Sons, of speedometer fame, have a big show of their specialties, among which may be mentioned a combination compass, barometer, speedometer and clock. The barometer, speedometer and clock are in one line on a polished board and the compass is suspended in a circle above them. There is a

well-designed folding canvas bucket with handle and lip complete, shown by the French Motor Accessories Company. The Stepney spare wheel has been before the public long enough not to be classed as a novelty. An improved type is, however, shown for the first time. The spare wheel clips onto the rim and is held there securely, while leather straps round the spokes prevent creeping. The new type is adjustable to fit any size wheel. When a puncture occurs the Stepney wheel is placed in position, an operation of three or four minutes, the punctured tire is left in its place and the journey finished with the makeshift.

The popular exhibit in the accessories section is the Palmer Tire Company's new automatic machine for making Palmer cord tires. As will be seen from illustration, the tires are made of layers of rubbered cord. It is claimed that the triple grooved pattern will not skid until the tread is worn and that the tread can be remade at little cost. The distinctive feature of the Vivian non-skid tire is that it is composed of alternating sections of hard and soft rubber. Elastes occupies a rather prominent position in the exhibition, though it cannot now claim to be a novelty; it may, however, be new to home readers. Instead of an air chamber, the outer shoe envelops a roll of composition composed of gelatine, glycerine and chromate salts, made to any consistency to suit cars of various weights. The composition bears a very close resemblance to the material used for making printers' rollers. Punctures are of course impossible and there is not any noticeable alteration in the resiliency of the tire. The makers declare that it prolongs the life of the outer shoe. America's share in the accessories section is the Rushmore lamp and a number of lubricating oils shown by British agents. Rushmore, who is as well known here as over the water, had as an attraction a large naval searchlight projector, working on the same principle as the smaller automobile searchlights.

LONDON-PARIS WEEKLY AUTO SERVICE.

LONDON, April 13.—In a few days Londoners will be able to visit Paris in a much more agreeable manner than by the Southern British and Northern French railroad routes. Starting on May 3 there will be a regular weekly automobile service between the two capitals by means of a 50-horsepower Gobron Brillie touring car. The automobile, with five passengers on board, will start from the Carlton Hotel at 8 A. M., call at the Ritz, in Picadilly, fifteen minutes later, and proceed by way of Maidstone to Folkestone, arriving in time for the 11:30 boat, reaching Boulogne at 1:30. The machine will immediately proceed for Paris by way of Abbeville, Grand Villiers, Beauvais, and Pontoise, reaching the Ritz Hotel about 8 o'clock. After a week-end in the gay capital, the party will leave for London on Monday morning, arriving same evening.

EIGHT-CYLINDER ENGINE PRODUCED BY ALL BRITISH COMPANY.

NOVEL BRITISH EIGHT-CYLINDER ENGINE,

LONDON, April 13.—As a mechanical novelty there was nothing in the Agricultural Hall show quite so interesting as the eight-cylinder engine built by the All British Company. The illustration given herewith furnishes a good idea of how the huge machine looks. The purpose for which it is to be used was not disclosed. It is not a stationary engine, it is too big for a car and it is far removed from the general marine type. It will be noticed that the cylinders, which are cast in pairs, are in two lines, with the crankshaft centered between them in an exceptionally deep crankcase. Instead of the usual connection with the crankshaft by means of a connecting rod, the connection on this engine is by means of rocker arms and connecting rods, as employed on the Arrol-Johnston machines. Valves are all mechanically operated, the inlet valves being in the heads, operated by rocker arms, and the exhaust valves in pockets on the sides. The throttle control is a distinct departure from standard practice. It consists of a system of cams by which the driver is able to entirely cut out of operation one, two or more cylinders, according as he desires to reduce power, the remaining cylinders always working with a full charge and constant compression, and therefore under the most favorable conditions for economy. Ignition is by high-tension magneto mounted on a bracket to the rear of the engine and above the top of the crankcase. Very large inspection plates are provided on the sides of the crankcase.

SIX-CYLINDER FLORENTIA CHASSIS, ONE OF THE ITALIAN MASTERPIECES AT THE LONDON SHOW.

LETTERS INTERESTING AND INSTRUCTIVE

Regarding Intake Leads and Their Equalization.

Editor THE AUTOMOBILE:

[715.]—I am designing a six-cylinder automobile engine, and find myself at a loss in reference to the arrangement of the intake piping. I want to get the distance from each cylinder to the carbureter as nearly equal as possible, so that all of the cylinders will develop the same power. I also want the leads to be as short as possible, so that there will not be any considerable volumes of mixture between the carbureter and the cylinders, to attenuate when the engine is speeded. Is it possible so to equalize the intakes of a six-cylinder engine that they will feed the cylinders as evenly as can be done with a four or eight-cylinder engine? What do you think of the advisability of using more than one carbureter on an engine of the sort I have in mind?

A. R. W.

Pontiac, Mich.

If you mean that you require an intake piping of perfectly symmetrical form, such as the single, double and triple Y's used for four and eight-cylinder engines, we can say at once that nothing of the sort is possible. Very good approximations are secured, however, in feeding the fuel to most six-cylinder engines by arrangements that compensate for differences in distance and directness of fuel flow. You will find many interesting examples among the best modern six-cylinder machines, which it will repay you to study. The distance from a carbureter to the cylinder or cylinders at feeds always should be as short as possible, because of the effect you mention. But it is, of course, impossible to secure very remarkable results in this respect with a six-cylinder engine fed by a single carbureter, and it probably is a fact that few multi-cylinder engines develop the same power in each cylinder. The use of a plurality of carbureters, though it has been suggested by at least one exceedingly prominent European designer and builder of cars, is open to the objection that it is practically impossible to adjust even two similar carbureters alike, so the unequal feeding of different cylinders by no means is done away with by this scheme.

The Position of the Spark Plug.

Editor THE AUTOMOBILE:

[716.]—If it is not too much of a demand upon your space, I wish you would let me know through your columns what is considered the best point in the cylinder for the spark plug. That is, should it be located exactly in the center of the combustion space, or is it all right to have it to one side, as is the case in so many cars? Is it really an important advantage to ignite the charge in the middle, so as to get it consumed in the quickest time possible?

Milktown, N. J.

ARTHUR BEVERIDGE.

A very little study of modern automobiles will convince you that there is no agreement, among those best qualified to judge, as to the best position for the spark plugs. Some makers place them in the centers of the cylinder heads, others place them over the inlet valves, others still place them in the sides of the cylinders, and a few prefer to locate them by the exhaust valves. It is on purely theoretical grounds that the center of the combustion space is held to be the correct location for the ignition to start from. Practically, no such great advantages as this argument assumes are shown to exist, since the rate of flame propagation in an explosive mixture of the sort used in an automobile is in the neighborhood of 3,500 feet a second against a piston speed of not over 1,500 feet a minute. The result is that no matter where ignition is commenced, the combustion is sure to be accomplished quickly enough for any practical purpose. You will find that most automobile designers who place the spark plug in the center of the cylinder head do it primarily for other reasons than the one you seem to regard as most important. For instance, the reason usually given for placing the plug over the inlet valve is that, in this case, when the spark occurs, it is more likely to be in fresh mixture than if at some other point, where retained exhaust gases might be pocketed. The argument for the exhaust valve placing is the scouring action of the hot gases.

A Query Concerning the Proper Mixture.

Editor THE AUTOMOBILE:

[717.]—Under the head of Letters Interesting and Instructive, will you kindly let me know about the following?

On a two-cylinder, 20-horsepower car I occasionally shut off the gasoline supply at the tank, when in the barn after a run, and allow the motor to run until the carbureter empties itself with the motor running. I notice that just before the supply is exhausted the engine speeds up very materially, increasing its revolutions per minute considerably, although the spark advance lever remains at the same position—the effect is the same as if the spark were greatly advanced. Does this indicate that I am using too rich a mixture while on the road?

(2) Theoretically, should a richer or thinner mixture be used in hot weather as compared with cold weather, assuming the humidity to be the same?

(3) Does the theoretical answer to the last question hold good in actual use and practice?

MIXTURE.

Walden, N. Y.

As you surmise, this action of the engine would undoubtedly seem to be due to the better-proportioned mixture created when the fuel is just about to give out. Your running the motor in this fashion, *i. e.*, allowing it to empty the carbureter after the gasoline supply has been cut off, also serves to disprove some of the many fallacies regarding the necessity of minute adjustment of the gasoline level in the float chamber. We should say that this action did indicate the fact that you were using too much gasoline under ordinary circumstances, but when running on the last drops of fuel in this manner the engine will at a certain point be receiving a theoretically perfect mixture, which will be difficult to more than approximate by carbureter adjustment. Further, the engine will continue to run for a short time on a mixture far too weak for starting or ordinary running, as it is running light and everything is hot—conditions conducive to the use of a very weak mixture, so that it will not pay to attempt to get the carbureter adjustment too fine.

(2) As it is possible to run the engine on a far weaker mixture than is ordinarily available, when everything is hot, and as the engine naturally tends to run hotter during warm weather, we should say that the use of a weaker mixture in summer was in conformity with theory in this regard.

(3) In a certain sense, it does. That is, with stationary engines like the Deutz and the Diesel, using an extremely high compression the weakest possible mixtures are used, demonstrating that the high temperature will satisfactorily burn a mixture that otherwise would not ignite. These engines are about the most economical in fuel consumption that have ever been built. Concerning the automobile alone, however, we doubt if many autoists find that a distinctly different carbureter adjustment is needed in warm weather as compared with cold. On the other hand, it is a matter of common knowledge that the average driver runs his car on a mixture that is more or less too rich in gasoline, and frequently very much too rich. The latitude of adjustment under which the engine will function satisfactorily is accountable for this.

Distribution of Water in Radiators.

Editor THE AUTOMOBILE:

[718.]—I have a water-cooled car, built two years ago, which is causing me considerable trouble by overheating when the weather is the least bit warm. I have examined all of the usual causes of such a difficulty, but the only thing I can find wrong is the radiator, which becomes hot at the center, while remaining cool at the sides, whenever the motor is run for a while. The radiator is of the vertical wavy-tube type, resembling a honeycomb in its general appearance. I do not know whether it used to vary in temperature as it does now because I never examined it before for any similar trouble, but I do know definitely that something is wrong, for with exactly the same fittings and under similar conditions the car used to run all right. Should there not be some sort of baffle plates in the top of the radiator, to distribute the in-

flowing water in such a way that it will not run right down the nearest tubes? I have an idea that there once were such baffle plates, but that they may have been corroded out or through by an anti-freezing solution I used last winter. I do not think that the radiator tubing is obstructed, because the flow of water through the cooling system seems quite unimpeded, which I imagine would not be the case were there deposits clogging the tubes.

St. Louis, Mo.

DR. LEONARD DECKER.

It looks as though at least part of your troubles were due to some obstruction in the tubing, whether there are damaged baffle plates or not. It is not disproof of this that the water seems to flow freely, for the water space in a radiator of the type you describe is much greater than the cross-section of the piping used in the cooling system. In some early cars not enough attention was paid to the distribution of the water into the radiator, and it is possible that the design of your car may need some correction in this particular. The water should enter, of course, at the top of the radiator, so that it will flow down as it cools. From the main intake there should be separate internal channels to divide the stream and conduct its parts each to a particular group of the cooling tubes. If all this is lacking it will hardly be possible to supply it except by sending the radiator to the manufacturer for the required alterations, for assembling and soldering a radiator is an exceedingly difficult job, scarcely to be tackled except by an expert. To remove any corrosion that may be present, fill the radiator with a caustic-potash solution or a ten-per-cent. solution of sulphuric acid in water. Both of these are powerfully corrosive, so must be handled with caution and not left in the radiator too long. After draining them out repeated rinsings with clean water should follow.

How to Charge Accumulators from Gravity Cells.

Editor THE AUTOMOBILE:

[719.]—Can you or your readers give me any data or directions in regard to charging a six-volt storage battery from gravity cells such as are used in telegraph work? I understand this is done in Europe, but have not heard of its being used in this country. Any information you can give me will be greatly appreciated.

W. J. C.

Aqueduct, N. Y.

Charging accumulators by means of gravity cells can be done without any difficulty, but is a rather slow and somewhat expensive process. The gravity cell only has an output of .4 to .5 ampere at .9 to 1 volt potential. As your six-volt set of accumulators is probably either of 40 or 60 ampere hour capacity, it will be readily apparent that quite a few cells of gravity battery will be required if the charge is to proceed at a reasonable rate. While under charge and approaching saturation the storage cell reaches a voltage of 2.5 or slightly over, so that in order to be on the safe side at least 10 cells of gravity battery would have to be connected in series. The current available would then be .5 ampere at approximately 10 volts; if your accumulator is of 40 ampere capacity it would require 80 hours or more to charge it, and if of 60 ampere hour capacity 120 hours or over—in other words, the better part of a week in the latter case. The time can be shortened by providing another set of ten gravity cells connected in series and the two sets connected in multiple, the available output then being one ampere at ten volts, which would cut the length of time required for charging approximately in half.

The cells should be of the 6 by 8-inch size and they must be placed on a solid foundation where they will not be subject to even slight disturbance, as this will interfere with their working. Unfold the copper strips in star shape, place in the jars and cover with about three inches of water, then pour in three to four pounds of sulphate of copper (bluestone); hang the zinc from the edge of the jar and fill with water to within an inch of the top. To render the cells active without delay, five ounces of sulphate of zinc should be added to each and the whole battery placed on short circuit—i. e., connect copper terminal of one end cell to zinc of opposite end; a teaspoonful of sulphuric acid per cell may be employed in place of the sulphate of zinc. As soon as the cell is working satisfactorily the separating point of the

two solutions will be clearly defined, the upper being colorless and the lower a deep blue. At least twenty-four hours on short circuit will be required before the cells give their normal output; the cells should never be disturbed. To keep the cells up to maximum efficiency they should be tested with a hydrometer every week or two; the upper solution should allow the instrument to sink to 25; if heavier, draw some off and add clear water until this point is reached. If the zinc becomes badly coated it must be lifted out and scraped and washed; fresh bluestone should be added as needed by dropping in carefully a little at a time. Trouble arising from evaporation, dust and creeping of the salts may be prevented by pouring about half an inch of heavy paraffine oil on the top of each cell.

Remedying One Evil Apt to Bring On Another.

Editor THE AUTOMOBILE:

[720.]—I note in your issue of April 4, letter No. 681, in which Mr. MacArthur suggests a method for preventing carbonizing of a motor. Doubtless Mr. MacArthur's method will prevent carbonization, but I think there is a great drawback to this method. If you should raise a cylinder one-quarter inch as is suggested, it would greatly decrease the compression of the motor. For example, take a motor with a bore and stroke of four inches. Take the compression space as 30 per cent. of the volume displaced by the piston, which will be 15.08 cubic inches. Now, if the cylinder is raised one-quarter inch it will increase the compression space 3.14 cubic inches. Adding this to the former compression space we have a total of 18.22 cubic inches. Assuming the compression to be about 66 pounds for 15.08 cubic inches, it will decrease proportionately for 18.22 cubic inches. Therefore,

18.22:15.08::66:55.

Then, the difference between 66 (the compression at first) and 55 (the compression after raising the cylinder one-quarter inch) is 11 pounds, which I should think would cause considerable loss of power.

I think if anyone were to try this method it would be advisable to fasten a metal plate, equal in volume to that gained by raising the cylinder, to the cylinder head.

HOWARD EDDY.

Hartford, Conn.

We presume the evident intention of our correspondent, Mr. MacArthur, was mainly to point out to the designer the error of his ways in this respect, and to recommend that the engine be so constructed that the piston should not rise into the counterbored space in the combustion chamber, which, of course, would be the best preventive. That the expedient of raising the cylinders of an engine already in use, which he suggested as a cure, will result in the evil you speak of, goes without saying. Of course, it can be overcome by the insertion of a metal plate in the head, of a thickness equivalent to the difference caused by the elevation from the crank-case, but it strikes us that this is an extremely laborious method of beating the devil round the bush, merely to overcome what ought to be preventable by far simpler and less expensive means. With the proper quantity and quality of lubricating oil and the proper fuel mixture, it certainly should not be necessary to dismantle an engine more than once a season—and that at the end, on this account. The fact that there are thousands of gasoline engines of the stationary type that run 10 to 12 hours a day and six days a week, most of the time under full load, without suffering from this cause, shows that the average autoist still has a great deal to learn on this score.

Some Queries Regarding Proper Lubrication.

Editor THE AUTOMOBILE:

[721.]—Please answer these questions in the columns of your valuable paper: (1) What is the best method of determining the proper amount of cylinder oil to feed cylinders of two-cylinder-opposed motor? (2) Am at present using light Monogram. Under the same conditions, should I feed more light oil than medium? (3) Should I feed less oil to rear cylinder than front, and why?

Kingston, N. Y.

JAY TERRY.

It is difficult to lay down a general rule for determining the amount of oil to be fed to a motor when the only data given is that it is of the two-cylinder opposed type. The power and speed at which it runs are both important, as well as the manner of cooling, air-cooled motors requiring more oil of a higher fire test

than water-cooled motors. It is customary for manufacturers to state in their instructions accompanying the car, just how many drops per minute should be fed from the different cups. Failing this, they should be adjusted to deliver just sufficient to keep the various parts of the motor well-lubricated; in the case of the connecting rods and pistons, this may be determined by setting them at a certain point—10 to 15 drops per minute should come near the correct quantity in your case, as the double-opposed type of motor usually runs at a comparatively low speed, and noting the effect. Should this quantity prove excessive, the result will soon be noticeable at the exhaust, as the surplus will burn in the cylinders and produce a bad deposit of carbon unless corrected. In order to determine whether it is sufficient or not, clean out the crank-case, fill with fresh oil to proper level, which should be just so that big-ends dip in it about half an inch on the lower part of their sweep, set the feed as already mentioned, and at the end of two or three hours running—not long enough to endanger the motor should the feed be insufficient—inspect the crank-case interior again and note whether the amount has unduly diminished or increased. In this way, it should not be difficult to ascertain just how much oil is required to keep the interior of the motor properly lubricated. In the case of out-board bearings, the condition in which they run will be indicative of their lack or excess of oil; the makers usually provide oil or grease cups of a capacity calculated to last each particular bearing a certain length of time, and if they are kept filled, there is little to fear from hot bearings.

2.—The amount of oil necessary will naturally differ with the quality, but if the light oil you speak of is better adapted to the purpose than what you were previously using, it will probably require less rather than more of it.

3.—We cannot conceive of any reason why the rear cylinder should receive less oil than the front, unless the engine does not happen to be levelled on the chassis and the oil tends to flow toward the rear cylinder at all times. Under normal conditions, both cylinders should receive the same amount of oil.

How Some Cars Dispense with the Differential.

Editor THE AUTOMOBILE:

[722.]—Will you kindly enlighten me as to the following through the columns of your valuable magazine:

In your April 11 issue I read an article regarding this year's Grand Prix to be run in France next summer, and I notice that the Darracq and Renault racing cars are being built without differential. Will you kindly state how this can be possible.

New York.

DAVID F. LADIN.

The three Darracqs, the three Renaults and the Christie racer in the French Grand Prix are without differential. The American machine with its front drive is, of course, in a class by itself, but the two other makers follow established custom excepting that they have cut out the differential. Drive in each case is by propeller shaft and bevel gears to one-piece rear axle; the only difference between the racers and the touring cars of these makers is that the axle is undivided by a differential. A saving of weight is obtained by suppressing this organ, but the chief advantage, the makers declare, is that the rear wheels hold to the road better. The Renault racer with which Szisz won the Grand Prix last year and the Darracq machine with which Wagner captured the Vanderbilt Cup were both minus a differential.

EXPLAINING THE ACETYLENE MYSTERY.

Editor THE AUTOMOBILE:

[723.]—In your "Letters Interesting and Instructive" department, in the issue of "The Automobile" of March 14 last, I particularly note letter from B. A. Birtiss (Number 636), descriptive of his experience with explosions in copper tubes connecting acetylene with lamps.

I beg leave to suggest that copper acetylide is a very dangerous and highly explosive fulminate formed by the combination of the acetylide of copper and oxide, the explosion being due to the effect of bending the pipe the same as would be the case in the presence of dynamite. I should also beg leave to suggest that an article by some chemist familiar with this matter would be a most excellent one for publication in "The Automobile."

As the formation of copper acetylide and subsequent dangerous explosions thereof are an ever-present possibility with acetylene generators, conducting pipes and lamps as now used on automobiles, possibly the makers of acetylene gas generators may be able to offer some suggestions as to the prevention of difficulties of this kind.

ADVANTAGES OF MAGNETIC GASOLINE GAUGES.

Editor THE AUTOMOBILE:

[724.]—An article in the "Horseless Age," under date of April 10, under the heading "A Suggestion for Maintaining a Reserve Supply of Gasoline," while instructive to novices in automobiling and motor boating, is hardly up to the time, and puts one in mind of the dog barking up the tree after the coon has left.

There was a time, but in the dim past, when articles advising as to the particular class of wood and shape of stick to be selected for measuring gasoline in a tank, and articles advising motorists to carry along an extra jug which, while never taking up any room always managed to be in the way and constituted an eye-sore, and also suggestions as to reserve tanks, may have constituted interesting reading. If the writer may make a suggestion, it would be that many wise people have learned that the installment on the tank of a magnetic gauge such as the Triumph, used by Pierce-Arrow, Matheson, Knox, Stearns, Northern, L. S. Ross, Marmon, Moline, and other high class cars, and by the S. F. Bowser Company on their gasoline storage outfits, represents the advanced line in taking care, in a practical way, of the gasoline supply. The stick which many use invariably introduces dirt in the gasoline, and the evaporation of the gasoline from the stick frequently requires a chaser to find the gasoline mark on the stick. So, too, the reserve tank may be compared to an old-fashioned engineer who suggested a device to operate a whistle that the brakemen might apply the brakes and stop the train, thereby notifying the engineer that water was actually needed in the locomotive boiler, and in this case the stop would be made irrespective of the location of the water supply. An Eastern man might consider the stopping scheme suitable for the B. & A. road, but a modern engineer prefers a reliable gauge, a glance at which will show the water conditions long prior to an emergency, and not necessitate a stop.

If a gauge is necessary on a locomotive boiler, certainly a reliable tank gauge is a practical necessity on the gasoline tank of an automobile, not only for the comfort and convenience of the user of the car, but because a glance at the head of the gauge will render it unnecessary to stop the car when in doubt as to the quantity of gasoline to complete a run. It appears to the writer from his own experience, that too much cannot be said in favor of the installment on every gasoline tank of a reliable magnetic gauge, and further, the use of such a gauge results in lessening the amount of money paid for gasoline when touring, as it acts as a faithful bookkeeper.

C. E. C.

Boston, Mass.

FROM THE BRASIER REPRESENTATIVE.

Editor THE AUTOMOBILE:

[725.]—A clipping has been sent to me, by the Brasier firm, which appeared in your paper March 21, page 532, under the head of "Gustave Chedru Joins Thomas Company." Mr. Brasier states that the information which you have in this article is wholly and absolutely incorrect, in so far as Mr. Chedru's connection with the firm is concerned. Mr. Brasier states that Mr. Chedru at no time was chief engineer, and at no time was chief designer, or at no time held any principal place in the Brasier factory; and he further states that Mr. Chedru never designed or had any principal part in the design of any Brasier racing machines.

Mr. Brasier further states that Mr. Chedru stayed with the Clement-Bayard people for three weeks, and this was his total connection with that firm. That as to his being chief engineer in the Brasier firm, his position was simply that of draftsman, and that his work comprised nothing further than the carrying out of explicit instructions.

I would be very glad, in view of the above, if you would give sufficient prominence to Mr. Brasier's statement herein contained, as it is wholly unfair and unjustifiable that this man should be sailing on the laurels of the Brasier firm and be credited for work which he has never done.

It is all very well to damn the French car, and state how fine the American car is, and there is no question that a good many of the American cars are really good, but it is absolutely wrong, in my estimation, to steal any man's thunder and to take one of the best machines in the world and try to build up the reputation of an American machine on the already made reputation of a high-class foreign car. I kept still during the last campaign of free advertising on the Brasier reputation, but I do not propose, at the present time, to keep quiet any longer.

E. B. GALLAHER.

New York City.

DOING AWAY WITH THE DUST NUISANCE.

Any preparation which will remove the dust nuisance will be heartily welcomed by the automobilist. But to be generally adopted such preparation must be cheap, easily applied, lasting, have no injurious effects on tires, nor be harmful to the eyes. Rather more than a year ago a coal tar preparation known as Tarvia was introduced to the public and has since been used on more than 800,000 square yards of road with very satisfactory results. The roads were located in thirty different cities in various parts of the country and some of the work was done in Jackson, Tenn., under government supervision.

Tarvia is a coal tar preparation which can be applied to the surface of a macadam road in such a way as to unite the top dressing into a waterproof bonded surface which will not disintegrate into dust. The method of treatment is as follows:

First, the road to be treated should be a well built, firmly bonded macadam in fairly smooth condition. If the road to be treated is a new one, it should be built in the usual manner, and, after the road is puddled, sufficient screenings spread over the surface to protect it against raveling by the traffic; allow the traffic to use for two to six weeks or until the road is thoroughly dried out, when the screenings which are not bonded should be removed, leaving exposed the inch or inch and a half stone which forms the wearing surface.

If it is an old road which is being treated, all screenings, dirt, etc., which are over the inch or inch and a half stone, whichever is used for the wearing surface, shall be removed, either by sweeping, or by scraping if the screenings are caked. Many roads are maintained by keeping from 1-2 to 1 1-2 inches of screenings which have passed a quarter or half-inch mesh caked on the surface by continually wetting and rolling, and it is absolutely necessary that these should be removed in order to make a satisfactory job. If they are not removed, the result is that as soon as these screenings are dry the adhesion is destroyed and the screenings become entirely loose, thus breaking the entire tarviated surface; consequently they must be removed, even if necessary to scrape. After the macadam is thoroughly cleaned and perfectly dry, it is coated evenly with Tarvia heated to a temperature of from 160 to 180 degrees Fahrenheit, using from 1-3 to 1-2 gallon per square yard. Various methods of heating have been used, namely, tank wagons holding from 500 to 600 gallons, with fire boxes, roofing kettles mounted on wheels, and in many places the work has been convenient to the factories, so that the preparation is delivered hot direct from the factory and no heating is required.

Sprinklers for distributing from the tank wagons, made with pipes with slots and small holes, have been used in the hopes of doing away with the sweeping, but so far nothing of the kind has given sufficiently even distribution. The most satisfactory method has been to use a hose attached to either the tank wagon or the roofing kettle, allowing the Tarvia to flow from the open end onto the road, and sweeping with street sweepers' fiber brooms.

After the Tarvia has been allowed to penetrate the road for from two to twelve hours, it is covered with an even layer of crushed stone screenings, which have passed a quarter or three-eighths inch mesh, with not more than 50 per cent. fine material. The entire surface is then rolled, with steam roller if possible, and if there are any black spots showing through the screenings behind the roller additional screenings should be applied, and again rolled until the black spots do not show after the rolling. After a period of from two to six weeks, depending somewhat on conditions, the loose dust and screenings which have not been bonded can be removed, leaving the surface perfectly smooth and clean. The first application of Tarvia generally makes the road dustless for about a year. Applications thereafter are necessary every two years, less and less of the preparation being used.

THE TURRET LATHE FOR CYLINDER BORING.

Several interesting features of the latest methods in use for boring cylinders for automobile engines were brought out in a chat with one of the best-known builders of boring mills, says I. B. Rich, in *The American Machinist*. Feature No. 1 was that while many boring mills were still used for this work, the tendency was to get away from them to something that would give good results and faster time. So the boring mill is to some extent giving way to the large turret for this work. The cylinders are roughed out with an ordinary boring bar having a flat cutter keyed through its center. This bar is held rigidly in the turret and supported at the outer end where possible. This rough bores in very quick time. Then the cylinders are laid aside for a day or so to allow the internal strains of the castings to relieve their pent-up emotions before being finished in the same machine. The finishing cut is taken with a two-bladed boring bar, which is adjustable for size, but in this cut the bar "floats," being connected through a flexible joint. This produces a good cylinder. It emphasizes two principles. One is the best work of this kind cannot be done at one setting, but that the iron must have time to adjust itself before the finishing cut. The other is that for the finishing cut the boring bar must not be rigid.

A STRETCH OF PICTURESQUE ROADWAY ON THE MONTGOMERY TURNPIKE AT ROSEMONT, PA., RECENTLY TREATED WITH TARVIA.

THE COST OF AUTOMOBILE RACING

OWING to the widely differing nature of the regulations governing the important European road races this year, automobile manufacturers are called upon to spend a larger amount of money on racing than before. Competitions are in a transition stage. Three years ago the 1,000 kilos weight limit was applied to the Gordon Bennett, the Ardennes race, the Brescia circuit, and the Vanderbilt contest. When the Gordon Bennett cup was sent to the museum new racing rules were spoken of, and last year the French club broke away from old conditions when it announced that its 1907 race would be held on a limited fuel allowance. Other clubs dropped their orthodoxy with the result that now not a single race in Europe is being run on the old regulation limiting weight to 1,000 kilograms. For the Grand Prix a gasoline allowance of about one gallon per ten miles is allowed; the Ardennes circuit limits the cylinder area and fixes a minimum weight; the German Emperor's cup is run under the same regulations as its Belgian companion; and for the Targa Florio there is a limited bore and stroke together with a minimum weight. The Brescia circuit, which is to be revived this year, will probably adopt the same regulation as the Ardennes and German Emperor's cup. The Vanderbilt race still remains in a doubtful state so far as governing regulations are concerned. Probably in a year or two international committees will have mutually agreed on the ideal type of rules for road races, and a car built for one race will be eligible for all other big contests throughout the world.

This year manufacturers are obliged to build three different types of racing machines to suit the different regulations. Several French firms making a point of being in every speed contest, have built one set of machines for the Grand Prix, another for the German Emperor's cup, and a third for the Targa Florio. Thus their already high racing expenditure is now trebled. It is interesting to inquire how much is spent in this fascinating but costly struggle. Paul Meyan, who has closely studied this question, gives \$102,400 as the total racing expenditure for any firm taking part in the six most important road races of the year: Targa Florio, German Emperor's cup, Grand Prix, Ardennes Circuit, Brescia Circuit and Vanderbilt cup.

There are three distinct regulations, therefore three separate types of machines must be built, nine in all. Designing may be put down at \$600; models would cost about \$1,000; for raw material, iron, steel, aluminum, etc., \$9,000 must be calculated. To turn all this raw material into finished parts expensive machine tools and skilled workmen are required, the cost of which cannot be calculated at less than \$2,000. Finally all the parts are ready and assembling begins. This would occupy about 3,000 hours' work, worth \$600 on the French scale. The three racers completely finished, they are sent on the road to undergo a 1,000 miles test, enter the factory again, are dismounted, modified, re-assembled, and finally tested. This work cannot be valued at less than \$1,800. To recapitulate, the factory expenses are:

Designing	\$ 600
Models	1,000
Castings and raw material.....	9,000
Machining	2,000
Assembling	600
Testing	1,800

First total\$15,000

As there are three different types of cars to build for 1907 this total must be tripled, giving \$45,000.

Engagement fees for the Targa Florio, German Emperor's cup, Grand Prix, Ardennes Circuit, Brescia, and Vanderbilt cup, supposing the maximum number of cars are entered for each contest, would call for an expenditure of \$9,400. Drivers, ma-

chines, attendant workmen and stores must be sent to Sicily, Germany, France, Belgium, Italy and America. These expenses cannot be calculated at less than \$3,000 per race, making \$18,000 for the six world's races. Insurance of drivers and material may be estimated at \$200 per car and per race. As there are eighteen racers the total would be \$3,600.

Nothing must be left to chance, consequently all necessary material, gasoline, oil, tires, etc., are transported to the scene of each race at a cost of \$2,400, or \$14,400 for the six races. Adding the items together, we get:

Engagement fees	\$ 9,400
Traveling expenses	18,000
Insurance	3,600
Material and stores.....	14,400

Second total\$45,400

Participation in a big race involves more or less advertising; the amount varies considerably according to the value laid upon this item by the interested parties, but \$12,000 is only a very modest estimate.

The total expenditure for the racing season thus evolves itself as follows:

1. Constructing machines.....	\$45,000
2. Racing	45,400
3. Advertising	12,000

Total\$102,400

These figures are based on the assumption that the firm will enter in all the six important races to be held in Europe and America this year. In reality only three French firms have made arrangements for such an elaborate program. There will, however, be ten firms in Europe which will incur an expenditure of sixty to seventy thousand dollars this year for racing alone. The amount is higher than it need be owing to the disagreement on racing conditions, but it is a very small amount compared with the volume of business done by the world's important factories. The leaders of the industry, in Europe at any rate, are convinced that the lessons learned in automobile construction as the result of the fierce struggle, and the advertising value of the races, are well worth the expenditure which they involve.

AERIAL TRAVEL IS ALSO COSTLY.

PARIS, April 13.—There does not appear to be much that is of great value in the huge, lightly constructed, canvas covered frames which scutter about on the Bagatelle polo ground in the early morning or as shades of evening are falling, like huge birds deprived of their natural powers of flight. There is only a light frame, generally of bamboo, with a covering of parchment, linen or thin wood, a mass of wire stays, a gas engine and a propeller. Yet this simple looking machine will have cost its ambitious owner not far short of \$4,000. The big frame cost about \$1,000 to design and construct; the propeller is worth \$160; the motor cannot be valued at less than \$1,600. Wheels, transmission gear, accessories, repairs and wages of attendants will round up the sum. Santos-Dumont is constructing his sixteenth machine and half a dozen more aeroplanists have built more than four each. An estimate of the amount spent by these leading figures in the world of flight can thus be easily arrived at.

Dirigible balloons are much more costly and quite out of the reach of the ordinary mortal. The *Patrie*, which the Lebaudy Brothers sold to the French Government, is valued at \$70,000. Two other steerable balloons of the same style have been ordered at \$52,000 each. The steerable balloon with which Walter Wellman hopes to reach the North Pole cost a paltry \$28,000.

ployed in the selections. To appear fetching in auto garb is largely a matter of millinery. Given a becoming hat and veil, a woman cannot help attracting favorable comment.

Modish women automobilists are fond of the little French hats with peaked fronts or soft brims that may be adjusted to suit the individual. Some of these have pongee or crêpe de chine curtains with long ties, while others equally as smart are held in place by big square veils arranged in any desired fashion. These veils measure two yards each way and are found in a large range of attractive combinations. A stunning veil of this type is deep cream color with cardinal polka dots and two-inch border. Another in white decorated with empire green is shown among the stylish effects. A five-yard-long veil has a white silk mesh center with brown chiffon ends; the white part is intended to cover the face and the ends arranged over the hat and hair ending in a big bow at the throat.

THERE'S no diminution in the cry for smart clothes for use in automobiling. With enthusiasm affecting a growing army of autoists, makers of apparel have accomplished some wonderful achievements in the way of appropriate and fashionable toggery. There was a time, and not so very long ago, that automobile clothes were considered a luxury, but now all this is changed, and as stunning an outfit as one might wish can be owned at small cost. For example, a fashionably cut coat of imported worsted, rendered rainproof by a chemical process, is now being sold for \$20 instead of \$33, as was the case two years ago. Makers of automobile clothes have succeeded in providing more desirable garments than ever before for the discriminating feminine automobilist, and with models fashioned from the latest ideas of the best European designers to aid them, American dealers

are enabled to offer equally as smart fashions as one sees on the Continent and at wonderfully attractive prices. The accompanying illustrations will give an idea of what the best toggery shops are selling. When touring for long or short distances one is obliged to consider the question largely from the standpoint of comfort, but when driving through the park there is no possible excuse for one to appear dowdy. There are so many fascinating coats and hats that nearly every type can be suitably fitted if only a little discrimination be em-

ployed in the selections. To appear fetching in auto garb is largely a matter of millinery. Given a becoming hat and veil, a woman cannot help attracting favorable comment. Modish women automobilists are fond of the little French hats with peaked fronts or soft brims that may be adjusted to suit the individual. Some of these have pongee or crêpe de chine curtains with long ties, while others equally as smart are held in place by big square veils arranged in any desired fashion. These veils measure two yards each way and are found in a large range of attractive combinations. A stunning veil of this type is deep cream color with cardinal polka dots and two-inch border. Another in white decorated with empire green is shown among the stylish effects. A five-yard-long veil has a white silk mesh center with brown chiffon ends; the white part is intended to cover the face and the ends arranged over the hat and hair ending in a big bow at the throat.

A charming example of how to make a picture of oneself in an automobile was exhibited by a well-known society matron a few days ago when she motored into town for a glimpse at the new spring bonnets. She wore a Scandinavian leather costume in that lovely new shade of red called dahlia; it is that soft, pinkish red obtained by uniting crimson and cerise. The skirt was made with a fitted yoke that ended below the hips in rather small scallops. The lower part was cut with many gores that flared considerably from the yoke to the hem. A trig little Norfolk jacket trimmed with stitched straps and further ornamented with flat gilt buttons reached the lower edge of the skirt yoke. A stunning hat with stitched suède brim and shirred silk crown was decorated with two long wings that inclined backwards. The effect produced was one of rare taste and discernment in costume design. A cream

WHITE MOHAIR, LEATHER TRIMMED.

colored crêpe de chine veil with tucked ends protected the face and crossed at the back, where they were tied in a fetching bow that floated in the breezes a distance of a foot or more. White cham- ois gauntlets added the desired chic to the outfit. For general hard use there is nothing like a motor coat of some serviceable cloth made with ample fullness and easy of access. Leather trims a number of the smart- est models when it is applied in the form of strappings or merely as collar and cuffs. An attractive loose coat of rainproofed cloth in gray, with

THE GIBSON COAT IN LEATHER.

SILK RUBBER RAIN COAT.

Courtesy of Auto Supply Company.

light blue cross bars is trimmed with rain-spot proofed velvet. The yoke is distinctly new and practical, being fastened, as it is, on the shoulder instead of the front, where the wind has full play. The shape of this new yoke-cape, as it is best described, is particularly becoming and offers just enough of a dressy touch to make the coat suitable for all-round wear. Fancy metal buttons decorate the cape and close

worn by automobilists. An elegant silk coat in golden brown seen this week was loose fitting at back and front and had big fluted revers that fell back, revealing a sumptuous waistcoat of lemon colored leather fastened with gold buttons. The sleeves were big and long and were completed with satin wind-cuffs concealed inside the lower edges. Pongee in natural and all fashionable shades is shown extensively in the realm of smart materials for semi-dressy clothes. There is hardly anything that quite comes up to the dustproof qualities of pongee and in the best imported stock a frock or coat will look well an entire season. When the automobile spin is to end at a fashionable restaurant or theater the pongee costume with top coat to match is smart. Some of the imported pongee motor dresses are charming enough for street wear, many of them being designed by the world's best dressmakers and displaying endless amounts of exquisite hand work.

Going back to the waistcoat question, there are some elegant ones in leather, made both with and without sleeves. The double-breasted style is generally preferred and the fondness that some women have for costly buttons falls short of downright extravagance. Sometimes the waistcoat buttons will be studded with jewels to match the color of the leather; then again they will be gold filigree or etching. Antique silver buttons with big square buckles in corresponding design are shown among the recent importations, and if the craze continues we soon shall see automobile jewelry in general use.

Apropos of motor accessories, certain clever milliners are providing skillfully shaped hats, with adjustable brims, that can be turned over the back of the head, completely covering the hair. The illustration represents one of the smartest of this class in Copenhagen blue straw, trimmed with a band of velvet and two rosettes. This quaint little model may be worn in half a dozen different ways and each one equally becoming. Sensible little caps of tweed or pongee, with visors fore and aft and flaps which may be worn over the ears or fast-

A COMFORTABLE TOURING COAT.

Courtesy Scandinavian Fur & Leather Co.

the fronts with a long tab. A full crown cap, with deep visor made of the same cloth, accompanies this very desirable garment and gives a very fetching effect to the whole gown as an ensemble.

Quite out of the ordinary but very elegant is a long semi-fitted coat of white mohair, trimmed with bands of black patent leather. A helmet with full plaited crown and cunning little mushroom brim is simply finished with a band of patent leather. The style is particularly well adapted for any style veil or hood and while one might imagine from the description that the shape would be trying, on the contrary it is generally becoming. Another fascinating coat for rain, wind or dust is of rubberized plaid silk in the loveliest of rich colorings. The pointed yoke is finished with pipings and the full sweep of the garment gives it a wonderfully attractive style all its own. Big puffed sleeves, finished with close cuffs, are cut in such a way that they slip over almost any style dress sleeve without disarranging its folds. A pretty little head-covering for rainy weather is in the shape of an evening hood, made to fit snugly and finished with a curtain to shed the water. The peaked top gives just enough of the picturesque to make the style attractive.

One of the newest and most dressy costumes is in elephant gray leather, trimmed with touches of crimson leather. The model is one of the smartest shown this season and is made in the Gibson style, with broad shoulder effect, full bishop sleeves and fitted body held taut by a narrow belt which joins the skirt to the waist. A knee depth circular flounce completes the lower part of the garment. Three exquisite buttons in gun metal filigree over red enamel decorate the front, that closes a trifle to one side. With this stylish costume is shown an odd little flat hat having its oblong brim stitched to give it desired firmness; the quartered crown combines both gray and red leather. Several different effects can be obtained by slight turns and twists of the brim, which makes the model one of the most desirable brought out this season.

In fashionable quarters one sees a host of beautiful empire coats

ened up on the cap, are popular for long runs in the country. Sometimes the goggles will be inserted in the front visor, in which instance the visor is adjustable and can be turned up like the ear flaps. A practical gauntlet has slats in the cuff that preserve its shape and render it possible to fold in extremely small package. These in dogskin are among the novelties lately unboxed by one of the well-known dealers.

In and About the Crescent City

By Felix J. Koch

PURE COUNTRY MILK.

HE was from the North, obviously; had had his auto shipped to the Crescent City, where it would be transferred for the trains going West.

The time hung idle in New Orleans, just a sort of holiday, between trains. Why not put it to advantage? So he resolved to hunt out queer corners of the Crescent City en automobile.

Whither and whence! He would let fancy dictate. A "Coliseum" car came along and he followed behind. It was Springy, and warm, here, this April day, but folk were wearing overcoats, and he, from the North, wondered why. He could see an old darkey "mammy" leading "massa's" children to church, and it recalled the South he had read of. He noticed the absence of barber-poles; that, down here, instead, shops had the entire front painted in red and white stripes.

He circled about the Lee Monument, toward the pretty places with their balconies out over the walk, to pillars along the curb, and it recalled the Norman cities he had autoed to. One old place had a wistaria growing over its several porticos. He stopped to maneuver past some boys playing ball here in the street, turning down a square of massive palms to a boulevard, that captivated him fairly. In the center of the street was the asphalt walk. Then a strip of lawn with the shade trees. After this, on either side the car tracks, and then the street itself, with the walks overhung with trees, now bearing their wealth of new spring leaves. There were men everywhere, working on these streets, and this despite the Sabbath. Many of the shops, too, were open, and the bootblacks were very busy. By and by he skirted a park, rather pretty, though but a square in width, and given over almost wholly to China trees—umbrella-shape ever and always. Children were skating here on the walks, as they did in his home city.

Some of the Odd Characteristics of New Orleans.

Then he came to the "Coliseum"—a music hall he took it to be, but just the sort of old three-story Southern place he had wanted to "bag" with his kodak. Other, even prettier places, with fluted pillars to their porticos were here, and there were tennis courts in the gardens. He carried a note book, as all careful autoists should. He recorded the number of winter cars that went by, though this was to him warm spring weather. He recorded the signs everywhere about town, warning strange girls to beware of strangers, or against entering positions whereof they do not know the mistress, and it reminded him of San Francisco. Fig trees, such as he had seen in Paris gardens, were in the yards here, and their quaint Frenchy trellises, with iron spears, it seemed, set against iron uprights. Set among these fine old places was Tulane College, with its ancient piles rising amid the trees. Roofs of the houses were built projecting out against the sun everywhere in this section. Little lads with kites played on the way or in the "neutral ground," as the lawn in the street center was called.

Here and there he noticed queer pedestrians: Men with odd wicker bread baskets on their backs, such as he'd seen in Bulgaria. Again he stopped for a snapshot of the stock-brick Southern University, an old three-story edifice, with its center-front indented behind four pillars and its campus starred with trees.

A typical Southern home, such as he'd imagined Sinclair's of "Uncle Tom's Cabin" to be, was here—this and a great asylum, and then the car barns. He felt he'd about reached the outskirts by this time, though there were more gardens with the folks sitting out in them, so he turned and looked for guides.

Following the car line didn't seem such a bad plan after all. Another car, marked "Henry Clay Avenue," came along, and in pursuit of it he went. Aside, however, from an occasional old negro, a quaint typical Southern type, and the "ads" of a certain "Aunt Hannah's Death Drops," and a queer southern church completely covered with ivy, except at its long, plain windows, this "up-town" section did not afford him much. In fact, small places, with awnings along the street, seemed to comprise most of the way.

By and by he was back at his caravansary. The sun, however, shone so bright it seemed no day for indoors in hotels. And what was more, he would test the cafés of New Orleans. He followed the crowds toward Fairbacher's, one of the old-timers, beyond all advertisement. There he partook of calf's-head *a la Creole*, cooked with mangoes and okra and tomatoes. Then chicken livers and beer. He noted the restaurant and its compactness. Down one side a brass rail extended, and beyond this there was a marble lunch counter, with shelves of white marble behind it, and on the top of this the pies. Mirrors with the prices painted here and there on their faces and tapestries representing varied viands completed the picture, save for the little white-clothed tables, seating four apiece, at 'tother side the rail. The food was excellent and well served.

How the City Looked in the Afternoon.

After the meal he stopped a moment, as he paid at the door, to watch perhaps fifty of the city street cleaning carts, in line, going out for the day's work. Seated on each was a negro, wearing a bright red shirt for uniform and marking the procession from afar.

Again he took the car for guide, this time toward "Bayou St. John." It led him through the negro section, a section much like that of a Turkish town, even to the dumping of slops out in the street, and made him wonder that yellow fever was not more prevalent than it is. Women, carrying their babies here, had a great veil tied from their arms, across the child to the mother's shoulder, so as almost completely to inclose the infant.

Then he came out at the bayou with its skiffs and other boats. Incidentally, he could do some sightseeing. But a few blocks away was the famous City Park track, where the races were then on. It was a good place to "rest" the auto, and, for a time, he nosed about. Took snapshots of Lady Katherine, a descendant of Roselyn III, the famous two-year-old of the Colonel, and Sweet Sunshine and other steeds. Then, of the racing men scattered promiscuously about, among the fifty cent and dollar seats everywhere.

The center of the park was one great lawn, about which a white-painted fence stretched, and then, encircling this, a broad gravelly track. This in its turn was encircled on one side by the long, one-story horse sheds, such as he had seen at the home city, and among which a man was just then peddling bananas. Over on the other side the large two-story stable of Colonel Nemo, famous as a turfman, arose, these and those of another race man, built in the southern style. There was the large, modern grandstand, and before this, at the track, the starter's cupola. Opposite this, the signboard with the time of the different horses coming in, the clock and the bell. In distance, he could see the mile-posts marking out the course.

Somchow or other, however, city autoing was paling by this time. He turned cityward with just a trifle of a surfeit. Going out he had passed a theater, where the poorer class seemed to go. It might give him a peep at New Orleans's underworld, so

he left the auto in garage. As it proved, the theater was the Lyric and the play nothing worse than "David Copperfield."

Here was still time for a parting glance at New Orleans. From the St. Charles he sent his *chauffeur* down to the train with the valises, and then betook himself to the stores for souvenirs of his stay. Little bales of cotton, with darkeys bearing rice strands atop, were the most typical things he could find.

Again the call of the French restaurants lured him. He stepped into one, where the orchestra was playing the "Blue Danube," and following this up, then, with "Give My Regards to Broadway."

It was supper time in New Orleans, and he was curious to see what they ate. Six fried oysters, of which the people are inordinately fond, buying at thirty cents the half-dozen, chicken salad, beer and a charlotte russe seemed a favorite combination. He admired the young women with their sleeves cut at the elbow; he admired the gallant young men. By and by the clock showed him that it was time he were stirring. The auto by this time would be aboard the car.

Wearily he retreated to the hotel for his parcels, and the great postal album he would carry. Then, equally weary and somewhat stiff, he loitered down to the train.

The berth in the sleeper looked decidedly good.

GERMAN NOTES.

BERLIN, April 9.—Entries will soon close for the Herkomer, and they promise to outstrip all expectations. Great preparations are being made everywhere to make this third contest a record one, but till now it has not been possible to go entirely over the course owing to the snow in the mountains. The Dresden - Chemnitz - Zwickau route, originally the bugbear of the committee owing to its water-cuts, is now in very good order.

A company has been formed at Munich to open up a line of motor coaches in the neighborhood of the Bavarian capital, penetrating for the present as far as Kochel in the Bavarian Alps, with further extensions later on. Four different tours have been fixed for the present, and the fares are moderate.

TULANE UNIVERSITY, NEW ORLEANS.

OLD FRENCH QUARTER OF THE CRESCENT CITY.

OUT THE BOULEVARD TO THE CITY CEMETERY.

A TYPICAL SOUTHERN HOMESTEAD.

NEWS IN NEW ORLEANS.

NEW ORLEANS, April 20.—Owing to the fact that the roads in and about New Orleans are not in a condition suitable for automobiles, time and endurance races in this section are not common. The only road leading out of New Orleans is one that follows the course of the river for some distance. In good weather the cars can run at full speed safely, but after a series of rains, passage over them is very difficult. It is believed, however, that there is an old military road

leading out from Covington, La., to Memphis, Tenn., which, if it is true, will afford the autoists a new field for their operations. Palmer Abbott has recently ordered a large shipment of cars to New Orleans, one of which will be shipped to Covington, as there is no direct road between there and New Orleans. He will then go to Covington to investigate the road for himself. If it is found desirable it is thought that several races will be arranged for in the near future, as there are a large number of enthusiasts in the city who long for excitement beyond the asphalt.

The Louisiana Automobile Association has not been doing much of late, and interest in that particular direction seems to have somewhat dissipated itself, despite the fact that the sale of cars in this city continues to be rather large.

The only tour of any particular note which has taken place lately occurred about a month ago, when Earl Knobloch made the trip from New Orleans to Thibodaux and back, a distance of 250 miles, in fourteen hours. Mr. Knobloch says that that is about record time for the trip, and shows an average

of about 18 miles per hour. He made the trip in a 1907 Oldsmobile, leaving New Orleans Friday at midnight, and arrived at Thibodaux, having passed through Donaldsonville early Saturday morning, and having made only one stop, for his breakfast. At 2 P. M. the party started home, arriving here at 9.30 Saturday night. The tool kit was not touched throughout the trip. The roads on this particular trip were good, which cannot always be said of them, though of late years they have been improved.

SPRINGTIME'S ADVANCE STIRS CLUBS TO ACTION

Canada Has an Active Club at Winnipeg.

WINNIPEG, CAN., April 22.—The annual meeting of the Winnipeg Automobile Club took place April 17, when the following officers were elected: Patron, Sir Daniel McMillan, Lieut. Governor of Manitoba; honorary president, J. C. G. Armytage; president, Judge Phippen; first vice-president, R. M. MacLeod; second vice-president, T. M. Belcher; secretary-treasurer, W. C. Power. Forty-seven new members were elected, bringing the total membership of the club to over 100, and a further election of some thirty members will be balloted for at a special meeting to be held at an early date.

It was decided to promote a reliability contest extending over a period of not less than three days, the choosing of the routes to be left to the touring and racing committee for selection. The entries will be divided into two classes, the first for touring cars and the second for runabouts. Handsome trophies will be provided for competition.

A special legislative committee was also appointed to watch the interests of automobilists in regard to any measures that the authorities may bring forward for the control of automobiles in Manitoba, and a special member's card will be provided, signed by the president and the chief of police in order that the members can be saved the necessity of proceeding to the police station under arrest in case of trouble, the card being accepted as a guarantee for appearance when summoned to attend.

The retiring secretary, A. Emmett, who has held the position for the last three years, was presented with a purse in recognition of his services to the club.

The good roads movement organized last year is receiving the support of every user of a vehicle of any description, and great efforts are being made to boost the movement to a successful issue. Government support is being sought for road improvements and a special grant will be asked for at the next session of the provincial legislature.

Motorcycling at Harvard is Popular.

CAMBRIDGE, MASS., April 22.—Motorcycling is having quite a boom at Harvard University. The motorcycle club organized there two years ago has taken a new lease of life, and will begin work in earnest this spring. The club was founded in 1905 by L. E. French, H. G. Hawes and W. M. Davis 2d., and held a successful hill climb that year on Commonwealth avenue, Brighton. The attempt at organization proved rather premature, however, and only recently has much interest been aroused. Now there are about twenty machines in use in the university, and it is believed that the owners of all of these will join.

The club has made arrangements with the Harvard Automobile Company for the storage and care of members' machines at reduced rates in the new garage on Quincy square. Weekly runs will also be held as soon as the roads are in suitable condition, and another hill climb is in prospect. Nothing definite has been decided about this, but the date will probably be April 30.

Sons of Eli Form the Yale Automobile Club.

NEW HAVEN, CONN., April 22.—A meeting of all the men in college interested in forming the Yale Automobile Club was held last evening at the University Club in this city. After a general discussion as to organization, the following officers were elected: President, George H. Townsend, '08; secretary, W. Morden, '08; treasurer, E. H. Butler, '07. A committee of four was appointed by the president to arrange a series of meets and hill-climbing contests. Thirty members have already shown their intention of joining the club.

Washington Club Objects to Young Drivers.

WASHINGTON, D. C., April 22.—The Automobile Club of Washington is favoring the adoption of a proposed amendment to the automobile regulations prohibiting the operation of automobiles by all persons below the age of eighteen years. Such a regulation has been drawn by the corporation counsel and it will probably be put into effect within the next thirty days. The proposed regulation was framed at the suggestion of the District Attorney, who stated that the grand jury now sitting had called his attention to the number of accidents resulting from the operation of automobiles by boys.

It will be remembered that the automobile board of the District of Columbia has frequently recommended the adoption of the 18-year age limit, on the ground that persons under that age are physically unable to operate automobiles. As far back as 1903 the matter was referred to the then corporation counsel, who stated that while it was within the power of the District commissioners to promulgate such a regulation, he did not deem it expedient to adopt an iron-clad rule, as to refuse to permit everyone under 18 years of age to operate a car would manifestly prevent the use of automobiles by persons who are fully as competent as persons much older.

On the other hand, Secretary Woodward, of the automobile board, does not believe that any distinction should be made. He states that in his opinion not one boy in a hundred is competent to handle a car at a time when a cool head is required, no matter how skillful a driver he may be.

Yorkians of Pennsylvania Re-elect Officers.

YORK, PA., April 22.—A pleasure run was arranged and officers for the ensuing year elected at the annual meeting of the York County Automobile Association. The pleasure run will be from this city to Hanover and return, Sunday, May 5. The local autoists were extended the invitation through Thomas J. O'Neill, the second vice-president of the association, who resides in Hanover.

All of the association's officers were re-elected as follows: President, Dr. J. F. Klinedinst; first vice-president, Clarence A. Geesey; second vice-president, T. J. O'Neill, of Hanover; treasurer, Gordon Nes; secretary, Stuart B. Lafean. During the meeting the coming endurance run of the Harrisburg Automobile Club was referred to, and it is the general opinion here that many Yorkers will contest for the cups. The first night's stop in the endurance run will be made in this city.

President Duttenhofer Re-elected by Cincinnatians.

CINCINNATI, April 22.—At the annual meeting of the Automobile Club of Cincinnati, the following board of governors and executive officers were elected for the ensuing year: President, Val Duttenhofer; first vice-president, Dr. A. B. Hyl; second vice-president, F. N. Temple; secretary, Dr. L. S. Colter; treasurer, C. Gordon Neff; consulting engineer, E. J. Carpenter; governors, the above and Dr. McKim Cooke, Gustav W. Drach, Dr. C. L. Bonifield, W. B. Gotherman, Harry L. Mauss.

The annual report of the secretary showed a membership of about 200. It was voted to appropriate \$1,000 to be expended by the committee on guide posts in the erection of sign boards at the intersection of all the prominent roads in Hamilton county, and the estimate calls for 150 of these useful indicators. The club also passed a resolution containing a number of suggestions to be forwarded to the local chief of police defining the position of the club on local conditions pertaining to automobiling, the chief of which are as follows: A firm stand against fast driving and exceeding the speed limit, particularly in the city;

advocating that the police arrest drivers with old or no tags, and smart drivers who put their tags on front of cars, instead of rear, as prescribed by the law; to discountenance the use of siren horns for city driving; to discountenance the payment of fines of chauffeurs by owners of cars when owner is not in car; to furnish members with maps of the local roads, and asking members to make reports on special roads.

Controls Selected for the New Jersey Endurance Run.

NEWARK, N. J., April 22.—The special committee of the New Jersey Automobile and Motor Club, headed by Louis T. Wiss, has made a tour over the route selected for the three-day endurance contest scheduled for May 30-June 1, and definitely named the controls which will be utilized during the run. On the first day's run the checking points will be Morristown and German Valley, stop being made at Washington for luncheon. There will be but one control in the afternoon, Somerville being designated as the place, the finishing point for the first day being at Newark. Starting from Newark on the morning of the second day, the contestants will run free to New Brunswick, where the first control will be situated. After New Brunswick will come Trenton and Mt. Holly, where the tourists will stop for luncheon. White Horse Tavern, Egg Harbor City and Atlantic City will be the checking points for the afternoon.

It is not yet entirely certain where the noon control for the last day will be placed, although Freehold is favored by the committee if accommodations can be obtained. Stations previous to Freehold will be Tuckerton and Toms River.

Minneapolis Elect Asa Paine Their President.

MINNEAPOLIS, MINN., April 22.—At the annual meeting of the Minneapolis Automobile Club, Asa Paine, formerly the club's vice-president, and president of the Florida East Coast Automobile Association, was unanimously elected to the presidency. The other officers elected are: First vice-president, Horace Lowry; second vice-president, Benjamin F. Nelson; secretary, R. J. Smith; treasurer, J. H. Riheldaffer.

Retiring President Joyce, in a short speech, congratulated the club on its growth and prosperity. He pointed out that within a year the membership of the club has been increased by 227 members, making a total of 500.

The report of the treasurer showed that the finances of the club are in sound condition and that the clubrooms have been a source of profit rather than of expense. Following the discussion of this subject the club turned to the interesting topic of good roads, and might be talking about them yet had not the call to back rooms, where a buffet lunch was ready, interrupted. The members resisted just long enough to authorize the appointment of a committee of five to confer with Mayor J. C. Haynes relative to the enforcement of the ordinance against throwing bottles, glass and rubbish into the streets.

CLUB DOINGS IN GENERAL.

Brooklyn, N. Y.—The Runs and Tours Committee of the Long Island Automobile Club, following the custom of previous years, has chosen the first Saturday in May for its annual spring run. The club's May run has always brought out a representative number of cars, and this is expected to surpass all others.

Philadelphia.—The elegantly appointed quarters of the Ladies' Quaker City Motor Club in the Hotel Majestic were opened on Monday night, the April meeting being held there. Early in May a "housewarming" will be held, on which occasion the male friends of the members will be invited.

Montclair, N. J.—It is expected the first meeting of the Montclair Automobile and Driving Club will be held next week. The plans of the organizers are to have the first meeting take place at the new Hotel Montclair, which is expected to open on May 1. Over 125 autoists are expected to join.

THE AUTOMOBILE CALENDAR. AMERICAN.

Shows and Meetings.

- May 28-31.....—Indianapolis, Ind., Annual Meeting American Society of Mechanical Engineers.
Oct. 31-Nov. 7...—New York City, Madison Square Garden, Eighth Annual Automobile Show, Association of Licensed Automobile Manufacturers.
Nov. 30-Dec. 7...—Chicago, Coliseum and First Regt. Armory, Eighth Annual National Automobile Show, National Association of Automobile Manufacturers.

Races, Hill-Climbs, etc.

- May 6-7.....—Harrisburg, Pa., Two-day Endurance Run, Motor Club of Harrisburg.
May 30.....—Philadelphia, Hill Climb, Monk's Hill, Quaker City Motor Club.
May 30.....—Chicago, Memorial Day Race Meet of the Chicago Motor Club.
May 30.....—Bridgeport, Conn., Hill Climb, Bridgeport Automobile Club.
May 30-June 1...—Newark, N. J., Three-day Endurance Run of the New Jersey Automobile and Motor Club.
June 12.....—National Orphans' Day, instituted by the American Automobile Association.
June 20.....—Albany, N. Y., Annual Tour of the Albany Automobile Club, Route, via New York and Asbury Park, to Atlantic City.
July 10.....—Cleveland, O., Start of Fourth Annual Tour of the American Automobile Association, for the Glidden Trophy. Finishes in New York City on or about July 23.
Oct. 19.....—St. Louis, Mo., International Aerial Race of the Gordon Bennett Prize. Aero Club of America.

FOREIGN.

Shows.

- May 4-15.....—Madrid, Spain, Automobile Exhibition, Palace of Fine Arts, Royal Automobile Club of Madrid.
May 15-26.....—Zurich, Third Annual Swiss Automobile Show.
June 25-30.....—St. Petersburg, Russia, Automobile Show.
Nov. 12-Dec. 1...—Paris, Exposition Decennale de l'Automobile, Grand Palais, Esplanade des Invalides, Automobile Club of France.

Races, Hill-Climbs, etc.

- April 28.....—Chateau Thierry Hill Climb.
May 4-14.....—Spring Wheel Competition, A. C. of France.
May 15-31.....—Belgium, Industrial Vehicle Trials, Automobile Club du Nord.
May 18-21.....—Milan, Italy, Touring Club Trials.
May 22-25.....—Irish Automobile Club Reliability Trials.
May 24-27.....—Voiturette Contest, Automobile Club of Austria.
May 28.....—Isle of Man, Tourist Trophy Race, Automobile Club of Great Britain and Ireland.
May 30.....—Isle of Man, Heavy Touring Car Race, Automobile Club of Great Britain and Ireland.
June 3-12.....—Paris, Electric Vehicle Competition, Automobile Club of France.
June 3-12.....—Herkomer Cup, Automobile Club of Bavaria.
June 14.....—German Emperor's Cup, Taunus Circuit, Imperial Automobile Club.
June 20-22.....—American Gold Cup, Start from New York of European Tour for American Cars, Georges Dupuy, secretary, 1402 Broadway, New York City.
June 14-29.....—Scottish Reliability Trial, Scottish Automobile Club.
July 2.....—Grand Prix, Automobile Club of France.
July 14, 1908....—Paris to London, Aerial Race.
July 15-18.....—Ostend Week, Record Trials, Automobile Club of Belgium.
July 21.....—Ardennes Circuit (Belgium).
July 31.....—Lledekerke Cup for Touring Cars, Ardennes Circuit, Belgium.
July 31-Aug. 8...—Belgium Regularity Contest for Touring Cars, A. C. of Belgium.
August 1-7.....—Criterium of France, 1,750 Miles Touring Competition and 250-mile Race for the Press Cup, A. C. of France.
August 11-29....—France, Coupe de Auvergne.
Sept. 1.....—Italy, Brescia Circuit, Florio Cup, A. C. of Italy.

SIX CARS READY FOR PEKIN-PARIS.

PARIS, April 15.—Pekin-Paris on auto is now a certainty. The Chinese Minister of Foreign Affairs at Paris, having communicated the fact that the contest is authorized by his government, June 10 has been fixed as the date of departure from the Far East. Certain starters are Fiat, Itala, De Dion Bouton with two cars, Contal with a tri-car, and Spiker a 40-horsepower Dutch machine. An illustration is given herewith of the Contal tri-car to be driven by Pons, fully equipped for its long trans-Siberian journey. The power plant is of the standard type, but the machine has been specially equipped and fitted to carry the spare parts and special tools which may be needed for a journey over a country which has never known other modes of locomotion than the camel caravan. Pons is shown crossing an imaginary ditch by means of the portable bridge which he carries with him on metal brackets at each side of the car. He has a complete camping outfit, for frequently the automobilists will have to pitch their tent in the open air, far from dwellings, spare tires, and extra provision for gasoline. The Spyker has an open touring car body, the entire tonneau of which is fitted up with spare parts, jacks, tools, camping outfit and the thousand and one necessaries for such an adventuresome trip. The whole is

EN AUTO TO THE FINAL RESTING PLACE.

Automobile electric hearses have been introduced in Berlin by the company which first placed the taximeter cab in service in that city.

Small bars of lead are very useful in adjusting the finer parts of a machine. The bars can be readily held on the strap, or key, or bolt head, and a straight and effective blow can be struck by the ordinary hand hammer. In any event, the copper hammer, so-called, should be abolished or reformed altogether. The element of durability is its worst feature. It hardens as it grows older. Its blows mar the finest features. Like the leprosy or the smallpox, its victims are known at a glance.

FRENCH TRI-CAR EQUIPPED FOR PARIS-PEKIN RUN.

covered over with a tarpaulin mounted on a light frame. Pons, the Contal driver, left Paris this week by road for Marseilles, where he will embark on the Oceanien for the East. Cormier, the De Dion conductor, left here a week ago by train for Pekin to make arrangements for establishing gasoline and tire stations on the route. His machine will leave from Marseilles together with that of Pons. Although the German consul at Shanghai states that the majority of automobiles in that city are of American and British manufacture, these two nations are not represented in the tour.

ABUSE WITH THE HARD "SOFT" HAMMER.

Thirty or forty years ago there were hammers made of babbitt that were really soft and left no mark. Now they are made of scrap copper or dross of bronze or other indescribable compounds, says the *Mechanical World*. Knuckles and corrugations gather on their wrinkled faces, and their impressions can be seen and felt all around the twentieth century locomotives. The mechanic who has ever finished a strap knows that there is a silken softness about a finely finished strap or other highly polished unhardened metal. He begins operations with a block of wood. The soft hammer breaks the wooden block into a thousand pieces, and there is no time to keep up the supply of timber, so in the general hurry and confusion incident to getting the engine out the alleged soft hammer begins to get its work in. Hammers of lead or babbitt are comparatively harmless, and easily made.

SOME JOYS OF CAMPING A LA AUTOMOBILE.

As a means of recreation during the dog days of summer, it must be admitted that there are few things to equal camping, but when, to add to its pleasures and rob it of some of its inconveniences, the automobile is thrown in, it is indeed a pastime for kings. Not a few venturesome autoists in appreciation of this have fitted their cars up in various ways, some of them with most wondrously contrived kits, others utilizing the car both as a conveyance and as a sleeping room. The accompanying photograph pictures somewhat of a variation on any of the foregoing, for it may well be termed a typical automobile camp, in that a canvas garage has been provided for the car, in addition to the "grub" and sleeping tents.

The car is a Thomas Flyer and is the property of Hon. S. R. Dresser, Bradford, Pa., who is an advocate of the open-air life. For the ingenious method shown of sheltering the car against the weather while in camp, his chauffeur, F. C. Rupp, is responsible, and it is one that may be followed to advantage.

Tire Limitations Be- Nothing has better demonstrated
coming; Better Recognized—the force of the saying that the
 more a man knows about a thing the less disposed to complain
 he becomes, than the past year or two of tire history. True,
 there are still those who damn the pneumatic tire unceasingly
 and try something else, only to come back to it in the end; they
 are the ones who have yet to learn. Once they have matriculated
 and joined the ranks of the seasoned autoists, they no longer
 waste time in vilifying pneumatic tires in general and the one
 brand of their personal experience in particular—simply because
 they know. No one is in a better position to realize that, despite
 all its shortcomings, there is nothing to replace the pneumatic
 tire than the autoist who has been induced to join in the hunt for
 this will o' the wisp by unfortunate early experiences. The
 majority learn without going through the mill of substitutes.

The autoist who knows realizes that there are worse things
 than punctures, and does not sacrifice his all to gain this one end.
 There can be no gainsaying the fact that tire maintenance is still
 the most substantial item in keeping a car, but experience has
 shown that, with other forms, speed and comfort are sacrificed
 to a very questionable gain in outlay; it would perhaps be truer
 to add that the expense has not been decreased materially—
 simply transferred to another account. Commendable efforts are
 being made to discover a working substitute for the pneumatic
 tire, and the number of devices already brought forth is legion.
 Many are ingenious, others promise well, but none is quite the
 equal of the rubber-confined compressed-air cushion. Like gold,
 rubber comes high, and near-rubber in a tire is just about as
 valuable as near-gold in jewelry; there are numerous things

which have many of its attributes, but they all lack the one most
 important—they are not rubber. Experience has shown that,
 given the proper sizes to begin with, a little care and reasonable
 use means value received from the pneumatic tire in every
 instance, and this is what the average autoist has come to realize.

Consideration for Other Users of the Highway

"To sum up the whole situation, the motorist on the road can ill afford, for the sake of the sport, to make a single bad friend by any act of omission or commission," says Charles J. Swain, president of the Quaker City Motor Club, in the course of an article entitled "Courtesy on the Highway." Unfortunately, there are far too many autoists who consider the vastly greater power and speed at their command than is granted to other users of the highway to control, as sufficient license in itself for ignoring any rights those others may possess. The autoist who is also a horseman, and who has occasion to use the country roads himself when drawn by the faithful Dobbin, is in a position to realize the helplessness of the man behind the horse, as well as the feeling of impotent rage which sweeps over him when he sees his rights thus deliberately trampled upon. To be commanded peremptorily to clear the road by a car yet half a mile away, with its long-drawn wail, is certainly bad enough.

But it does not compare for an instant with the wholly inconsiderate habit the same type of user has of rushing around corners on narrow country roads without giving a thought of what may lay beyond. Mr. Swain remarks, in the course of the article referred to: "I would lay special stress upon consideration for the farmer. The harboring in his mind of an injury, real or fancied, cannot but incur his enmity." Surely this habit of attempting to usurp the entire highway, both on straight stretches and turns, is not a fancied wrong; it is the prolific cause of accident and always of hard feeling. Only through consideration for other users of the road, which is regrettably absent in the actions of a number of autoists, can the advocate of the power vehicle, who uses the road for his pleasure, and the country resident, to whom it is an absolute necessity, meet on a common ground.

Increasing Use of Anti-Friction Bearings.

In few essentials of the car is the general trend toward improvement more noticeable than in the constantly increasing use of anti-friction bearings of different types. As it first came forth, particularly in this country, the automobile was a piece of mechanism that depended upon the regulation type of plain bearings for practically all of its moving parts. The lessons taught by the bicycle were shortly taken advantage of, so that almost from the beginning at least the road wheels have run on an anti-friction bearing, patterned at first after bicycle practice. It required an equally short time to demonstrate that both the plain bearing and the old ball bearing were unsuited to the new duties.

Next to the wheels, the part of the car that showed itself to be most in need of an improved type of bearing was the change-speed gear box, and there is little doubt that experience in the use of ball bearings on this essential has done much to further their adoption on other parts of the car. The same is true of the roller bearing, of which two or three types are in current use both on wheels and in change-speed gear boxes as well as for bevel-gear drives and rear axles. In short, the car that does not employ some sort of anti-friction bearing, at least for the sliding gear set, is an exception that would be difficult to locate. From this it has been but a step to the introduction of such bearings in the motor itself, and though the number thus equipped is still considerably in the minority, the fact that their use for that purpose is on the increase is evident. It is scarcely necessary to enumerate their advantages over the plain type in any capacity on the car; the chief drawback would appear to be that of initial cost, but the greater durability and freedom from trouble accompanying their use are rapidly overcoming that objection.

MICHIGAN'S A. A. A. STATE ASSOCIATION.

DETROIT, MICH., April 22.—As expected, there was little difficulty in forming the Michigan Automobile Association of the A. A. A. Representatives of the Grand Rapids, Saginaw, and Detroit clubs met in Detroit last week and perfected an organization in a few hours. These officers were chosen: President, Edwin S. George, Detroit; vice-president, Dexter M. Ferry, Detroit; secretary, Dr. D. Emmett Welsh, Grand Rapids, and treasurer, J. R. Jackson, Grand Rapids. Paul H. Deming, a member of the national touring board and of the Detroit Automobile Club, was named as a director.

The Detroit, Grand Rapids and Saginaw clubs are the charter members of the new organization, but assurances have been received from Kalamazoo, Muskegon, Battle Creek, and Jackson that automobilists in those cities are taking steps to organize clubs which will join the State body.

D. M. Ferry, Jr., was made chairman of the State legislative committee and J. R. Jackson, of the membership committee.

The forming of the association will mean considerable to automobilists of the State. It will insure for one thing that there will be annual runs between Grand Rapids and Detroit. Grand Rapids will offer prizes at this end of the line for the Detroit enthusiasts to compete for, and the Detroit club will offer prizes for local autoists to contest for. Annual State tours will also be held.

IMPORTERS TO FORM ORGANIZATION.

Initiatory steps for the formation of the Automobile Importers' Society were taken at a meeting held Tuesday afternoon, April 23, at the clubhouse of the Automobile Club of America, New York City. The meeting was held in conjunction with the show committee and officers of the Automobile Club of America, and the show situation was discussed, after which the importers held a session of their own. In attendance were A. Massenat (Panhard), Sidney Breese (Westinghouse), Paul Lacroix (Renault), Percy Owen (Bianchi), G. R. Rheims (C. G. V.), A. C. Newbauer (Delaunay-Belleville), W. H. Bernard (Delahaye and Pilain), Arthur Waterman (Gobron-Brillie), A. M. Thackara (Westinghouse). Letters in favor of the movement were also received from Robert Fulton, of the Mercedes Import Company, and H. C. Cryder, of Cryder & Co. The Automobile Club was represented by President Colgate Hoyt, Secretary S. M. Butler, and the show committee, consisting of Col. George Moore Smith, chairman, Alan R. Hawley, Winthrop E. Scarritt and Geo. F. Chamberlain.

A call was issued inviting all independent automobile importers to another meeting to be held at the same place, Friday afternoon, April 26, when it is expected to permanently organize.

ITALIANS VICTORIOUS IN TARGA FLORIO.

Fiat was victorious in the opening round of the great European racing tournament, when Nazzaro captured the Targa Florio last Sunday on a wild mountainous circuit in Sicily, and Lancia, the eternal second, lived up to his reputation. The race was three times round the most difficult circuit in Europe, the number of sharp turns on each round being about one thousand, total distance being 279.6 miles. Of the fifty-four cars entered for the event, forty-five were sent away at intervals of one minute, Pilain, taking the lead followed by Benz and Darracq. Four European nations were represented by twenty important firms, the drivers including such well-known figures as Lancia, Wagner, Duray, Gabriel, Nazzaro and Hanriot. Albert Clément, who was engaged to pilot a Bayard-Clément machine, was unable to compete owing to the French military authorities refusing to give him leave of absence. After a keenly contested race, rendered still more exciting by the heavy rain which had made the mountain roads slippery, Nazzaro secured first position in 8:17. Lancia, also on a Fiat, finished eight minutes later, and Fabry on an Itala was third. Last year the Targa Florio was won by Cagno on an Itala.

NEW ENGLAND SECTION BLUE BOOK READY.

The New England section of The Automobile Official A. A. A. 1907 Blue Book has just been published. It is a handsome volume of 534 pages covering the best and most popular touring routes in the New England States with a completeness and exactness previously unattained. For 1907 the Blue Book is divided into three convenient-sized volumes, together giving an increase of about 50 per cent. over the single volume of last year. Sections 1 and 3, now in progress of preparation, will deal respectively with New York State and the West, and with New Jersey, Pennsylvania, the South and the West.

The New England book is prefaced by a special section giving the Metropolitan district, Shore Line, and Hudson River connections into New England, the return and connecting routes being covered by the complete sections in the same volume. Altogether, 17,000 miles of road are described and covered almost entirely by marginal maps. Among the entirely new features are general maps covering the entire country in miniature, the special purpose of which is to show the relation of one route to another—in other words to show at a glance how the different marginal maps in the body of the book meet and connect with the route system of the volume as a whole.

For the first time an index of principal trunk lines has been provided, outlining the through routes along the principal courses of road travel in New England. The index of places has been materially enlarged and made more definite and useful. A chart of automobile laws in condensed form occupies three pages of the book, giving the requisite information on registration, fees, numbers, lamps and speed laws for the New England and Middle States. Other tables give the essential facts of the different boat lines, their landings, time of departure from principal ports, and freight rates for the Hudson River steamboats, the steamships on the New England coast, as well as those connecting New York with the Atlantic ports and the West Indies. There is valuable information on European custom duties, freights, regulations, and laws in all the European countries generally visited by American tourists, arranged in the most convenient manner.

Altogether there are 285 routes, covering 17,469 miles of roads, 137 route maps, 19 full-page maps, 71 city maps, and two double-page maps. The volume which is elegantly produced and strongly bound in genuine leather, is listed at \$2.50 prepaid, from the Class Journal Company, publishers of THE AUTOMOBILE, Flatiron Building, New York City.

ANOTHER NEW YORK-BOSTON AEROCAR RUN.

BOSTON, April 23.—An unusual incident marred the New York-Boston non-stop effort of A. E. Robbins with the same air-cooled Aerocar which he successfully drove between the two cities at the time of the Boston show in March. Starting from New York City at 1:15 A.M., excellent time was made until within a few miles of Bridgeport, Conn. At this point the spark throttle failed to do its function, owing to the loosening of a set screw, and the engine came to an exasperating stop. Soon making the repair, Mr. Robbins restarted the engine, which worked beautifully thereafter the balance of the run, which terminated at 5 P.M. at the Boston Aerocar agency. Air-cooled non-stops are infrequent, and to-day's run was noteworthy. Besides the driver, there were George Van Cleve and two observers as passengers.

MEMORIAL DAY RACE MEET AT BOSTON.

BOSTON, April 22.—Boston is to have an automobile race meeting this spring after all. For a time it looked as if the Bay State Association would give up its annual custom of holding a meeting at the Readville track, but after it was announced that the Worcester club would abandon its hill climb, the pressure for some sort of a competitive event became so great that the racing committee of the Bay State Association, at its meeting this week, voted to hold a series of races on Memorial Day at Readville. The committee consists of President L. R. Spere, Charles E. Fay and F. A. Hinchcliffe.

SUBSTITUTES ACTIVE IN AUTOMOBILE OILS.

Success in any business necessarily brings the substitutor and the imitator. Up to this year the substitutor has not been much in evidence in the automobile business, but recently he appears to have become active in the oil trade. Owing to the fact that automobile owners have become better educated in the use of lubricants during the past year, legitimate manufacturers have built up big businesses in particular brands of oil, with the result that imitators have become numerous. Only last week, the Columbia Lubricants Company, of New York, which has suffered considerably at the hands of firms imitating its trade mark, procured an injunction in the United States Circuit Court for the northern district of Ohio, restraining the Atlas Oil Company of Cleveland from the use of the word "Monogram" to designate certain lubricants sold by them. The bill alleges that the plaintiff has built up a large and profitable business on account of the excellent quality of their goods, which would probably have continued to be a source of great profit were it not for the acts of infringement and unfair competition charged to have been committed by the offending firm.

A lubricant known as "Panhard" oil, on the market for several years, has established a good reputation. The oil was named when the Panhard car was first prominent in racing. The fact that the oil was found particularly applicable to the Panhard machine and was used by one of the racing cars of that make led the manufacturer, George A. Haws, to designate it as "Panhard Oil," meaning an oil especially adapted to engines of the Panhard type. As a claim of the quality of the oil the firm designated it as "The oil that will not char." That was in 1904. Recently another oil concern secured a letter from the local agency of the Panhard car, authorizing it to use the name "Panhard," and it is now marketing "Panhard Oil" and it is claimed profiting by the extensive advertising and reputation which the "Panhard Oil" manufactured by George A. Haws has built up.

In Philadelphia, Chas. F. Kellom & Company manufactures a lubricant known as "Invader" oil, and as such it is known all over the country. Recently the firm has heard from various parts of the country that other concerns were selling oil under the name of "Invader Oil." In one case when a salesman for the imitator called on a regular customer of Kellom & Company and was told that they intended to place an order for "Invader" oil he unblushingly stated that his firm made "Invader" oil for Kellom & Company and could fill the order at once.

These are a few samples of what the legitimate concerns in the automobile oil business are subjected to, and owners of cars who have been accustomed to using certain oils will find it to their advantage to be positive that the oil they are buying is the oil they intend it should be.

The following are the names of principal firms making automobile oils and the names of the oils which they market:

Columbia Lubricants Company,	Monogram oils
Fiske Bros. Refining Company,	Lubroleine
Harrington Lubricant Company,	Harrington oils
A. W. Harris Oil Company,	Harris oils
Havemeyer Oil Company,	Havoline oils
George A. Haws,	Panhard oils
Chas. F. Kellom & Company,	Invader oils
Wm. P. Miller's Sons,	Panolite
N. Y. & N. J. Lubricant Company,	Non-Fluid oils
Penn Petroleum Company,	Pennsylvania oils
W. C. Robinson & Company,	Autoline
Orlando W. Young,	Young's oils
Vacuum Oil Company,	Mobiloil
Valvoline Oil Company,	Valvoline

Philadelphia.—A new local organization of motorcyclists—the Pennsylvania Motorcycle Club—was launched in this city last week through the efforts of George W. Morley. Temporary quarters have been secured at 262 North Broad street, and a permanent organization will be perfected during the present week.

STODDARD-DAYTON, FIRST OF THE 1908 SIX-CYLINDERS,

ADVANCE MODEL OF THE STODDARD-DAYTON.

In quite striking contrast with the methods of but a few years back is the present-day manner of taking time by the forelock practiced by the automobile manufacturer. Then it was a struggle to get new models out in time for the January show, and more often than not they were only finished a few hours before, or were sent incomplete. Now the makers are patterning after those newspapers whose evening editions are on the streets at 7 A.M., so that though it is yet but April, and the season is not in full swing, 1908 models are beginning to appear. One of the first to be uncovered is the six-cylinder Stoddard-Dayton shown by the accompanying photograph. It is to be a 50-60-horsepower, seven-passenger car, with a 128-inch wheelbase and 36-inch wheels. One of the features of the power plant will be the use of duplicate ignition systems, one of which will employ the Bosch magneto. All on, the car will weigh 3,500 pounds, and no doubt will be a worthy addition to the Stoddard-Dayton line.

AN M. D.'S UNUSUAL RECORD IN A MAXWELL.

Not many autoists can point to a mileage such as Dr. Hess—a well-known ministrator to the ills of humanity on a part of the Pacific Coast—has rolled up in his Maxwell within the past year or so. Even more remarkable than the fact that he has driven his Maxwell Tourabout 16,000 miles in that period, is his achievement of making 12,000 miles on a single set of tires, which speaks well for both car and driver. Dr. Hess considers the automobile an indispensable adjunct to every up-to-date physician's outfit, not alone on the score of convenience, but that of economy as well, for on occasion he was compelled to charter a special train to reach a patient in a remote part of his district before becoming an autoist. The accompanying photograph shows the doctor in his 1906 Maxwell, and he has already placed his order for a 1907 model of the same make.

DR. HESS IN HIS RECORD-BREAKING MAXWELL.

RECENT TRADE DOINGS AT AKRON.

AKRON, O., April 22.—The B. F. Goodrich Company, largely on account of the growth in its tire trade, expects to begin work on a new five-story addition within two weeks for factory purposes. The building will be devoted to other manufacturing in addition to tires also. The company is also arranging to construct at the same time an immense office building which will be five stories high and 125 feet long by 50 feet wide. This will be devoted to office work solely, and will be one of the largest office buildings in the country. The company is now employing 2,700 people. Both buildings will be constructed of fireproof reinforced cement similar to the additions constructed last year.

It was announced last week that the International Harvester Company, with headquarters at Chicago, will begin the manufacture of farmers' auto wagons in the plant here that was acquired from the Aultman & Miller Company after that concern's failure. Although the real intentions of the company are kept a secret here, it is said on excellent authority that such is the intention. The company will also make a wagon suitable for milk dealers. It has been making a number at Chicago, and it has been found that the wagons take well.

BOSTON BRANCH OF THE H. H. FRANKLIN MFG. CO.

The new store of the air-cooled Franklin is located at 671 Boylston street, in the center of the local trade.

GOOD ADVICE BY AN AUTO CLUB PRESIDENT.

Charles J. Swain, president of the Quaker City Motor Club, Philadelphia, gives the following advice in the course of an article on "Courtesy on the Highway":

"I would lay special stress upon consideration for the farmer. The use of the road is to him a necessity. Through him largely it is maintained. If for no other reason, it were policy to secure his good will. The harboring in his mind of an injury, real or fancied, cannot but incur his enmity, and he has much to forbear at best. To sum up the whole situation, the motorist on the road can ill afford, for the sake of the sport, to make a single bad friend by any act of omission or commission."

BARNEY OLDFIELD AND HIS GREEN DRAGON.

At San Diego, Cal., on Sunday last, Barney Oldfield drove his Peerless Green Dragon a mile in 54 seconds, which is one second under the circular track record held jointly by himself and Walter Christie. A kick from the starting crank had given Oldfield a bruised arm, but did not prevent him from appearing before the large crowd. A 50-mile race was won by A. B. Daniels with a six-cylinder Stevens-Duryea, his time for the distance being 1 h. 1 min. 20 3-5 sec., lowering the previous mark for stock cars. A 50-horsepower Haynes was second, and a punctured tire spoiled whatever chance it had of giving the winner a harder tussle.

COACHING RUNNERS WITH A COLUMBIA TOURING CAR.

Coach Crooks of Columbia University directs the practice of his athletes with up-to-date methods.

SPRING AUTO SHOW FOR NEW ENGLAND.

SPRINGFIELD, MASS., April 22.—There is every indication of Springfield's first automobile and power boat show being a success. May 25 and June 1 have been fixed as the opening and the closing days, and the location selected is Hampden Park. Here a huge waterproof tent will be erected, divided into nearly eighty stands, each one having accommodation for one car. Exhibition space costs \$30 for the side stands and \$40 for the center positions. In the way of side attractions there will be races on the mile and half mile track, hill climbing contests and motor boat races on the river adjoining the park, for all of which events valuable prizes will be offered. The general management of the show is in the hands of William E. Dobbins, but a committee from the Automobile Club of Springfield has been appointed to co-operate in the attractions.

RENAULT RACING RUNABOUTS FOR AMERICA.

At the suggestion of W. K. Vanderbilt, Jr., the Renault firm has decided to construct fifteen special racing runabouts to develop over sixty horsepower, and attain a speed of seventy-five miles an hour. Ten of these have been reserved for Mr. Vanderbilt and his friends, and five are still for sale. The cars will be similar to the racer with which Szisz won the French Grand Prix last year, and will have two-seated racing body.

MISS JULIA SANDERSON TAKES A SPIN IN HER AEROCAR.

This popular actress, who has recently entered vaudeville, drives daily with her mother, who occupies the tonneau.

R. W. HEY, WHO WILL PILOT THE LONG-DISTANCE LAMBERT.

TAKING THE LONGEST WAY ROUND.

Rather a unique trip is about to be undertaken by Rodney Wellington Hey, late of Bozeman, Mont., but who for the next year or more will circulate around the borders of the United States in a Lambert friction-driven car. The start will be made June 1 from New York City on what may well be termed the longest continuous American trip possible, as the boundary line is not to be overstepped at any place. The route, as mapped out, includes the Atlantic Coast line to Florida as the first stretch, then around the Gulf along the edges of Florida, Alabama, Mississippi, Louisiana and Texas. At the end of the coast line of the latter State the first step in land will be taken after many thousand miles of coastline, and even at that, the change will merely be from ocean to river for a considerable part of the distance, as the Rio Grande will be followed, and again further west the Colorado will be met and followed part way to its source, where it crosses the southern boundary of California.

From there on there will be another long stretch of seacoast along the Pacific until Seattle is reached. At the latter place the longest installment of inland travel on the entire journey will be undertaken, following the line of the Canadian boundary eastward until the shores of Lake Superior are met, then down along Lake Michigan to Chicago, from which point the trip east to New York will still be continued as closely as possible to the Canadian border. In addition to forming one of the longest and most arduous tests to which a car has been put, this twenty-thousand-mile trip is also expected to constitute a record in other respects, as no time is to be lost unnecessarily, only brief stops being made in the larger cities along the route. Mr. Hey will be accompanied by a mechanic, and does not anticipate meeting any difficulties that cannot be overcome by grit and a determination to get through in spite of every obstacle.

BUCKEYE MFG. CO.'S FACTORY, WHERE THE LAMBERT IS MADE.

SUCCESS OF A PRIVATE SHOW IN ROCHESTER.

If you cannot get anyone to help you hold a show, why hold one yourself and show the other fellows how to do it. Such are the sentiments of A. M. Zimbrich, of Rochester, N. Y., and that they are well-founded was recently demonstrated by his carrying them into effect with no uncertain result. Rochester is a busy automobiling center, and Mr. Zimbrich thought it would be only in keeping with its dignity as such to hold a show of its own. He tried to interest the other dealers in the city, but they were not enthusiastic; so, nothing daunted, he went at it himself.

The new establishment, at 45-49 South avenue, Rochester, afforded an excellent place to hold it. Music was provided and souvenirs distributed, and the event was liberally advertised in the local papers. The result far more than exceeded expectations. The salesrooms were filled to overflowing every afternoon and evening, and a number of sales could be traced directly to the holding of the show, besides which a great many people were interested who could not have been met in any other way. Mr. Zimbrich is exclusive agent for the Stoddard-Dayton, Maxwell and Dolson lines, and makes an excellent showing of them, as will be apparent from the accompanying photograph of the interior of his establishment. Judging from the remarkable success which attended his efforts in the show line, there appears to be no reason why any dealer similarly situated should not do likewise.

A. M. ZIMBRICH'S AUTO SHOW AT ROCHESTER.

ANOTHER FACTORY FOR GRAND RAPIDS.

GRAND RAPIDS, MICH., April 22.—A. C. Menges, formerly of the Harrison Motor Company, is planning to bring out a machine of his own design in the near future, from which it is thought that Grand Rapids will, before long, become the home of another automobile factory. The car is to have several special features, not the least interesting of which is to be a hydraulic self-starting device; it is to be high-powered, and will tip the scales somewhere in the neighborhood of 2,700 pounds complete, listing at \$5,000. The company is to be capitalized at \$500,000, and expects to undertake the work of getting its car on the market in the near future—probably in time for the Fall shows.

A DELAWARE CITY'S COMMERCIAL AUTOING.

WILMINGTON, DEL., April 20.—The Delaware Auto Storage and Repair Company, which has a large garage at Eleventh and West streets, has added a carryall to its equipment, a "seeing Wilmington" vehicle, which has become quite popular.

The Dragon Run Dairy Company is using an automobile in connection with its milk and cream business in the city, and other interests will no doubt join the ranks in the near future.

STRATTON TO MANAGE TRADE ASSOCIATION.

Owing to the great amount of detail work involved in the management of the New York Automobile Trade Association and the fact that the officers of the association have so many other demands upon their time that they are unable to devote any attention to the business of the latter, the need of an executive head for the organization has been felt for more than a year past. Ezra V. Stratton, whose portrait is published herewith, has been appointed to the position with the title of general manager and will act as the executive head of the association so far as the general run of business is concerned, no change being made in the personnel of the officers on this account. Though previously not directly connected with the automobile industry, Mr.

EZRA V. STRATTON.

Stratton has a wide acquaintance among the trade, gained in his capacity as freight agent for the Seaboard Air Line, where he attended to most of the automobile shipments made to the South for the Florida races annually.

E. R. THOMAS TO MAKE MOTOR CABS.

BUFFALO, N. Y., April 22.—The making of motor cabs and town cars on a large scale is the latest announcement from the E. R. Thomas Motor Company. The plans for the making and marketing of these cars have been under consideration for over a year. During that time Gustave Chedru, head of the foreign engineering department of the company, has been conducting investigations in Paris.

Details of the construction of the new motor cabs will not be given out, according to the present plans of the Thomas company, for several months, but a general description would show that the car has a four-cylinder water-cooled motor, shaft drive, a three forward speed and reverse transmission and a wheelbase of 100 inches. The greatest saving in weight comes in the motor, which, because of the ultra advanced ideas used in its construction, will not weigh, approximately, more than half what the present day motors of about the same horsepower do.

ALBANY CLUB TO HAVE A ROAD RACE.

ALBANY, N. Y., April 24.—The Albany Automobile Club is up and doing. In addition to its annual run through two or three States, it now proposes to have a road race of its own, and has applied for and secured from the county supervisors permission to close the "River road" from Corning's farm, just south of Albany to Selkirk, in the town of Bethlehem to the southward, the "old stone road" from Selkirk to Becker's Corners, and the road back to point of starting, on the afternoon of September 14, between 3 and 6 p.m. The sheriff was authorized to appoint deputy sheriffs to patrol the course. They will be paid by the club.

The Saxe bill, to permit the formation of companies to insure motor vehicles, is now before Governor Hughes, and will probably be signed this week.

ABOUT THE MOTOR FUEL PROBLEM.

Although the production of crude petroleum in America is making enormous strides every year, the bulk of this comes from new territories, which yield heavy oils containing little or no spirit, says *The Engineer*. In fact, the fields which have in the past supplied the world with petroleum spirit and high-class illuminating oils are, it is said, failing, so much so that the center of production is no longer in the Eastern States, but lies equally between the Gulf States and California.

A QUAKER GIRL WHO DEMONSTRATES.

PHILADELPHIA, April 22.—A bright and pretty Quaker girl, Miss Vera Brewster, has opened the way for a feminine invasion of a field of endeavor hitherto monopolized by the male biped—demonstrating an automobile. Miss Brewster last week signed with the Foss-Hughes Motor Car Company here to demonstrate and sell the Baker electric car, which that firm represents in Philadelphia in connection with the Pierce and Cadillac.

Miss Brewster's personality is most charming, and when interviewed by THE AUTOMOBILE representative gave her reasons for "taking up men's work," as some of the local dailies put it. "Why not?" she said. "The occupation requires no special exercise of muscular power. To keep cool; to keep one's eyes open—those are sufficient. And the work is delightful to me. As for learning how to operate an electric car—this car"—and she patted the handsomely upholstered seat beside her—"it is nothing. Any woman with a little determination and an average amount of brains can master it in a day. No; I have no special taste for mechanics. Indeed, my folks had other plans for me. I was educated in a convent in Cincinnati, my birthplace, and afterward attended Mmes. Thavenet and Taylor's 'finishing' school at Neuilly, a Parisian suburb. Then I acquired the higher education fever and prepared for Bryn Mawr. When ready to enter that institution of learning the close application to my studies had so undermined my health that I was compelled to abandon the project. On my recovery I took a course of interior artistic decorating, but again the confinement indoors sickened me, and that I also abandoned. Finally, the necessity of taking up some outdoor occupation forced itself upon me, and after giving the matter no little thought I decided to be the pioneer in a new feminine profession. I argued that if women could be convinced of the ease with which automobiles—electric cars especially—can be operated, many of them would become purchasers. I presented my plan to Messrs. Foss and Hughes, and within a very short time became a qualified demonstrator. While I work hard and the hours are long, the work is charming and healthful.

"I have already discovered that many women who would hesitate at taking lessons from a man demonstrator will eagerly embrace the opportunity of acquiring automobile knowledge from a woman. Hence, I feel that by applying myself to this work and acquiring a knowledge of the car, I can make myself doubly valuable to my employers.

"Philadelphia, with its level asphalt streets, is admirably adapted to the small electric car, and I am firmly convinced that I can arouse among Philadelphia women a desire to own and run such cars. Cleveland has upwards of 200 of these small machines, many of them operated by women. Boston, Washington, Chicago and New York are not far behind. I may be instrumental in getting this city interested. That is what I am working for. You will have to excuse me now. Here comes my 'prospect.'"

WALTER BAKER TOURING IN FLORIDA WITH HIS PEERLESS.

EXTERIOR OF THE MORRIS GARAGE AT WESTCHESTER, N. Y.

THE INCREASING LIST OF GARAGES.

Dave H. Morris' Model Fireproof Garage.

Up to a certain point the adaptation of the private stable for garage purposes satisfies all requirements, but it is not long before the enthusiastic autoist finds that such a plan of housing his car has serious drawbacks, not the least of which is the ever-present danger of fire. The majority of stables are of frame construction, and even where stone or brick are employed for the walls, the interior is so generously furnished with combustible material as to render the use of such a building a constant menace. Autoists who have given the subject any consideration have found the best solution in a building specially planned for the purpose, an effective combination both from the artistic and utilitarian point of view being that of concrete and terra-cotta as employed in the model fireproof garage recently erected for Dave H. Morris, at Westchester, N. Y. The attractive appearance of the building is evident from the accompanying photograph, while a second view shows its spacious interior. This measures 17 by 26 feet and is entirely devoted to the cars. There is storage space for two large cars besides a drain table for washing. Back of this main room there are two smaller rooms, one fitted as a workshop and the other housing the heating apparatus for the building. A steel tank, encased in concrete and buried some distance from the garage, stores the fuel supply. On the upper floor are located the chauffeur's quarters. The plans were executed by the New Century Contracting Co., New York City.

Modern Garage Close to Harvard College.

CAMBRIDGE, MASS., April 22.—The Harvard Automobile Company has just moved into its new garage on Quincy Square. The location is very favorable, being opposite the college yard and near the large dormitories on Mt. Auburn street. Last year the company occupied a small wooden building on the same site, but the demand was so great that it was decided to erect a more suitable structure.

The new garage has a frontage of 125 feet on Quincy Square and is 200 feet deep; it is two stories high, and built of reinforced concrete, fireproof throughout. On the first floor are the main storage room, the waiting rooms and lavatories, and an office overlooking the door by which all cars must enter and leave. Above, the space is given over to storage and repairs. The machine shop is equipped with lathes, planer, shaper, drill press and portable drills, and is in charge of competent mechanics. An air compressor is provided for cleaning and inflating tires. Heating is by steam, with boilers in a separate building. The total capacity is from 160 to 200 cars.

Many Harvard students own automobiles, and quite a number have foreign cars. A look through the garage showed two Panhards, a Brasier and a Fiat. The manager is Roy Faye, who

is well known among Boston automobilists. The company has the agency for the Matheson and Atlas cars, and in addition does a large renting and supply business.

Work Resumed on Portsmouth Garage.

PORTSMOUTH, N. H., April 22.—Work has just been resumed on the new garage here, after being suspended for several months. The exterior of the building is already completed, but the interior—concrete floor, machine shop, offices, lavatories, waiting rooms—will not be ready for occupancy before about the first of June.

The Granite State Fire Insurance Company, which owns the property, has leased it for a term of years to H. L. Beacham, proprietor of a livery stable in this city. Besides being one of the most commodious, the lessee promises that it will also be one of the finest and most thoroughly up-to-date in New England.

The poor accommodations afforded automobile parties in the care and stabling of their cars here, during the last two seasons, have caused loud complaints by tourist and summer resident alike, and, no doubt, the erection of so fine a garage will be hailed with satisfaction by all who patronize it. The Granite State Fire Insurance Company is sparing no expense in the construction of the building, which will involve an expenditure of at least \$17,000.

New Link Between Philadelphia and the Water Gap.

W. H. Pearce, at one time a well-known bicycle racer, and later a salesman and demonstrator for the Philadelphia branch of Thomas B. Jeffery & Co., has just opened a modern garage at Bangor, Pa., having been granted the exclusive agency for the Rambler cars in Northampton County, Pa. The establishment will be known as the Bangor Auto Garage, and will have a first-class equipment of power-driven machine tools with every facility for undertaking all kinds of repairs, Mr. Pearce himself being an experienced machinist. Something like \$1,500 have been spent on fitting up this part of the garage alone. In addition to being located on the direct line between Philadelphia and the Delaware Water Gap, one of the most popular summer resorts in that part of the country, the new garage at Bangor is also the last stopping place after leaving Bethlehem, Pa., for Scranton, or Wilkes-barre. That immediate success has rewarded the efforts of Mr. Pearce may be judged from the fact that he has already disposed of something like four carloads of Ramblers, all for early delivery, and some of which are now coming through. During March he averaged three or four cars a week.

HOW THE INTERIOR OF THE MORRIS GARAGE LOOKS.

Two New Garages Open in Toledo.

TOLEDO, O., April 22.—Last week saw the opening of two new garages in this city. The Toledo Motor Car Company now occupies and conducts the Coliseum garage at the corner of Bancroft street and Ashland avenue in connection with its garage on Madison avenue. The Coliseum garage is the largest in the city and embodies the private stall idea as well as all the other late ideas along garage lines.

The Craig-Toledo Automobile Company, which is manufacturing an automobile by that name at Dundee, Mich., has leased the White garage on Madison avenue. This garage was built for the White company by the Spitzers, but since the entire output of the White factory has been sold the garage was of little use and that company had previously not operated in this city.

Springfield to Have an All-Night Garage.

SPRINGFIELD, MASS., April 22.—What is known as the Bemis property on Taylor street has recently been acquired by Theodore Geisel. The lot is 127 feet deep, 144 feet on the rear line and 126 feet street front, with a 20-foot passageway on each side. It will be utilized by the Geisel Automobile Company, of this city, for a modern garage, the plans for which are already completed. At present this will only occupy one corner of the property measuring 55 feet front by 127 deep. The roof will be trussed so there will be no posts to obstruct the floor. Later on the building will be extended to cover the entire property. As it is situated close to the leading hotels and just off the main street, transient trade will be catered to, and mechanics kept on duty all day and night. The contract for the construction of the building, which will be of brick and concrete, has already been awarded. The front will be largely composed of plate-glass windows.

Modern Garage Between Cleveland and Toledo.

ELYRIA, O., April 22.—It will be of interest to autoists generally to learn that another modern station has been completed on the main route between Chicago and New York, and to northern Ohio autoists particularly, as the new Leonard garage in this city is said to be the best between Cleveland and Toledo. The new building is situated on Broad street one block north of Fremont and extends north. It measures 117 feet in depth, and provides about 10,000 square feet of floor space. A modern and completely equipped machine shop capable of executing all kinds of repairs is maintained and an up-to-date service in every respect furnished. H. M. Leonard is the owner, and the establishment is known as Leonard's Auto Station.

New Garages Springing Up in the Windy City.

CHICAGO, April 22.—Within the past few weeks there has been unusual activity in the fitting up of new garages in anticipation of the coming season's business. One of these, known as the Chicago Auto Garage, which has located at 3210 N. Clark street, has been granted the sub-agency for the Reo and Premier cars, in addition to which it will carry on a general garage business. A few blocks south another general garage and salesroom has been opened at 3096 N. Clark street. This is owned by M. L. Barrett, for whom the building was specially erected. It measures 50 by 116 feet and is modernly equipped throughout.

IN AND ABOUT THE GARAGES.

Savannah, Ga.—A garage and repair shop has been opened at 314 St. Julian street, west, by F. C. Kramer and G. W. Wroten, who have recently formed a partnership.

Kansas City, Mo.—A new garage has been opened here by the Kaw Valley Auto Company, agents for the Premier, and the Mason Car Sales Company, at 3131 Main street.

Des Moines, Ia.—A garage has been opened by the Goodwin Automobile Company, which has taken the agency for the

Rambler and Mason cars. The building is located at 612-616 Mulberry street.

Champaign, Ill.—The Champaign Automobile Company, of this city, has been incorporated to establish a garage. J. C. Richmond and Manford Savage are the interested parties.

Huntsville, Ala.—An up-to-date garage is to be established by the Huntsville Motor Car Company, which has leased for a term of years a new building in course of erection on Gallatin street. The building is of concrete and iron and brick.

San Francisco, Cal.—Under the title of the Mission Garage, a large establishment has been opened to do a general garage business at 611 Valencia street, between Seventeenth and Eighteenth streets, by D'Arcy, Scott & Co. It is one of the most modern establishments of its kind that the city can boast.

Grand Rapids, Mich.—With the completion of the establishment of the Luce-Banks Company, on North Division street, Grand Rapids may well lay claim to growing prominence as an automobiling center, for this makes her eighth garage, and some of them are establishments of imposing proportions for the size of the city.

Montclair, N. J.—Under the management of W. H. Higgins, Jr., the garage formerly operated by the Montclair Auto Station has been reopened, and will be run by a new company composed of Montclair business men; the members are C. D. Vreeland, W. H. Higgins and W. H. Higgins, Jr., all of upper Montclair. The company intends to sell machines as well as storing and repairing them, and expects to obtain the agency for a popular car in the near future.

Crown Point, Ind.—That road and street improvement and automobiling go hand in hand was never better illustrated than in this part of the State of Indiana, where, as the result of general attention to improvement on the part of the authorities, C. M. Baker, who is the local agent for the Rambler cars at this place, reports that interest in automobiling has increased considerably. The outlook for a successful season was never better, says Mr. Baker, much of it due to the prospect of better roads.

TOOL FOR MOUNTING SIDE CHAINS.

Dismounting and remounting the side chains of a big car is not the cleanest of jobs, nor the easiest if you are single handed. If the chain is at all tight, the operation of bringing the two ends of the chain together in order to pass the bolt through is one that requires some patience. To simplify this task a French

chauffeur has devised a simple tool, the illustration of which is reproduced below from *Omnia*. It consists of three metal arms, two of which, B and C, have their extremity curved to hook around the links of the chain. A is the lever operating the tool. The arm C is hinged to the extremity of the lever A.

FRENCH TOOL FOR MOUNTING CHAINS.

The arm B has a stud riveted into its end, allowing it to be placed in any of the holes drilled in the lever, thus giving a longer or shorter range of action, as required. It will be noticed that the lever is slightly curved, this being necessary in order that it may remain in position when the tool is in use, as shown on the lower sketch. Any number of holes may be drilled in the lever, but they should always be in the curve. The tool is one that any mechanic can make, and the labor spent in constructing it will be amply repaid by the value of the instrument in every-day work. It will certainly prove a great time saver.

BRIEF ITEMS OF NEWS AND TRADE MISCELLANY

All the 300 Frontenac touring cars to be made by the Abendroth & Root Manufacturing Company, of Newburgh, during 1907, will be equipped with Trauf-fault-Hartford shock absorbers.

Owing to increase of business, the Tut-hill Spring Company, of Chicago, has decided to call a meeting of stockholders to vote upon the question of increasing the capital stock from \$50,000 to \$100,000.

The old-established carriage building firm of S. C. Pease & Sons, Merrimac, Mass., has entered the automobile field and is now prepared to do a big business in automobile bodies, particularly in limousine and landaulette styles. All body repair work is undertaken.

The F. B. Stearns Company of Cleveland a few days ago delivered to former Governor Myron T. Herrick of Ohio one of the finest machines ever turned out of the factory. It is a large seven-passenger Pullman body touring car, handsomely trimmed and equipped.

So many applications for work at the new Rainier factory at Saginaw having been received at the New York office, the company has made the announcement that such applications should be directed to James G. Heaslet, factory manager, 820 West Warren avenue, Detroit, where they will be given due consideration.

A. R. Bangs, who, since he retired from the Franklin agency in Boston, has been busy in his machine shop, promises the first public view of the completed Viking next month. The machine will have four cylinders, will develop 40-horsepower, will have bevel gear drive and 120-inch wheelbase. Selling price will be \$3,000.

Contracts involving an expenditure of \$100,000 have been let by Thomas H. Midgley, consulting engineer of the Rubber Goods Company, for a large addition to the plant of the Midgley Manufacturing Company, on Dublin avenue, Columbus, O. The present area of the plant, used for the construction of wheels, rims and other parts of automobiles, will be increased by more than two-thirds.

There is no mystery about starting a motor from the seat on the spark. The explanation is that so long as compression is held in a cylinder, the spark can be used to ignite the charge and start the motor. At St. Louis, the other day, it is reported that a Winton Type XIV was started from the seat on compression that had been held an entire week, as the result of perfect fitting cylinders, pistons and rings.

A man who has been a member of the American Automobile Association since it was launched, made a pat remark recently when he said that any motorist who does not join the national body is no better than a tax-dodger who enjoys the benefits of municipal work and shirks contributing his share. He has representation without taxation, and, similarly, all motorists share to some extent in the good work done by the A. A. A.

Indestructible steel wheels, made by the Turner & Fish Company, Chicago, are used on the somersault automobile in the thrilling feat at the Ringling

Brothers' circus. The landing of the car produces a crash of 9,000 pounds, the speed being equal to 42 miles an hour, and the car weighs 2,000 pounds, dropping in midair 30 feet after the somersault. The wheels were regular 16-gauge pleasure car wheels.

C. N. Sauerbach, the exclusive agent of the Mitchell Motor Car Company in Europe, will place his repair shop at the disposal of American tourists and those competing in the American Gold Cup Tour this coming season. Any spare parts of automobiles sent to the Mitchell Car Agency, 27 Rue d'Aboukir, Courbevoie, near Paris, France, will be taken care of and forwarded, upon request, to any individual owner of such parts. Mr. Sauerbach will also supply information which might interest foreign tourists.

The F. B. Stearns Company of Cleveland will increase the capacity of its factory on Euclid avenue by the addition of about 10,000 square feet of floor space the coming summer. Later additions will be made that will double the capacity. The company has ordered a number of German gear cutting machines, such as cannot be found in this country. Roy F. York, sales manager of this company, is now in San Francisco, and will go on up the coast to Seattle before returning to the home office.

At the annual meeting of the stockholders of the Joseph Dixon Crucible Company, of Jersey City, N. J., the old board, consisting of Edward F. C. Young, John A. Walker, Edward L. Young, William Murray, George T. Smith, Joseph D. Bedle and George E. Long, was unanimously re-elected. The board of directors re-elected the former officers, namely, E. F. C. Young, president; John A. Walker, vice-president and treasurer; George E. Long, secretary. Judge Joseph D. Bedle was also re-elected as counsel.

George K. Wheeler, sales manager for Columbus Electric, made by the Columbus Buggy Company, Columbus, O., has just finished one of the longest trips made by a sales manager, having since November 1, 1906, visited every city in the United States and personally looked over the situation as regards the possible market for electric carriages. At the present time the Columbus is represented in the majority of the cities of the United States. The factories are making large shipments daily to all portions of the country, and have recently put up an addition to the plant to take care of the increased automobile business.

Progress on the two Dragon racers which are being built for the Vanderbilt Cup race is being reported daily to the officers of the Dragon Automobile Company. According to these reports, it is apparent that the racing Dragons will be ready on schedule time, May 15, which is the date set for completion of tests on the finished engines. July 1 is the date arranged when cars will be running on the road, and the company is now giving considerable thought to the matter of drivers for these cars, but as yet no selections have been made. A special

building on the factory grounds has been set aside and is being prepared to be used solely for work on the racing cars.

The most noticeable feature of the past season, according to F. A. Babcock, president of the Babcock Electric Carriage Company, is the increase in the number of women who drive their own cars. The increase is probably more noticeable in the electric line than in gasoline or steam. There are no complications, there is no need of a chauffeur. Madame can wear her nicest and daintiest frocks, and she does not have to strain her voice to carry on a conversation with her companion. All these things appeal to a woman, and there is not a lady who ever rode in an automobile who has not hopes that some day she can sit at the wheel and drive her own car over the boulevards and through the parks.

COMING TRADE REMOVALS.

The Olds Motor Works has arranged to take over the agency of the Olds machine, which has been conducted by the Bailey Company on Prospect avenue, Cleveland, O., under the name of the Oldsmobile Company. The room on Euclid avenue recently vacated by the Aerocar Company has been secured and a complete sales room and repair shop will be established. The location is in the midst of the motor colony of the city.

The H. J. Koehler Sporting Goods Company has just executed a long lease for the premises at the northwest corner of Fifty-fourth street and Broadway, New York City, where the Buick agency will be carried on, the old establishment having been located a few blocks further down Broadway for several years past. In addition to this, branches are maintained at Newark, Paterson, Montclair, and East Orange, N. J., for the agencies of the Buick, Corbin and the Pope-Waverley electric cars.

Owing to the great increase in the demand for their specialties during the past year, both the Crown Battery Company and the Tire Safety Device Company, the former of which has been located at 47 Warren street, New York, and the latter at 208-14 West 124th street, will remove to a new factory at 992 Southern boulevard. With the added facilities installed in the new establishment, the plant will have a capacity four times greater than that previously enjoyed. C. R. Bissell is vice-president of the Crown Battery Company and general manager of the Tire Safety Device Company.

Another May 1 removal will be the shifting of the Diamond Rubber Company from its old quarters to new and more spacious surroundings in the new Motor Mart at 1876 Broadway. They have been finely fitted up under the direction of Theodore Wiegale of the home office, who has come on to assist H. J. Woodard, the New York branch manager. Ever since the beginning of the industry the Diamond Rubber Company has had a branch at 1717 Broadway, so that with its removal further up-

town a landmark will disappear. The New York headquarters, for many years at 78 Reade street, will be consolidated with the new uptown store.

Next week the New York branch of the Corbin Motor Vehicle Corporation will take up new quarters in a prominent location on New York's automobile row. It will occupy the northerly end of the big store in the building of the American Locomotive Auto Company, at 62d and 63d streets and Broadway, the latter concern maintaining a large salesroom for their American Berliet cars on the same floor. The old Corbin quarters at 1779 Broadway will be given up on May 1. The new establishment affords a plate glass frontage of 40 feet, so that the Corbin will be prominently displayed. In line with its well-established policy at branch houses, the Corbin company will maintain a complete repair department.

NEW AGENCIES ESTABLISHED.

One of the first active steps taken by the new management of the Acme Motor Car Company, of Reading, Pa., since its reorganization by H. M. Sternbergh, who is now its president, has been the appointment of Theodore E. Schultz as New York representative. Mr. Schultz's establishment is at 1843 Broadway.

Up to date the Forest City Motor Car Company of Massillon, O., manufacturers of the Jewel automobiles, has established no less than forty-one agencies throughout the country. In addition to locating in most of the principal cities from coast to coast, a large number of agents have also been appointed in smaller towns, as well as a general foreign agency at London, Eng.

A. E. Schwartz, the representative abroad for the American Motor Car Manufacturers' Association, has formed the American Auto Supply Company in Paris, with headquarters at 102 Rue la Boetie. It is expected that the place will become headquarters for Americans while in Paris, as Mr. Schwartz is well informed on foreign conditions, including licenses, passports, and similar necessities for travelers.

The Michigan Storage Battery Company, with main offices and works at Detroit, Mich., have just opened a New York branch at 2330 Broadway, near Eightieth street. Complete stocks will be carried at all times, in addition to which a thoroughly-equipped charging and repair station will be maintained. George S. Morrow has been appointed manager of the new branch house, and will be assisted by a number of expert battery men sent direct from the factory.

The Dupont Garage Company, having acquired the Washington branch of the Electric Vehicle Company, has become the agent in that territory for the Columbia cars, both electric and gasoline. The Rambler and Cleveland lines, formerly carried by one of the stockholders of the company, have been discontinued. In addition to its main establishment at 2020 M street, Northwest, the company will also continue its commercial branch in the old Panorama Building at Fifteenth street and Ohio avenue.

PERSONAL TRADE MENTION.

R. D. Aldrich has resigned his position as manager of the New York branch of the Rose Manufacturing Company to

become sales manager of the Twentieth Century Manufacturing Company, 19 Warren street, New York City.

A. H. Dorsey, who was formerly connected with the sales department of the Harry Fosdick Company of Boston, has been elected vice-president and general manager of the United Motor Car Company of Philadelphia, which is agent for the Thomas car in that city.

It has been erroneously stated that George C. John has severed his connection with the St. Louis Car Company, makers of the American Mors. It seems that while F. J. Pardee has been made sales manager and will remain in charge at the factory, Mr. John will continue his connection with the St. Louis company.

J. H. McDuffee, of the McDuffee Automobile Company of Chicago, which handles the Stoddard-Dayton, De Luxe and Kisselkar in the west, has gone to Arizona for several months respite from business. Mr. McDuffee has been in poor health for some time, and has been advised by his physicians to rough it for several months away from the haunts of civilization.

Frank S. Corlew has announced his resignation as vice-president and manager of sales of the Dragon Automobile Company of Philadelphia, to take effect May 1. Mr. Corlew will announce in a short time his plans in connection with the automobile business which he states will be of interest not only all over the country, but especially so to the New England trade.

F. G. Carrie, representing the Electric Vehicle Company of Hartford, Conn., will have headquarters in Havana, Cuba, for the next few weeks, where he will show and demonstrate the high and medium-powered Columbia gasoline cars and the Columbia electric victoria phaeton. Mr. Carrie for some time past has been connected with the New York branch of the Electric Vehicle Company.

In order to properly handle the increasing sales, President Horace Delisser, of the Ajax-Grieb Rubber Company, has appointed H. M. DeSilva and R. S. Ireland on the selling force for Ajax tires. Both men are well and favorably known in the trade, having for years been connected with the International Rubber Company. Mr. DeSilva will cover the western territory and Mr. Ireland will devote his attention to the southern trade.

A. L. Kull, for the past few years the well-known representative of the Wayne in New York City, and who lately formed the A. L. Kull Automobile Company, the present representative for the Dragon and Wayne cars, has succeeded Frank S. Corlew as sales manager for the Dragon Automobile Company. Mr. Kull is well known as one of the most active representatives in the automobile

trade, and has the reputation of being a "hustler" of the most advanced type, and the aggressive policy of the Dragon company will be kept up in every detail of the selling department.

RECENT TRADE PUBLICATIONS.

A chapter of accidents and facts are given in the neat folder issued by the Fisk Rubber Company, Chicopee Falls, Mass. The booklet presents extracts from daily papers of automobile accidents caused through tires which burst, and shows how they could have been avoided by the use of the Fisk. There is also a description of how to remove and attach a Fisk tire and an account of the various sundries handled.

Two new catalogues have just been sent forth from the Cadillac Motor Car Company's headquarters at Detroit, Mich. Models K and M are treated in one, and the four-cylinder Model G in the other. A feature of both publications is the excellent half-tone illustrations showing the various mechanical parts of the Cadillac. With the aid of these and the explicit text matter a good knowledge of the cars can be obtained. The booklets are excellently printed in two colors, and smartly bound.

As an elegant piece of designing and an example of skilled typography, the publication from the George N. Pierce Company is far ahead of the usual trade literature. It deals with the new factory just built for the Pierce Great Arrow at Buffalo, N. Y., on the Kahn system of reinforced concrete. This method of building gives a structure as substantial as though carved out of solid stone, fireproof, and possessing the granite-like qualities of concrete with the elasticity of steel. A large number of excellent illustrations show the building in course of construction and several full page illustrations give an idea of the tremendous area covered by the plant.

FAMOUS PRESSED STEEL PLANT.

Cleveland can boast one of the largest steel-pressing plants in the country, in the shape of the establishment of the Hydraulic Pressed Steel Company, Cleveland, which makes a specialty of automobile frames and stampings. It is claimed to be the first large plant of the kind especially erected for the purpose, and is, in consequence, equipped throughout with the most modern machinery for turning out work of this class, the main press-room measuring 80 by 200 feet. Some idea of the extent of the factory may be obtained from the accompanying photograph showing a view of it. The concern is backed by well-known Cleveland capitalists, and is managed by James H. Foster, who is also vice-president of the company. The sales end is in charge of Roger B. McMullen, formerly with the A. O. Smith Company.

FACTORY OF THE HYDRAULIC PRESSED STEEL COMPANY, CLEVELAND, O.

INFORMATION FOR AUTO USERS.

Presto Detachable Rim.—This is a device of that class of things mechanical which have the merit of using well tried and thoroughly proven details of construction. The rim carrying the shoe and tube is of the regular standard clincher construction to which is added a number of lugs on its under face. These

SECTIONAL VIEWS OF PRESTO RIM.

lugs are really nuts that are permanently screwed onto inwardly projecting flat headed bolts countersunk into the rim. There are from six to eight of these nut lugs, according to the size of the wheel. Permanently mounted on the wood felloe is a steel band and in this band are cut L-shaped slots agreeing in number with the rim lugs. These right angled slots have their stems running parallel with the rim sides, while the "foot" sections of the slots come out to one edge. It will be seen that this combination gives a series of bayonet clutches. The stems are slightly tapered toward their closed ends to give a wedging effect. At opposite points in the felloe are two spring plunger bolts that act as locks when the rim is in place, the rim having a series of holes extending around it to take these plungers at any point the rim may be put on. To remove a rim, withdraw the two plungers one a quarter turn to prevent them drawing back, move the detachable rim backward about one inch and then toward the operator. The act of replacing is obviously the reverse of the above. By actual demonstration the rim was taken off and fully replaced, time and again, in eight and nine seconds. It is not necessary to match a particular lug on the rim with a particular bayonet slot in the felloe, all these being interchangeable. To take care of this condition, as well as to permit either edge of the rim being started on, there are twice as many plunger holes in the rim as there are lugs. Further information regarding the device may be had from Presto Detachable Rim, 403 Lincoln Trust Bldg., Jersey City, N. J.

A Useful Connector.—The guaranty given with the O. K. Connector, as manufactured by the O. K. Connector Com-

O. K. BATTERY WIRE CONNECTOR.

pany, 51 Waldo street, Worcester, Mass., is that it will not wear out, and that it will show more amperes than others, because of it having a spring tension, making a positive contact. With this

simple little article, a sample of which may be obtained by mail for ten cents, there are no broken or loose connections, and no need for the use of pliers.

"Autoleum" Fireproof Gas Engine Oil.—Realizing the absolute necessity of a special grade of lubricating oil for each particular purpose, and no piece of machinery abounds in different requirements of lubrication more than the automobile, A. W. Chesterton & Company, 64 India street, Boston, Mass., make a specialty of different brands of their "Autoleum" oils for different uses. Particularly such as are required for the high temperatures of the air-cooled motors, also for water-cooled motors, beside "Autoleum" crankcase oils, lubricating greases and the like for both gas and steam engines. In addition, they carry a full line of lubricating accessories.

Automobile Goggles.—There are six distinct styles of automobile goggles manufactured by the Globe Optical Company, of Boston, Mass. All the different types are fitted with ground plano

GLOBE AUTOMOBILE GOGGLES.

lenses without focus or power. If desired, however, they can be ground to correspond with prescription of the wearer's glasses, thus avoiding the inconvenience of wearing both glasses and goggles. The lenses are also arranged to give extremely wide range of vision. In four of the styles this is accomplished by using lenses bent to conform with the curvature of the face. The others are of popular four-glass style. Smoke or amber-tint lenses, specially recommended because they protect the eyes from the glare of the sun and improve the acuity of the vision, are also supplied. The four-glass goggles have a patented arrangement for removing lenses. A type specially recommended for ladies is the collapsible, with silk, velvet or chenille binding, with a strap allowing variation of the distance between the eyes. All types are supplied complete in leather case.

Ferro Auto Marine Engines.—There are a number of original and distinctive features in the Ferro two-cycle auto marine engines built by the Ferro Machine and Foundry Company of Cleveland and 79

Cortlandt street, New York. They are made with one, two and three cylinders, and in sizes from 1 1/2 to 25 horsepower. The individual cylinders are made with a flange increasing from bottom up, carry no shaft bearings, have no joints under pressure, no water pipes or visible external connections. These features will be noted from the il-

FERRO TWO-CYCLE AUTO-MARINE ENGINE.

lustration. The pistons have four rings and double piston pin bearings, piston rings and cylinders being ground to an absolute fit. There is no bearing at upper end of connecting rod, the hollow piston pin being rigidly clamped to rock with it, thus giving increased strength and almost double bearing surface. Crank pin bearing cap at lower end is adjustable. Valves are large and adjustable, and there are no pipes to engine whatever. Water enters each cylinder jacket separately near exhaust by hidden branch passage leading directly from large main to pump. Two complete sets of hardened steel ball thrust bearings, one on forward and one on after end of crank shaft prevent any strains on cranks, connecting rods or pistons. Lubrication is assured by a battery of sight-feed valves supplied with oil from a pressure-feed reservoir. The Ferro quick-starting carbureter is of a special type, designed for marine service and conditions. By using the lever-operated compound throttle instant changes of speed can be obtained, varying from 150 to 900 revolutions. With all except the smallest engines the Ferro exhaust silencer is supplied, consisting of exhaust header and condenser silencer combined.

Rex Igniters.—In the 1907 type of Rex igniters, manufactured by the New England Motor Company, Lowell, Mass., a storage battery has been designed which is particularly adapted for ignition work. The grid is of such a form as to absolutely lock the active material in place

THE REX IGNITER.

and prevent it dropping out when in service. The plates are assembled in celluloid jars, each jar having a separate cover. By the use of separate covers, entirely insulated from one another, the charge is retained for an indefinite period. The connection which extends from

the inside of the cells to the outside is of such a design as to reduce corrosion to a minimum. As far as possible brass and nickel parts have been eliminated. All parts are manufactured by the company, thus making it possible to assure the quality of the product with much more certainty than if the work was undertaken by a number of independent firms.

New Weston Multimeter.—This instrument, produced by the Weston Electrical Instrument Company, of Waverly Park, Newark, N. J., is one which will serve the purposes of a direct current voltmeter, milli-voltmeter, ammeter, milliammeter, ohmmeter, ground detector and wheatstone bridge. The part of the multimeter designed to be used for the purposes mentioned is similar to the Weston portable direct-current instruments, but differs from the regular forms in that a special movable coil is employed in the multimeter. The calibrated scale of the instrument has 160 divisions,

WESTON MULTIMETER, WITH COVER RAISED.

with the zero placed at 10 divisions from the end, so that when the instrument is used as a galvanometer in connection with the bridge, both positive and negative deflections are observed. The wheatstone bridge, which forms part of the multimeter, consists of a rheostat with three groups of coils, adjusted respectively to units, tens and hundreds, aggregating 999 ohms, and a set of five ratio coils. Many novel features are embodied in its construction. All conductors and plug receptacles are placed under, instead of upon, the rubber top.

Puncture Proof Tire Filler.—"Elastro" is the title of a resilient compound for filling pneumatic tires, in order to do away with the possibility of punctures and other mishaps that may befall the tire, whether on a car, motorcycle or even a bicycle. It is a plastic substance injected into the tire while warm and in a liquid state by means of a pump or air compressor and special machinery designed for the purpose. The amount of pressure required is regulated by the weight of the car, so that a tire filled with Elastro lacks none of the features of the regulation pneumatic tire, but cannot flatten or collapse, remaining the same until either the shoe and tube, or both, are worn out. The nature of the compound is such that the makers guarantee it proof against heat and cold, and will, moreover, continue to give satisfactory service even though the tire be full of punctures or cuts. It is made by the Elastro Manufacturing

Company, Hartford, Conn., and it is the purpose of the latter to sell territorial rights for the exclusive use of the compound on a royalty basis, supplying the necessary machinery and equipment. Ernest Cady, manager of the agency department, is also located in Hartford, at 26 State street.

An Improved Spring.—Quite a novel and yet extremely simple method of improving the suspension of a car is being marketed by the Garden City Spring Works, 20th and Purple streets, Chicago.

NEW GARDEN CITY SPRING.

As will be plain from the illustration of the device, its installation calls for no change either in the frame or the hanger. Although shown in connection with a semi-elliptic spring, it is also equally applicable to the full elliptic type. Some of the advantages claimed for it are the reduction of the recoil or rebound by lengthening and softening the spring, so that the car will ride as easily with the driver alone as with the full complement of passengers. It is the invention of D. R. Close, and patents have been applied for.

Atwater-Kent Spark Generator.—While making its famous non-stop record of 6,000 miles last winter, the Thomas Flyer was also making a record performance for the Atwater-Kent spark generator with which it was equipped. Throughout the entire run it was unnecessary to give the spark generator any attention whatever, and the entire distance was made on a single set of six dry cells, which shows that the maker's claims for very largely reduced

THE ATWATER-KENT SPARK GENERATOR.

battery consumption are well-founded. As shown by the illustration picturing it herewith, the entire system with the exception of the batteries and plugs in the cylinders is comprised of a single, self-contained unit which forms a fitting

ornament for the dash of any car. There are no vibrators, commutators or moving wires, and every part of the system is immediately accessible for inspection without the necessity of leaving the seat. The spark maintains a constant value, regardless of the speed of the engine, which is a decided advantage for easy starting. Moreover, there is only one adjustment necessary, and the circuit is broken in but one place, so that but two platinum contacts comprise the entire wearing parts of the system. The engine may be started by pressing a button, and the driver is also enabled to test the running of each cylinder separately. The model shown is that for four-cylinder engines, but types are also made for three and six-cylinder engines. It is made by the Atwater-Kent Manufacturing Works, 116 North Sixth street, Philadelphia.

The Willet Carbureter.—Easy starting and ability to use low-grade fuel with the same facility as the most expensive are two attributes that the autoist holds in the highest esteem in a carbureter, for failure to start is probably the greatest of bugbears that afflict the driver, and

SECTIONAL VIEW WILLET CARBURETER.

frequently it is impossible to obtain anything better than gasoline of a grade that would not be considered for a moment under ordinary circumstances. Add to these the ability to develop plenty of power when throttled way down and to show up at its best when hill climbing, and a combination that is hard to beat is found. It is represented by the Willet carbureter, made by the Willet Engine and Carbureter Co., 764 Ellicott Sq., Buffalo, N. Y. The small number of parts used in its construction as well as the simplicity of the latter will be apparent at a glance at the accompanying sectional elevation of the carbureter. The gasoline inlet and float chamber are shown to the right with the air intake at the left. Instead of the usual single nozzle there are a series of six small tubes, as indicated at C, which form individual nozzles and are fed by the inlet at the bottom, which is regulated in the usual manner. After entering the air passes through a series of small circular openings at B; owing to the restricted area of the latter and the close proximity of the air stream to the jets, considerable gasoline is picked up even at slow speeds. An inverted cone-shaped valve D controls the auxiliary supply of air which is thrown into immediate contact with the vapor-laden air coming from the jets, this arrangement making the carbureter very sensitive. The mixture passes to the chamber E, in which is located a rotary throttle of the usual type. The Willet carbureter is said to have proved very successful in connection with the two-cycle engine.

Economy, Efficiency and Safety

¶The NATIONAL Gasoline Storage System is the most economical, because it entirely eliminates evaporation and waste of gasoline ¶It is the most efficient because the NATIONAL Pump discharges gasoline at every movement of the crank, and is always ready to operate ¶It is the safest, because it meets ALL of the requirements of The National Board of Fire Underwriters.

THE AUTOMOBILE

COCOTTE is dying. Perhaps you have never heard of Cocotte and have no tears to shed or any tender feelings of sympathy which swell up in your breast on the news of her approaching demise. Or maybe you are one of those who met Cocotte in the bone—for she never had much flesh—and wrote indignant letters to the *Paris Herald* denouncing her heavy-handed taskmaster and received as sole reply to your wrathful epistle an intimation from some fire-eating Parisian that if there were whipped cab horses in Paris there were also lynched negroes in America. In either case you are not likely to be moved by the momentous announcement, "Cocotte is dying."

The Dumb Tragedy of the Paris Cab Horse.

Cocotte is important numerically, for does she not represent at least 30,000 of the hippomobile population of the world's automobile capital? She came from nobody knows where; she showed a little spirit on the wilds of the fortifications as she dragged a frame on wheels and a couple of men along at a rapid clip. She bolted twice, perhaps thrice, when the sights of the gay capital were new to her and cab shafts were a novelty. But for five years she jogged along at a leisurely pace, indifferent whether her load were a consignment of market produce or an operatic star and her elegant admirer. Finally, worn out with wanderings, beatings and scant oats, she went—well, we had better not ask where she went. The question might revive memories of a windy city in the West.

The burly individual who had tickled her ribs through rain and sunshine was allotted another and younger animal, which was also christened Cocotte, and the cycle of operations recommenced. The lordly *cocher* came from wild Auvergne, generally. His utterance of *Fouchtre alors* would remove any doubt on that

point, even if his features and burly form allowed of the question. His costume was varied: a shiny white hat in summer; a shiny black one in winter. Carpet slippers in summer; wooden sabots in winter. A shirt, a coat, and pants in summer; the same, with the addition of innumerable coats, rugs, capes, and hoods in winter. A stout whip always.

The first signs of the coming revolution were visible three years ago, when an automobile gasoline cab made its appearance and, with the taximeter as a guarantee, offered to carry whoever cared to mount for the same minimum fare as the hippomobile. The distance was shorter, but that was a detail. A few months later 100 Renault cabs, two-cylinder engine, 8-10 horsepower, shaft drive, as the makers' description briefly

described them, were flitting all over the capital.

The real Parisian is not generally in a hurry and might not have deserted Cocotte and her mountaineer driver had there been no other inducement than a saving of time. To ride en auto was a big attraction, to ride en auto for about the same price as behind a horse was excellent; to ride en auto and see how much you owed as you traveled along and be able to dismiss your chauffeur when he became too costly, that was exquisite.

How a New Industry Sprang to Life.

The Renault Brothers were not allowed to long remain the sole furnishers of Paris auto cabs. In a few months, Panhard, Darracq, Bayard-Clément and a score of others were studying the details of a cheap vehicle which would run 365 days a year, could not be upset by a bungling driver and would never be seized with sudden and stupid immobility. Their efforts were successful, for, with mushroom growth, additions to the factories sprung up on a magnitude that indicated a desire to replace not only the Paris fleet of 10,000 horse cabs, but that of many a foreign city. At present there are five companies, the largest owning 1,000 cabs, the smallest 100, all in active operation in Paris. The passing of the horse, in this particular field, will

PLENTY OF TIME FOR REST.

The noted
Paris Cabby
is Losing
His Job

take about two years more, by which time there will be about 8,000 automobile cabs in the city and a handful of horse vehicles for timid maiden ladies who were once young.

Stroll along the Champs-Élysées, the Avenue du Bois, the main boulevards and other quarters where cab circulation is intense, and you will almost be persuaded that the mechanical has already surpassed the equine in numerical value. The horse cab has been driven to the railroad stations and the more distant stands, where waiting jobs mingle with paying ones. The auto cab sticks to fashionable main thoroughfares, and is rarely on the waiting list.

The Revolution of the 'Bus System.

Ever travel on a Paris horse 'bus? If you have not, and you are anxious to indulge in that leisurely recreation, you must not delay your visit to Europe, for the horse 'bus, like the cab, is passing and passing rapidly. Had not old Madame C. G. O. a monopoly on this class of transportation the change would have taken place a few years ago. But there was no necessity to move, and consequently no one did move until one day it was remembered that the old lady's lease of life would expire shortly. Then 40-horsepower automobile 'buses were ordered and placed in service from east to west, where they had to compete with the sub-

Ponderous
Autobuses
are Becoming
Numerous

way. Hilly Montmartre was next invaded, and the antiquated-looking individual who stood at the foot of the hill with the spare horse was put out of existence with one stroke. It was a sensation to the Parisian, used for long years to mount the steep grades at a snail's pace and occasionally get off to give a helping hand to the struggling beasts, to find themselves rushed up the slope at twelve miles an hour, with never a stop and never an encouraging shout or the crack of a whip.

In three years there will not be a horse-drawn 'bus in Paris. It requires no special wisdom to fix the date, for the present company's lease expires in 1910, and in June of that year 800 auto 'buses will replace the 700 horse vehicles, which, together with the hundred motor vehicles transport the traveling population of Paris. Darracq, the Napoleon of the motor world, is planning to control the 800 for a period of thirty-five years, and has already matured his plans for building, storing, and conducting his heavy brigade. The horse 'bus drivers have proved excellent chauffeurs. Some of them laid by the ribbons to take to the steering wheel with sore regret. You cannot drown the horse-love of a man in a day. But in a short time they were enthusiastic over their new charges and would not transfer to the old order, even if that were possible.

It is interesting to note that the first automobile 'buses to be used in Paris employ alcohol as a fuel. It does not appear, indeed, as if gasoline would have a chance to show its merits, for, if the Darracq-Serpollet Company obtains hold of the new lease, as is exceedingly probable, steam will be the successor. The present 'buses have four-cylinder engines, carried under the drivers' seat, ignition by high-tension magneto, and shaft drive through a special type of rear axle. The body is the one used on the horse vehicles with the addition of a permanent wood top. It is not likely that the company will convert its entire stock of vehicles, in view of the shortness of its life, but every month a certain number of horses are laid aside and mechanical power put in their place.

Passing from the Postal, Military and Municipal Service.

Electricity captivated the Paris postal authorities two or three years ago. The old way was to collect the mails from the numerous sub-offices by horse vans, which were generally sure, but never swift. The electric gave a quicker service and allowed the departure of mails to be fixed often two hours later than formerly. The horse is passing here, for a recent decree has gone forth that another big batch of horse-drawn vans must make way for the swift and silent electric.

Down on the riverside, just behind the police headquarters, where unfashionable Paris unites every morning bearing the goods found on land and water the previous night, is the horseless fire station. There is no shining harness, no well-groomed steeds, no newly laid straw and plaited mats. In their place are three automobile fire engines ready at the first turn of the crank to rush off to the accompaniment of a monotonous hoo-hoo-hoo which is the delight of the small boy and the joy of the idler.

Nobody knows Paris who has not wandered through its streets by night as well as by day. Have you ever got up at five o'clock, or stayed up until that hour, and meandered along the boulevards when they are in the possession of the man with the hose pipe, the newspaper delivery van and the scavenger teams? Under the old system the latter consists of a two-horse team, a couple of men, a loud-voiced youth with a whip, and a couple of women. It is difficult to understand why a woman should enlist in such an unsavory expedition. Perhaps the team is a family affair in which case the woman would be a necessity on the French principle that the woman must always be at the head of the family business. From 5 to 9 o'clock they make their round, seizing the garbage cans laid out for them, emptying the contents into their cart, the operation accompanied by much cracking of whip, shouting to the horse, to one another, and to any passerby who is talkatively inclined. When the horse falls, as often happens in winter, he is lashed until he gets up, or until his companion falls by his side, when with more shouting and cursing the two are

unharnessed and invited to rise to the accompaniment of more cracking of the whip and persuasive phrases. The new method consists of a huge automobile wagon which swiftly moves along, two men in the vehicle to receive the cans, two men on foot to throw them up. The work is carried on so quickly that there is no time for wayside conversation with belated cabbies or wearied policemen. Clatter, clatter, go the cans, as they are flung up and as quickly tossed down. Before the horse team has finished a block the motor wagon is half a mile down the street, and when a calculation of the amount of work done is made it is found that the auto scavenger has accomplished as much as five horse teams.

Street Cleaning Up to Date.

The horse is having to move out of the street cleaning department. Formerly a lean horse drew a revolving brush through the streets. The brush had to be kept at work during the day, when streets were crowded with quickly-moving traffic. The leisurely vehicle caused a block in the entire street, for the fastest vehicles, unable to pass round, had to accommodate their speed to his. This was especially the case in the fashionable Avenue du Bois de Boulogne, where the traffic consisted either of rapid automobiles or elegant driving teams. A machine had to be devised which could sweep and water the road without

For Street Cleaning the New Plan Excels

There's Much Time Saved in Post Collecting

garrison, near Paris, brought up thirty or forty automobiles of a very nondescript character to be passed in review by Captain Genty, better known to the automobile public as De la Touloubre, the Grand Prix race driver. Among the drivers of the machines was Edmond, of the Renault racing team.

Business houses, the large stores in particular, were the first to realize the benefit of the automobile, and there is not a store of importance that has not a large percentage of its delivery service performed by electric or gasoline vehicles. Among small firms the increase has lately been on a rapid scale.

Owing to the changed conditions, new street regulations have been applied to the traffic in the Champs-Elysées. Motor vehicles are confined to the center portion, horse vehicles have to keep to the sides, both in ascending and descending. An advantage for the automobile which had never previously attracted attention has been brought to light by this arrangement. The centre track, used exclusively by motor vehicles, is always clean; the two side tracks, used by horse vehicles, requires constant sweeping. Already the center track has become too crowded for the cars, and the Parisian is amusing himself by speculations as to how M. Lépine will regulate traffic when the horse has gone.

blocking the traffic. The outcome was the creation of a special type of automobile street sweeper and water wagon.

The horse-drawn surface car, like the horse 'bus, is but the child of a monopoly. He has not yet entirely passed off the stage of busy every-day life, but his passage is so far advanced that it may be considered as an accomplished fact. Electric surface cars, steam cars, and finally the rapid automobile 'bus, have made him appear as antiquated as the dodo. In a few of the quiet quarters, which the globe-trotter never visits in his busy haste, the horse-drawn species draws to a close its long easy-going career. Nobody protests against the slow service, for all know that the horse is passing, and the Parisian has a heart for the antique.

Gasoline has entered the army. This is probably its greatest victory, for the military authorities are always the most conservative and are never known to take to a new idea until it has been thoroughly tried by private enterprise. Now, instead of conveying sick soldiers from the barracks to the hospital by horses, they are transported in rapid Panhard automobiles with bodies specially constructed for this work. Every private vehicle owes a certain amount of service to the army, and as horse vehicles are being replaced by mechanically-driven conveyances, the number of automobiles presenting themselves for service with the troops grows larger every year. A recent inspection at the Vincennes

Removing the Refuse from the Streets

SOME REMEDIES FOR ROADSIDE TROUBLES

By THE MAN AT THE WHEEL.

"LET me tell you, not to overlook a spare valve when you're on tour," interjected one of the group of chauffeurs who up to that time had been a silent listener to the conversation regarding emergency repairs and the value of spare parts. "Of course, there's not one chance in a good many that it will be needed, but that's the one you carry it for, and it doesn't take up much room. Last summer, we were on a long trip and one fine afternoon when we were many miles from nowhere, one of the exhaust valve stems broke clean in two where it was drilled to retain the spring. The governor, he was riled at the idea of being hung up somewhere to wait for a new one. What he doesn't know about a car would fill a library, but he thinks I could build one with a hammer and a jackknife, so he says to me: 'Of course, you can fix that easy enough, Jack.' I wasn't so sure of it myself, but I took both valves out of that cylinder—the fourth—plugged the intake with a piece of waste, and we drove on three. The boss didn't seem to notice the difference and thought I had fixed things already; he was telling the women folks what a fine, clever lad I was. I wasn't saying anything, just thinking hard, for I knew we had some stiff work ahead and there'd be trouble with only three cylinders working.

"I thought and thought, and decided it was a new valve or nothing half a dozen times over, and every time the question would come back, 'Where are you going to get it?' We made a small town early and decided to put up there, which favored me. As soon as I could make it, I hiked to the blacksmith shop to see what could be done. 'Weld it,' says the man with the leather apron right off. But it didn't appeal to me at all; it meant three or four hours work drilling it and getting it back to the right length again with a file, and I knew the governor wanted to get away bright and early next day, so I said nay—a blacksmith's weld is not always a thing of beauty and I didn't feel just like spending half the night tinkering. He gave me up as a bad job and had no further suggestions, so I nosed around, still thinking hard. I found some odd pieces of stiff brass tubing lying around the bench and had an inspiration—some of it was just the size to slip over the valve stem with a good fit. The tinker had a good set of taps and dies and the rest was easy. I threaded the broken ends of the stem and tapped the tube, screwed the whole business together and drilled it for the spring end. It worked like a charm."

Stopping as a Symptom of Trouble.

"There are lots of rules and regulations handed out by the motor-wise on how to tell when there is something wrong with the engine; some of them are good, some bad, and more of them are hard for a new hand to remember," I overheard an experienced chauffeur telling some of his friends recently. "You can be dead certain that there's something wrong when she stops," he went on, "but there's a whole lot in noticing just how she died, and when you get wise to it, you'll wonder why you didn't think of it before. I make it a rule to always take it into account and it's a practice that has saved me lots of time on the road. If the engine shuts right off without any warning whatever, you can make up your mind right then and there that it's ignition trouble pure and simple—something has happened to cut off the 'juice.' Ninety-nine cases out of a hundred you'll find it's either a loose connection or a broken wire, and it's certainly wonderful how some connections will work loose no matter how carefully you tighten them up with the pliers.

"But when the engine begins to slow down and then pick up again and slow down some more, repeating that performance and running in starts and jerks, you have your choice of a weak battery or a partly plugged-up carbureter nozzle—of course, you have to take other things about the car into consideration in trying to make up your mind what the trouble happens to be; if

you know the accumulators haven't been recharged for a month or two past, there's little use of blaming the carbureter. But sometimes a dying battery will make the engine slow down gradually until she stops just about the same as the gasoline giving out will, though more often than not she'll turn up fine on what's left in the carbureter and then peter out within a minute or two as the last drop is used up. Fitful running, whether it ends up with a stop or not, usually means carbureter or fuel trouble somewhere along the line. There's a good deal to be learned about taking care of a motor that isn't in the books, and watching how she comes to a stop is one of them that you can only learn by experience."

To Prevent the Trembler Blade Sticking.

Correct adjustment of the coil tremblers is out of the question after the platinum points become pitted owing to the irregularity of the surfaces left by the action of the current. If badly eaten away, as is apt to be the case after long service, the only remedy is a complete renewal, but if the trouble be still in its earliest stages, trueing up will usually suffice. Starting with the points in good condition, it will be found that trouble from this source can be avoided to a very great extent by reversing the direction of the primary current at stated intervals, and autoists are coming to realize the benefit arising from this expedient more and more. This arises from the fact that the electrolytic action is always in the direction of current flow, the positive electrode or terminal being disintegrated by the passage of the current and a perceptible amount of the fused metal in a very finely divided state being deposited on the other terminal. Where the contact point on the trembler blade forms the positive terminal, finely divided platinum tends to deposit on the stationary or bridge point and vice versa, so that it will be evident that a reversal of the current flow will likewise reverse this action and to a large extent prevent the trouble that otherwise will arise from it sooner or later.

Carrying Accumulators on the Car.

While there is usually nothing fragile about an accumulator and its component parts are not over easily broken, it will be found a wise precaution to carry it on the car as if such were the case. It should not be rigidly fastened to any part of the car, but rather should be packed with some springy, yielding material that will absorb the greater part of the shocks due to jolting over the road, as well as the more or less constant vibration to which it is subjected. The reason for this does not arise from any motive of cleanliness, as the matter of spilling electrolyte is taken care of in the majority of cases by patented devices which permit the escape of the hydrogen, but prevent the acid from being shaken out through the vent. The greatest danger arises from the possibility of loosening the active material from the plates. True, this is forced into lockpockets under great pressure, but it must at the same time be porous in order to be efficient, and in trying to attain both extremes, the maker has to halt at some middle ground. It is safe to say that there is no accumulator made the plates of which will not suffer to a greater or less extent from being subjected to a constant pounding and shaking about. When sufficient of the active material has been loosened and fallen to the bottom of the cell to reach to the bottoms of the plates, the cell will be short-circuited and put out of action. It seems rather superfluous to add that in addition to the precaution of thus carrying the accumulator, no loose tools or pieces of metal should be permitted in the same case with it, but investigation of any number of cars sometimes reveals startling conditions in this as well as other respects. Some makers guarantee that their cells will not be injured by being placed on a dead short-circuit, but even accepting this at its face value, it will be found better to exclude screwdrivers and loose metal from the battery box.

BETWEEN New York and Boston there is some 250 miles of road which alternates from good to bad and bad to good with annoying frequency. Sometimes it becomes very bad; torn up by trolley-line builders or for the purposes of sewers and other street work. If there were a highway for automobiles—and one will be built in the not distant future—one could travel from Madison Square to the Common at speed equal to that of the "Mayflower Limited," and more healthfully and enjoyably, and at a schedule of your own choosing.

'Tis not so very long ago that the Automobile Club of America promoted an endurance run between the two towns and allowed three days for the journey each way. Searchlights which showed the road ahead in reassuring manner had yet to reach general use, and so there were night stops at New Haven and Springfield. That run supplied evidence that much harder tasks did not feaze the improving auto, which was rapidly making apparent its worth under conditions far from favorable.

There were four of us: Robbins, who drove; Van Cleve, whose long suit is publicity; Curry, who dips his pen in vitriol on occasion, and this editor, who blue-pencils more than he writes. Advocates of air-cooling have neglected the non-stop idea, and Robbins wanted to do a stunt of this sort with an Aerocar of this type, though it might be parenthetically injected that the same concern markets a water-cooled model. It follows naturally when one wants to avoid undue risk of stopping the engine that he drives with a greater caution than is the case when speed is the prime requisite.

A few straggling, late, home-going citizens curiously watched the flashlighting of the car and its quartette of occupants, taken at the corner of Broadway and Seventy-third street, and at 1:15 A.M. we turned northward, thoroughly awake and aware that a cheerless dawn was to be found somewhere in Connecticut. As we crossed the tracks of Amsterdam avenue at 110th street an inner tube gave up its life. It was a poor beginning. Again on our way, we were soon across Central bridge and rolling out Jerome avenue. Unannoyed by the overzealous "bike cop," we shortly struck the "Shore Road" and felt that the journey was actually begun.

Two black cats scurried across the road, and there was doubt expressed as to luck coming in the wake of such a pair. Humming musically, the motor dispelled any haunting fears, and we flew along, subdued by the raw night air, but inwardly confident of the ability of the pilot and his craft. New Rochelle, peacefully sleeping; Larchmont, sloping down to the Sound; aristocratic Mamaroneck and Rye—these fell to the rear. The milkman was

pursuing his early rounds as we sped through Port Chester, and policemen, wide-awake and watchful, were in plain sight.

A couple of miles more and we bade good-bye to the Empire State and entered the domain of the "Nutmeggers." Through Greenwich we caught a weird and ghostlike impression of the Soldiers' monument in front of the large stone church. Down "Put's Hill"—the one of the stone steps and scene of General Putnam's escape from the "Redcoats"—we went at a clip none too careful. Mianus, Stamford, Darien (where traps grow with suddenness in springtime), Norwalk, and Southport—all looked familiar in the coming of the cold, gray dawn. Someone tried a joke about something or other, but only the alleged humorist laughed after the telling. One doesn't indulge in plenteous laughter at break-o'-day traveling the open road on a sunless morn of a backward spring. I must ask Van Cleve to try his funny story under more propitious circumstances.

But the truth must be told. Robbins was having some trouble with the engine. It was baffling; the throttle acted contrary—advanced, it refused to give additional compression pressure and obstinately stuck. After the non-plussed operator had allowed his motor to come to a painful halt, and all of us had indulged in a few choice expletives, it was discovered that a measley little set screw holding the lever had become loose.

Before was Bridgeport; we had covered fifty-eight miles, and it was 5 o'clock. Yes, we would breakfast at New Haven, and then hold a council of war with full stomachs. Humanity was getting up now, and the road that led to Yale Common gained in activity as we neared the town of the classic elms. Though the New Haven House couldn't supply the finnan haddie for which Robbins craved, the breakfast left us in a more optimistic mood. The vote to continue and try for a one-stop score was unanimous. We had come eighty miles; Hartford was straight ahead forty-two miles; Boston lay some 124 miles beyond Connecticut's capital. Over an hour had been taken for the leisurely eating of the first meal of the day, and the hands of the clock pointed at 8:10 as we turned out Temple street.

Wallingford streets were filled with loitering schoolboys, reluctantly responding to the call of the imperative bell that meant an innings of instruction. Meriden was energetically at work as Robbins carefully steered through its busy thoroughfares, considerate of other users of the road, and making speed only when traffic conditions

made it safely possible. If all drove the way Robbins did during that long day there would be slight and then unfair antagonism from those who divide the road with the autoists. Frightened horses during the entire trip could be counted upon a single hand, and none of these were much more than merely excited.

CROSSING THE CONNECTICUT.

ONLY A STOP FOR A NEW ENGLAND SNAPSHOT.

Old Sol poked through the clouds as we entered New Britain, the home of the air-cooled Corbin. A practical sight met our eyes and reminded us that the thrifty New England housewife was at her spring cleaning. The engine of a Ford runabout, located in front of a spacious mansion, was supplying the power for a vacuum cleaner.

Hartford looked picturesque as we neared, the Glastenbury Range contributing to the inviting scene. Following the trolleys into Farmington avenue, we passed the house in the building of which Mark Twain placed the kitchen so that it looks out upon the avenue. His explanation was that it would save time for his servants in giving them constant opportunity of seeing all that was going on. Then it would be unnecessary for them to go through the entire house and peek through the blinds.

Emerging from Hartford, we were soon in sight of the placid and broad Connecticut, majestically winding its way to the sea. At Windsor Locks we crossed the river, and that which one sees from here to Springfield is typically colonial and restful, far from the madding throng. A stretch of sandy road gives your motor something to do, but ours was on its good behavior, and it never uttered a protest, as if anxious to make amends for the stop before Bridgeport, for which it was not to blame.

It is certainly beautiful country between Springfield and Worcester. Palmer was our lunching place, and we wasted the greater part of an hour. Sure enough, going through Leicester, there stood the famous auto deputies, watches in hand, and spectators on both sides of the street grinning unmistakably to see if we were to be victims of the limbs of the law. No, we were "wise," and crawled through the trap at a funeral pace. "Jim" Quinn was not on duty, and so we slid down into Worcester without a sight of that worthy.

Roads of the real kind carried us along at a pleasing clip. 'Twas 3:30 as we scurried through Marlboro, and once more we saw the schoolboy, and this time he was gleefully escaping from the house of learning. There was no call for us at the "Wayside Inn" in South Sudbury, but Curry reminded us that it was the old hostelry made famous by Hawthorne in his "Tales of a Wayside Inn." The A. C. A. signs were mighty helpful in going through Waltham and finally reaching the beginning of Boston's great park system, superior to anything possessed by any other city. Exactly 5 o'clock on the hour was the time of our arrival in front of "Pop" Lowe's in Tremont street, and, of course, he and a contingent of newspapermen were there to say "Hello!" Our net time for the run was about twelve hours, and in refreshment for men and machine and the tire and single stop incident three hours thirty minutes had been consumed. Nothing startling! No, nothing startling, except to demonstrate how the Boston-New York trip can be done without undue exertion in much less than a day where once the daylight of three days were thought necessary. And over that autoway of the near future the jaunt will be one of less than five hours.

* * * *

It bore the appearance of rain on Wednesday morning, and Curry and I took train back to New York. Not so with Robbins and Van Cleve. They wanted to have another, and the pilot hungered to do the job without a stop of the engine. Starting Thursday at 9 A.M., and blessed with daylight until Larchmont was reached, the air-cooler reported at Broadway and Seventy-third street at 8:23 P.M. This meant a total time of 11 hours 23 minutes, and the net figures were 9 hours 23 minutes. It ought to be mentioned that this Model D was the same one which ploughed over the snow and mud-soaked roads between the two cities in March last at the time of the Boston Show.

The use of special steels for rivets was the subject of a communication to the Paris Academy of Sciences lately by M. G. Charpy. A systematic study of the thermal and mechanical properties of various alloys of steel has led to the use of a chrome nickel steel for rivets, the strength of which is 2.5 times that of the metal usually employed for this purpose, and this without the need of any special precautions in practical use.

THE AUTOMOBILE CALENDAR. AMERICAN.

Shows and Meetings.

- May 28-31.....—Indianapolis, Ind., Annual Meeting American Society of Mechanical Engineers.
Oct. 31-Nov. 7.....—New York City, Madison Square Garden, Eighth Annual Automobile Show, Association of Licensed Automobile Manufacturers.
Nov. 30-Dec. 7.....—Chicago, Coliseum and First Regt. Army, Eighth Annual National Automobile Show, National Association of Automobile Manufacturers.

Races, Hill-Climbs, etc.

- May 6-7.....—Harrisburg, Pa., Two-day Endurance Run, Motor Club of Harrisburg.
May 30.....—Philadelphia, Hill Climb, Monk's Hill, Quaker City Motor Club.
May 30.....—Chicago, Memorial Day Race Meet of the Chicago Motor Club.
May 30.....—Bridgeport, Conn., Hill Climb, Bridgeport Automobile Club.
May 30-June 1.....—Newark, N. J., Three-day Endurance Run of the New Jersey Automobile and Motor Club.
June 12.....—National Orphans' Day, instituted by the American Automobile Association.
June 19-22.....—New York City, Sealed Bonnet Contest, under the auspices of the Automobile Club of America.
June 20.....—Albany, N. Y., Annual Tour of the Albany Automobile Club; Route, via New York and Asbury Park, to Atlantic City.
July 10.....—Cleveland, O., Start of Fourth Annual Tour of the American Automobile Association, for the Glidden Trophy. Finishes in New York City on or about July 23.
Sept. 14.....—Albany, N. Y., Road Race under the auspices of the Albany Automobile Club.
Oct. 19.....—St. Louis, Mo., International Aerial Race of the Gordon Bennett Prize. Aero Club of America.

FOREIGN.

Shows.

- May 4-15.....—Madrid, Spain, Automobile Exhibition, Palace of Fine Arts, Royal Automobile Club of Madrid.
May 15-26.....—Zurich, Third Annual Swiss Automobile Show.
June 25-30.....—St. Petersburg, Russia, Automobile Show.
Nov. 12-Dec. 1.....—Paris, Exposition Decennale de l'Automobile, Grand Palais, Esplanade des Invalides, Automobile Club of France.

Races, Hill-Climbs, etc.

- May 15-31.....—Belgium, Industrial Vehicle Trials, Automobile Club du Nord.
May 18-21.....—Milan, Italy, Touring Club Trials.
May 22-25.....—Irish Automobile Club Reliability Trials.
May 24-27.....—Voiturette Contest, Automobile Club of Austria.
May 28.....—Isle of Man, Tourist Trophy Race, Automobile Club of Great Britain and Ireland.
May 30.....—Isle of Man, Heavy Touring Car Race, Automobile Club of Great Britain and Ireland.
June 3-12.....—Paris, Electric Vehicle Competition, Automobile Club of France.
June 3-12.....—Herkomer Cup, Automobile Club of Bavaria.
June 14.....—German Emperor's Cup, Taunus Circuit, Imperial Automobile Club.
June 20-22.....—American Gold Cup, Start from New York of European Tour for American Cars, Georges Dupuy, secretary, 1402 Broadway, New York City.
June 14-29.....—Scottish Reliability Trial, Scottish Automobile Club.
July 2.....—Grand Prix, Automobile Club of France.
July 14, 1908.....—Paris to London, Aerial Race.
July 15-18.....—Ostend Week, Record Trials, Automobile Club of Belgium.
July 21.....—Ardennes Circuit (Belgium).
July 31.....—Liederkerke Cup for Touring Cars, Ardennes Circuit, Belgium.
July 31-Aug. 8.....—Belgium Regularity Contest for Touring Cars, A. C. of Belgium.
August 1-7.....—Criterium of France, 1,750 Miles Touring Competition and 250-mile Race for the Press Cup, A. C. of France.
August 11-29.....—France, Coupe de Auvergne.
Sept. 1.....—Italy, Brescia Circuit, Florio Cup, A. C. of Italy.

FROM BOTH SIDES OF THE SELDEN PATENT FENCE

FROM A. L. A. M. PUBLICITY BUREAU

SELDEN ACTION AGAINST INFRINGERS.

The spirit of activity that has been noticeable at the offices of the Association of Licensed Automobile Manufacturers for the past few weeks, developed Friday in a manner that proves that the owners of the Selden patent are determined to bring the validity of this famous patent to an early decision. Suits were instituted against nine infringing manufacturers or their representatives who are located in New York. The action of the owners of the Selden patent in bringing these new suits caused considerable uneasiness on the part of the dealers or representatives of the infringing manufacturers, as in some cases they did not know to what extent the manufacturers would protect them in this matter.

It had been understood for some time that the so-called test case against the Ford Motor Company, as manufacturer; John Wanamaker, as dealer, and O. J. Gude, as user, would be the only suit against the manufacturers of automobiles, not licensed under the Selden patent, so that these new actions caused no little surprise and consternation among the local automobile fraternity. Papers were served on the dealers or manufacturers of the following unlicensed cars: Maxwell, Mitchell, Aerocar, Rambler, Rainier, Premier, Marmon, Stoddard-Dayton and National.

Why so many suits should be brought at this time was the cause of much speculation, but it has been learned there were various causes; among others, it appears that the bringing of the large number of suits before the decision of the so-called test cases is frequently resorted to in order that such suits may be in condition for prompt action immediately upon the entering of the main decree sustaining the patent.

At the same time, it would seem as if the principal cause was the attempt of some infringers to leave the Federal jurisdiction in which the main suits under the Selden patent were being prosecuted. In this connection, for several months past it has been known that an unlicensed manufacturer near New York City had purchased a factory site in the West, and would, as soon as possible, remove his entire plant. While this action was publicly attributed to his finding better factory facilities in the West, and also better labor conditions, as well as several other excuses, it is understood now that those in his confidence learned from the manufacturer in question that the main object was to leave the jurisdiction of the Federal Circuit Court in which he believed there would be, at an early date, a favorable decision under the Selden patent.

It appears also that in the last few months there has been a considerable reduction in the number of direct representatives of unlicensed automobiles, and that on the other hand the unlicensed cars still being handled in New York have been sold by individuals or companies organized solely for selling, with no legal connection with the factory as exists in other cases where branch houses are established.

The bringing of many suits under the Selden patent, it is said, will enable the owners of those rights to take summary action immediately after the filing of the decision sustaining the patent in the so-called test case. On the other hand, it is also stated that unlicensed dealers have been persuading the buying public that they need not respect the Selden patent, and, in fact, it is frankly stated that there appears to be so much ignorance on the part of infringers whether manufacturers, or users, that the only safe course was found to be in the serving of papers to impress upon the unlicensed dealers and manufacturers the proper realization of their unlawful business. It is calculated the bringing of these suits, among other things, will stop misinformed

(Continued on first column, page 736.)

FROM FORD MOTOR CO. PRESS BUREAU.

WHAT HENRY FORD HAS TO SAY IN REPLY.

Henry Ford, president of the Ford Motor Company, which has been fighting the alleged Selden patent for the past four years, was interviewed over the long-distance 'phone Saturday on the move. He was at the factory in Detroit. Among other things, Mr. Ford said:

"The press notice that the Association of Licensed Automobile Manufacturers has undertaken to sue some more manufacturers, is a fitting climax to some of their other childlike acts during the past few months. Driven to desperation by the unexpected developments and the exposure of their weak structure, nothing else was to be expected but a move of this kind. When nothing substantial can be shown, the officers of the A. L. A. M. seem ever ready to start suits against some small dealer. It is a pitiable state of affairs and shows that the predictions of the Licensed Association going to smash within the next few months seems likely to prove true.

"The ingeniously built structure that proposed to have a monopoly of motor car manufacture and boost prices accordingly, is nearing its end. The promised monopoly has failed to materialize, some eighty good manufacturers declining to pay royalty, while only thirty-two continue to give up money, although I understand many of these have stopped payments recently. Trust methods have failed to produce results, as the Association was too weak.

"Many things have occurred recently to make this latest move an expected one. Instead of continuing to fight with the Ford Company on which they started, they now try to annoy some New York dealers who happen to handle cars not made by their members. I notice that they didn't talk of serving the big manufacturers themselves. Even in New York, they don't go near the American Locomotive Company, for they look too big.

"I take it that the Licensed Association did not relish the exposure at the trial of the Searchmont Company against them which showed the tremendous sums paid in royalties, of which almost half, amounting to \$228,342, went to the lawyers. It was a soft pension fund for gentlemen like Messrs. Cuntz, Reading, Betts, and other attorneys and friends of the Electric Vehicle Company, which gets three-fifths of the royalties free and clear, and of which George H. Day, the former manager of the Association and the man who conceived it, was president. I understand, however, that Mr. Day has not been interested in the Electric Vehicle Company since the Licensed Association was formed.

"Other matters that have hurt the Licensed Association recently, was the exposure of the salaries and other expenses, amounting to \$223,902; the \$25 a day given to everyone who attends the frequent meetings held of the dozen committees; the fact that the much vaunted laboratory consists of a corner of Mr. Souther's laboratory in Hartford, for which a thousand dollars a year is paid, as Mr. Cutler testified. The movement of the twenty-five or more independent importers to organize against the seven or eight in the licensed association, didn't create the best of feeling among the latter, especially when it was known that they were trying to supply the importers with a date for their show during the holidays, which it is well known is the poorest time of the year. The officers undoubtedly feel that their own importers would quit and that the constant turmoil in which their present members move, would bring an outburst.

"I don't suppose the members who have been giving up good money like to be tricked by Mr. Selden himself, who bought the Buffalo Gasolene Motor Company in order to secure a license when one was refused him. Then the refusal of some of the

(Continued on second column, page 736.)

(Continued from first column, page 735)

automobile buyers from believing themselves safe in buying unlicensed gasoline automobiles. It is pointed out that there is a penalty for infringement of the Selden patent as well as every other patent, not alone by the manufacturers of an infringing article, but likewise for the sale of the article and the use, as in the case of owning and operating an automobile. While the hardest fought suits are now generally understood to be pending against manufacturers, the suits just brought are directed against a large number of agents or dealers and it is understood that the other thirty suits have been brought against individuals owning unlicensed cars. This would seem to indicate the general program to stamp out, root and branch, the manufacture and traffic of unlicensed cars infringing the exclusive rights granted by the United States Government when the pioneer Selden patent was issued.

FROM A. L. A. M. PUBLICITY BUREAU, APRIL 29.

SELDENITES BRING SIX MORE SUITS.

Following up the nine suits against the manufacture or sale of unlicensed cars comes the report that actions against six other unlicensed concerns were begun. Suits were filed and papers served against dealers in, and the manufacture of the following unlicensed cars: American Mors, DeLuxe, Wayne, Glide, Dragon and Welch.

The activity of the owners of the basic patent which covers broadly the manufacture, sale or use of gasoline automobiles, has come to many as a great surprise, especially to dealers or representatives of the manufacturers of the nine unlicensed cars which were sued yesterday. To some of these it did not appear that any importance was attached to the proceedings, as their manufacturers would undoubtedly assume the responsibility, the dealers not realizing the liability they were assuming, and the penalty attached to the handling of an article that was an infringement. In this connection, from the decisions of the United States Court, in similar actions, it is manifest that the rights granted a patentee must be respected, and the overstepping of these rights are attended not only in awarding damages to the owners of the patent, but also all profits made in the traffic in an unlicensed car.

Referring to the Much Discussed De Feher Case.

The case in the Selden patent, known as the De Feher case, at the time of the granting of the decree and injunction attracted considerable attention. An attempt, however, was made to depreciate its significance, owing to the defendant's lack of contention, but Judge Holland's decree made it clear that the defendant had infringed, and awarded the owners of the Selden patent, not alone damages, but costs and profits, with interest on same, and a perpetual injunction restraining the defendant from the further traffic in the unlicensed product.

The prosecution of the suits that have just been brought will be pushed as speedily as consistent with the thorough preparation of the cases.

It has been pointed out that the cars whose representatives have been sued, with one exception, have been in existence only during the past few years, and that they did not market any product until after the formation of the Association of Licensed Automobile Manufacturers in 1903. A person associated with some of the automobile manufacturers for more than twelve years has even gone so far as to say that, with one or possibly two exceptions, the companies that have been sued came into the field when standards of construction had already been established by practically all of the manufacturers now comprising the Association of Licensed Automobile Manufacturers.

Any impression that the owners of the Selden patent would not endeavor to prosecute all infringers independent of the test case against the Ford Motor Company will be dispelled by the activity which is being shown.

(Continued from second column, page 735)

importers to pay royalties, the status of the Thomas '40' factory and the new factory for Buick runabouts, were among other things that are making the Association the laughing stock of the automobile and business world.

"Led on to an early show by the action of the Automobile Club of America and the American Motor Car Manufacturers' Association, they have got their date too early. The internal trouble undoubtedly resulted in the resignation of Mr. Day, a gentleman for whom personally I have the greatest respect.

"It is worth noting, too, that the independent organization, the American Motor Car Manufacturers' Association, of which we are proud to be a member, has doubled its strength during the last year, now numbering forty-two American concerns, or ten more than the licensed folks, and moreover, these makers are doing the greatest business, for they sell their goods at proper prices; are not induced to boost it to an abnormal figure in order to pay royalty, and consequently are patronized by the public. The so-called licensed folks have only secured two new members in a year, notwithstanding some extraordinary soliciting. So far as the alleged Selden patent is concerned, even their own members look upon it as a joke. Issued fifteen years after the original application was filed, it has never been considered seriously except as a foundation to keep the field of motor car manufacture in the hands of a limited few.

"Once upon a time a few people considered it as a serious thing, but of late it has been a huge joke among automobilists generally.

"It is a pity that even so desperate a combination as the licensed association should stoop to methods of this sort, but I presume it is a case of life or death. They will doubtless hold off a decision as long as possible, for on a decision they have everything to lose and nothing to gain.

"Some of the reasons given in the press notices sent out by the licensed association for this action against a number of manufacturers, are humorous in the extreme."

ATTORNEY PARKER ON THE SITUATION.

When seen yesterday, R. A. Parker, counsel for the Ford Motor Company and for the Panhard Company, said with reference to the statement in question:

"The statement to which my attention is called, I assert is beyond doubt one issued to the newspapers directly from the officers of the Licensed Association, so-called, in which they seek to stamp and characterize their own actions and state their own motives as though such actions and motives had been described and characterized by an impartial observer.

"The motive for putting this matter of bringing further suits before the public in the manner in question is very clear. It is done simply as one of the last desperate moves in the great game of bluff that the officials of the Licensed Association have been playing for the last four years. We remind them of Lincoln's famous saying, 'You can fool some of the people all of the time; you may fool all of the people some of the time, but you can't fool all of the people all of the time.'

"The public may be sure there is a crisis pending in that association, or these new actions would not be brought, and especially that they would not be heralded under such false colors.

"To a person having inside information, it would be quite a natural supposition that the suits were brought for the express purpose of using up in attorney fees, etc., the surplus of some \$160,000 or so which the Searchmont suit disclosed was still on hand in the treasury of the association after the payment of upward of \$225,000 in legal expenses. As the Searchmont case was brought to secure a division of this surplus or of any surplus, it would be natural for some parties connected with the association to divert it in other directions and leave nothing to divide."

ALCOHOL AS A FUEL FOR THE AUTOMOBILE MOTOR*

By THOMAS L. WHITE.

IN considering the possibilities of alcohol as a fuel for automobile motors, it is impossible to avoid alluding, however briefly, to the economic conditions which must eventually determine its use as a fuel at all, and this independently of all technical considerations. Gasoline is the by-product of a geographically limited and monopolistically controlled industry, and there are reasons to believe that the available supply is more than mortgaged by a world-wide and growing demand.

Alcohol is, one might say, the product of the four seasons. It can be manufactured from any vegetable substance which contains sugar or some material like starch, which is easily convertible into sugar. As to available supply, it can be and will be produced in unlimited quantities at a steadily diminishing cost. From corn-cobs it has already been experimentally prepared at five cents a gallon, and there seems little reason to doubt that if the technical problems connected with its use can only be solved, and if, also, what is important at the present moment, its use can be reduced to current practice; if, in other words, some means can be devised of economically burning this fuel in the thousands of automobile motors in existence to-day, there is little doubt that the demand so created will be satisfactorily met, both as to quality, quantity and price.

Passing now to the question of denaturing, it is gratifying to see that Mr. Yerkes has yielded to the pressure brought to bear on him, and has reduced the quantity of added methylene from ten to two per cent. This, however, is only a step in the right direction. When the use of alcohol in motors becomes more general, I think that the motor industry will be entitled to demand the same special consideration in the matter of a suitable denaturant as is now accorded to the chloroform, vinegar, ether, and other industries where the selection of a denaturant suitable to the needs of the case is permitted. So far as the motor industry is concerned something like this is already in force in Germany and Austria, where motor alcohol is distinguished from domestic alcohol, that is, alcohol for general purposes of heat, light, and fuel. If I might make a suggestion, I think that the revenue would be sufficiently safeguarded if alcohol destined for use in motors was saturated with acetylene gas with possibly the addition of a little acetone to facilitate its solution.

Methylene as a denaturant has the one commanding advantage in the eyes of the revenue officials, that by no means known to science can it be separated from ethyl alcohol. In the motor, however, it is a disadvantage in every way. Its action is corrosive, its calorific value is low and it is costly. The less of it the better. If alcohol must be nasty, let it, at any rate, be cheap.

To come now to the main subject of this paper, namely, the use of alcohol in existing motors working with a compression of four to one, or thereabouts, whose r.p.m. rate is high; before going further it is as well to briefly review, even at the risk of being considered trite, the essential facts with which we have to deal. They are:

(1) Alcohol calls for six per cent. of its calorific value to completely evaporate it.

(2) With ordinary compression the inflammation rate of the motor alcohol is sluggish compared to gasoline.

(3) Alcohol containing ten per cent. of water is capable of very high compression (150 pounds upwards) without pre-ignition.

(4) Alcohol in the process of inflammation does not radiate heat so rapidly as gasoline.

(5) Expectation to the contrary, alcohol is most efficient as a fuel when the wall of the cylinder is maintained at a temperature of about 200° Fahr.

(6) When alcohol is used as a fuel the penalty of incomplete combustion is not merely loss of efficiency in the motor, but the

corrosion and destruction of valve seats and other exposed parts due to the production of acetic acid, formaldehyde, and other deleterious compounds.

It is a well-known fact that the efficiency of an Otto cycle is a function of the compression ratio. It follows that in motors specially constructed for alcohol we should expect a very high thermal efficiency, and this expectation is borne out in practice. With the Deutz motor using a nine to one compression a thermal efficiency of over thirty-one per cent. has been obtained, which shares with the Diesel the distinction of being the high-water mark of efficiency for explosion engines. In the case of the automobile motor, however, the problem is to accept the compression ratio as a datum and to seek efficiency in other directions. This essentially means that the use of alcohol under such conditions is a carburetion problem.

Speaking generally of alcohol motors, carburetion practice falls naturally into two divisions.

(1) Motors, like the Deutz, which have a high compression and in which the alcohol is simply sprayed into the ingoing air just as it enters the cylinder, the hot cylinder walls and the heat generated by compression being relied on to complete the evaporation.

(2) Motors, like the Dürr, in which the compression ratio is moderate, say six to one, and in which a superheated mixture of air and alcohol vapor is produced by exhaust-heated baffles situated in the carbureter itself.

In both cases the motor cannot be started by hand. In the first case, because the hand compression is not rapid enough to evaporate the atomized charge in the cylinder; in the second case, because there is a precipitation of the volatilized alcohol on the cold cylinder walls.

In efficiency tests these two types come out about level. Thus in the Dürr motor the perfect carburetion offsets the lower weight of the mixture and the lower compression ratio, while in the Deutz motor the thermal gain due to greater compression is qualified by the fact that the evaporation in the cylinder is never complete and consequently part of the fuel is wasted thermally by being burnt late in the stroke or not at all.

It is clear that in automobile practice we must seek something in the line of complete carburetion, even at the expense of reduced charge weight, so that in order to produce efficiency under existing conditions of motor construction we must aim at:—

(1) Perfect carburetion with the aid of the exhaust heat.

(2) The acceleration of the rate of inflammation in the cylinder.

(3) The maintenance of the cylinder walls at a temperature of about 200° Fahr.

Coming now to the actual phenomenon of combustion in the cylinder itself, it would seem that the slow inflammation rate of a mixture of alcohol vapor and air is a necessary corollary of the fact that such a mixture is susceptible of a high degree of compression without spontaneous ignition. It is, I think, now a recognized fact that when an inflammable mixture is ignited by a spark the propagation of the explosion is not due to direct consecutive ignition throughout the body of the gaseous mass, but to the successive compression to the self-ignition point of layers of gas immediately enclosing the inflamed nucleus at the moment considered. Now, if gasoline and air be ignited, the shell of gas surrounding the explosion focus has only to be compressed about five to one to spontaneously ignite throughout its extent. In the case of alcohol a much higher compression is necessary, so that the explosion acceleration is necessarily slower.

All commercial denatured alcohol contains ten per cent. of water, and the function of this water in the alcohol motor is practically an undetermined problem. There is reason to believe that the corrosive action so much complained of in alcohol motors is partly due to its presence, and it undoubtedly has something

* Paper read before the Society of Automobile Engineers.

to do with the high compression ratio. Of course, it is known that the presence of water in an inflammable mixture in a motor is not altogether a disadvantage. In the first place, combustion in the absolute absence of water is impossible. Thus phosphorus absolutely refuses to burn in pure oxygen. Then, again, we have the experiments of Banki and others, who have deliberately injected water into the cylinder during the compression stroke with a resulting increase of efficiency in the motor. I have not seen records of any experiments made with absolutely pure alcohol, but they would be decidedly interesting, if only as a guide. It is, however, generally believed that alcohol containing water is the better fuel.

In an address delivered last year, which is given *in extenso* in the *Scientific American*, Dugald Clerk showed that the development of the stationary motor shows a decrease of the heat loss into the water jacket and an increase of the heat loss into the exhaust. Indeed, what has been gained by the swings seems to have been lost on the roundabouts. Owing to its low radiative quality alcohol comes naturally into line with this tendency in modern practice. In fact, were it not for the necessity of maintaining a high cylinder wall temperature, the question of cooling an alcohol motor would be a simpler one than in the case of gasoline, as the actual amount of heat to be dealt with is less.

With regard to the chemical reactions which take place in an alcohol motor, there seems to be much doubt and much difference of opinion. As between French and German authorities there exists a sort of scientific Franco-German war. Thus, while on one hand we find Sorel, the French expert, attaching the greatest importance to the erosive effort of acetic acid formed by incomplete combustion, we have Fehrmann, the German expert, denying the existence of acetic acid altogether. Be this as it may, it seems to be a definitely ascertained fact that when the carburetion is incomplete, pitting of the inlet valve seat and the formation of an incrustation upon it result. As to what excess of air should be present seems largely to depend on the r.p.m. rate, and in this connection it should be remembered that the record efficiencies for the use of alcohol for motors have all been attained with a low r.p.m. rate, in some cases as low as 200.

One of the most mysterious phenomena of the explosion motor is heat suppression, or the addition of heat during the expansion stroke, so that the expansion curve remains above the adiabatic drawn between the same limits in spite of the fact that heat has been radiated all the time. This suppressed heat in the case of alcohol is, according to Sorel, greater than with a gas engine. So far as a comparison with gasoline is concerned, the advantage, judging from P. V. diagrams, appears to be slightly with alcohol.

It is now with some diffidence that I come to mention an attempted solution of the carburetion question due to Mr. Barker and myself. The two objects of our device are to carburete air with alcohol instantly and completely and to promote approximately instant inflammation at minimum compression in the motor. What we propose to do is to pass air containing partly atomized and partly vaporized alcohol through a layer of calcium carbide before such air enters the cylinder. A portion of the ten per cent. of water in the alcohol is taken up by the carbide and replaced by acetylene gas, and the heat of this reaction simultaneously vaporizes the alcohol. From the nature of its formation such a mixture of acetylene, alcohol vapor and air must necessarily be a very intimate one. In the cylinder we consequently have:—

(1) A well-diffused mixture.

(2) An endothermic compound in the form of acetylene, which contains heat over and above its thermal value and which spontaneously ignites at comparatively low pressures, so that when the mixture is fired the pressure set up round the spark plug causes the practically simultaneous detonation of the acetylene throughout the body of the alcohol.

Taking into consideration that the substitution of acetylene for water is a net gain calorifically, and that the elimination of this water will probably do away with much of the erosion complained of in alcohol motors, we hope to produce for the ordinary

automobile motor an alcohol-air-acetylene charge, whose characteristics thermally are not very different from those of a mixture of gasoline and air.

I had hoped to have had this apparatus running this week and to have been able to give actual figures of a trial run. There has, however, been some little delay in getting castings made, and although all the parts are now ready to be assembled and attached to De Dion motor coupled direct to a dynamo, we have not been able to get into running shape in time.

There is an impression in some quarters that alcohol has to some extent received a black eye in Europe. It would probably be more correct to say that, while with slow-going motors it has proved a great success, the development and perfection of the automobile motor have left little leisure to designers to study the alcohol problem with any thoroughness. In fact, it is more or less virgin forest, which the automobile engineer has to clear when he is dealing with the question of alcohol motors, and there is no reason whatever why America should not, with the resources which has been shown in other branches of engineering, lead the way. And if this happens, as I hope it will, the credit will be all the greater, for while in Europe gasoline is a heavily taxed import, in America it is an indigenous product.

ALCOHOL ENGINES IN SOUTH AFRICA.

According to the American Consul-General at Rio de Janeiro, the development of alcohol engines to take the place of engines in the United States as a result of the recent legislation for the use of denatured alcohol is watched with much interest in Brazil, says *Commercial Intelligence*. The manufacture of practical, simple and cheap alcohol motors similar to the motors now sold will, he thinks, meet a ready demand in Brazil. Gasoline is costly, and the difficulty of transporting it, passing it through the Customs, and caring for it afterwards, under very stringent regulations, has retarded the introduction of gasoline power in many lines. On the other hand, alcohol is cheap in Brazil, and most sugar-growing countries. Large quantities of it are exported, and immensely increased quantities could be made easily and cheaply, the present output being measured more by the demand for it than by the possibilities of production. The sugar alcohol in Brazil is used without any denaturing process. It comes in several grades, some of which are of too low degree to burn readily, but a demand for high-grade alcohol for power fuel or any similar purpose could and would be met quickly. Alcohol of export-grade has been shipped from Brazil in recent years at about 40 cents per gallon. The further development of the sugar industry, which is following increased demand for Brazilian sugar in Europe, will doubtless lead to the production of alcohol at a much lower cost. At present in Brazil it has few industrial uses.

HOW TO MAKE POLE-FINDING PAPER.

Pole-testing paper is a prepared paper which may be used for the finding of the negative and positive poles of an accumulator, says *Work*. One method of preparing it is as follows: Dissolve a teaspoonful of sodium sulphate in one-half pint of water, in which also dissolve about the same quantity of potassium iodide and of starch. To dissolve the starch the water must be heated. Soak white blotting paper in this solution, dry it, and cut into strips of any convenient size; 1-2 inch by 2 inches is suitable. Keep the paper in a dry place, such as a tin box or a glass bottle. To use, moisten a strip and place the two poles on it, near together or farther apart, according to the voltage of the current. A dark spot will appear at the positive pole. Another method is to dissolve 15 grains of phenol-phthalein in 1-2 ounce of common alcohol. Dissolve also 20 grains of sodium sulphate in four ounces of water. Soak blotting paper in the first solution and drain off the superfluous liquid. Then soak it in the second solution and dry it. Cut to size and use as before. A red spot appears at the negative pole.

BRAKES AND THEIR CARE AND REPAIR

By VICTOR LOUGHEED.

THERE is no part of an automobile ordinarily more neglected than the brakes. Despite their importance as a chief means of safeguarding the lives of the owner and his friends, for some reason there is a pronounced disregard of the elementary precautions necessary to insure their operative condition at all times. Cars otherwise excellently maintained often are seen with brakes in bad condition.

The reason for this slipshod attitude of so many drivers is not far to seek. Brakes are designed for two uses—one frequent but not exacting, the other of vital importance but of infrequent neces-

sity. This condition seems to inspire the average man with an inclination to gamble against the likelihood of his ever needing the brakes seriously, rather than with a disposition to depend upon their proper functioning.

The purpose of this article is to impress upon the reader the very great necessity for maintaining brakes in proper condition, while at the same time pointing out the principal essentials of such maintenance and condition. To this end it will be convenient first briefly to enumerate the more important types of brakes in common use, so that their normal condition may be at hand as an illustration of the points involved in maintenance, repair, and remodeling.

Kinds of Brakes.

Constricting Brakes, or band brakes, are of the general type shown in Fig. 1, in which *i* is the brake drum, attached to one of the wheels, and *m* is band capable of being powerfully constricted around *i* by a pull upon the lever *h*, through means of the rod *d*. The band *m* is lined with some material which sets up a powerful friction when forced into contact with *i*. In Fig. 2 a constricting brake of slightly different type is used, the characteristic feature being the two shoes *m m*, in place of the band *m* in Fig. 1. These shoes are drawn together by the action of the toggle joint *n* when a pull on the rod *d* moves *h* in the direction of the arrow. Another type of constricting brake is that sketched in Fig. 6, in which the brake drum *i* is grooved and carries in the groove the helically coiled metal band *o*, which is held at one end by *w* and tightened by a pull on the other at *d*. Because the motion of the wheel *a* tends to wind the band tighter as it turns in the direction of the arrow, this type of brake gives an exceedingly powerful effect with a comparatively light tension, but a great objection to it is its poor holding quality when the wheel turns in the reverse of its normal rotation.

Expanding Brakes differ from constricting brakes in that the friction members are inside of the brake drum and come into action by expanding against it instead of being constricted upon it. Such a brake is shown in Fig. 3, in which the friction ring *m* is enlarged in diameter and thus forced into contact with the drum *i* when the lever *h* is moved by a pull upon the rod *h*. This brake is open to the same objection that applies to the constricting brake last mentioned, which is that it is single acting and therefore of somewhat problematical efficacy for stopping any rearward motion, especially in such a case as that of a car backing down

hill through injury to the propelling mechanism. The brake pictured in Fig. 4 is a double-acting expanding brake, so will hold against either forward or backward movement. Its principal operating members are the two shoes *m m*, spread apart by the toggle joint *n*, so it is in a manner analogous to the constricting brake shown in Fig. 2. A very satisfactory and much used type of expanding brake is illustrated in Fig. 4, in which the expanding ring *m* is applied to the drum *i* by a separation of the ends caused by the action of the cam *n*, operated by the lever *h* and the rod *d*.

Disk Brakes are less common than disk clutches, but their very obvious superiority in a number of minor respects causes their occasional application to cars of proved quality. Fig. 7 shows a disk brake of a successful form, which differs little from the ordinary disk clutch. The hub drum *i* is formed with a series of grooves in the inner surface in which a series of steel rings are held by lugs projecting from the peripheries. Alternating with the steel rings is a series of bronze rings, similar, except that in their case the lugs engage with grooves formed in the inner drum *o*, which cannot rotate, though it is free to slide endwise on the axle. The spring *p* ordinarily holds the brake disengaged, but by pulling upon the wire *d* the bell crank *d* presses both series of disks into contact, and thus exerts a powerful retarding effect on the wheel.

Sprags of various sorts are much used to safeguard automobiles on hills. A sprag, in its simplest form, is simply a sharpened rod hinged to the underbody of the vehicle, so that when dropped it points rearward and digs into the road upon any rearward movement. More recently the ratchet sprag is coming into vogue. In this form it consists of a pawl acting on a ratchet affixed to the rear wheels or in some part of the transmission, so that the car cannot back unless the reverse is engaged.

Adjustment of Brakes.

Non-Compensated Brakes are on the order of the one sketched in Fig. 8, in which *i i* are the brake drums, within which the brakes are applied by movement of the levers *h h*. These in turn are pulled by the rods *d d*, which connect with the rod *c*, rocked by the brake lever *a*. It will be noticed that *d d* are

broken in the middle by turnbuckles by which they may be lengthened or shortened, so as to produce even application of both brakes. It is very important that this adjustment be correct, since if one of the rods is too short the application of the

brake with which it connects will prevent the application of the other. To get the adjustment right, it is sufficient to see that both rods are about equally tense when the brakes are lightly applied.

Compensated Brakes insure substantially equal braking on both wheels, regardless of the adjustments. A well-tried form is that shown in Fig. 9, in which the levers *h h* are both connected with *c* by a single wire cable which passes through the inside of *c* in such a manner that the tension upon it automatically keeps it shifted to an equilibrium of pull on both sides. Another compensated brake is shown in Fig. 10. In this the rods *d d* extend

only to the single tree *f*, which in turn is attached by the middle to *g*, connected with *c*. Obviously, the slight rock of *f* which will occur if *d d* are not the same length, will fully compensate the pull. The construction shown in Fig. 11 substitutes for the long

FIG. 7.

single tree of Fig. 10 a short one, at *f*, Fig. 11, which spans the two inner levers on the extra shaft *j j*. The action is similar to that of Fig. 10. It is not to be supposed that compensated brakes do not require adjustment. In common with brakes of all other types, it is exceedingly important that they be in such condition that they release freely and yet apply fully before the controlling lever or pedal reaches the limit of its movement. Many brakes violate the first of these conditions, and when they should be off, continue to drag on the drums, causing undue noise and wear. The spring *p*, Fig. 5, is a provision to insure quick release, and something of this sort is in almost every case desirable.

Friction Surface of Brakes are their most vital feature, for it is upon the quality and durability of these surfaces that the utility of a brake depends. Almost every conceivable material

FIG. 8.

FIG. 9.

has been tried for this service, but the best results are secured only with a few. Brake drums are almost invariably made of steel, though cast iron is used to some extent. Bronze shoes work very well on steel drums and a lesser degree of success has attended the use of copper or brass blocks against steel. Bronze and steel are practically the only materials used in disk brakes. Leather forms a friction surface that applies smoothly and retards effectively, but it is less durable than vulcanized fiber or a widely-used prepared belting, known by the trade name of "camel's hair." Castiron-to-castiron or castiron-to-steel make excellent brake surfaces—much better than is commonly supposed. All brake surfaces are subject to wear and this wear is to be reckoned with rather than avoided. Its occurrence constitutes the chief necessity for occasional readjustment and regularly requires absolute replacement. Provision for such replacement is made in all good designs, and with any well-built car it is not

FIG. 10.

FIG. 11.

very difficult to remove the worn friction surfaces and replace them with new. Usually this will involve a readjustment of the other parts of the brakes to make the moment of application coincide with the proper position of the lever or pedal.

Overheating of Brakes is a common difficulty, especially in coasting down long hills. Some brakes are air-cooled by fans and fins cast in the hub drums; others are water-cooled by drip devices arranged to be turned on when occasion requires. It is quite impossible to secure a braking effect without the development of heat, so this phenomenon is to be reckoned with. With cars provided with more than one set of brakes, application of the two should be alternated during long coasting.

Placing and Protection of Brakes are important details. Most modern cars have several sets—at least one acting on the rear-wheel drums, one acting on the propeller shaft or counter-shaft, etc. Some of the most-approved designs have both brakes acting in separate annular parts of the rear-wheel drums, a construction that is as neat as it is effective. Internal-expanding brakes are perhaps the easiest to protect, their nature making easy a construction that excludes mud and dust. Disk brakes are similarly easy to protect. Constricting brakes usually are left to get dirty and are of such construction that a little dirt possibly improves rather than harms their quality.

Control of Brakes.

Automobile brakes control either by pedals or levers—the former being most favored for running brakes and the latter for emergencies. A forwardly-moving lever is shown in Figs. 8, 9, 10 and 11 of this article, it being arranged to lock in any position on the sector *h*, by the detent mechanism. Pedal brakes rarely are arranged to lock in the applied position, though the auxiliary latch pedal for this purpose has enough advantages to make its use a cardinal tenet with some advanced manufacturers.

Power Control of brakes is an alluring proposition, and there are several devices on the market for working brakes by compressed air, spent exhaust gases, etc.

It is a great mistake to stop a car so suddenly as to slide the wheels. A gradual retardation of the wheels' rotation not only saves tires and trouble; it actually stops a car more quickly.

Remodeling Brake Systems.

Remodeling brakes is not a difficult task for the amateur, and is excellent policy with a car the least out of date. As has been suggested herein, the changing from one type of brake to another, the provision of compensating means, the fitting of a ratchet or other sprag, the renewal of friction surfaces, the installation of a brake-cooling system, modification of the control, etc., are all or any likely to improve a car not already up to date in every particular.

INTERNAL COMBUSTION ENGINE FOR SHIPS.

Next to the steam turbine, the internal combustion engine is the most interesting feature at present in the field of marine engineering, says the annual report of the *Institution of Naval Architects*. Although no very remarkable developments have taken place since I last addressed you from this chair, the use of this type of engine for marine work in small craft of various kinds has continued to make good progress. Its popularity for pleasure boats and launches continues to spread, while for commercial purposes engines using heavy oils and running with great economy and regularity are now being turned out by a number of firms. In our submarines the gasoline engine continues to be used for surface propulsion, and one of last year's additions to our fleet of torpedo boats was an experimental one 60 feet long, built by Mr. Yarrow's firm at Poplar, and propelled by three sets of internal combustion engines, each driving its own screw. The speed of this boat was 25 1-2 knots, which was 5 1-2 knots faster than that which would have been reached had steam machinery been installed. It is not, however, to gasoline engines that we can look for the propelling machinery of vessels of any considerable tonnage, the costly nature of the fuel puts it out of the question; and, so far as we can see at present, ordinary kerosene stands only second in this category. The application of the suction gas producer to marine practice, however, affords hope of using our cheapest fuel, coal, without the intervention of the steam boiler. The elucidation of this problem is beset with difficulties, but many able minds are at work upon it; and after the start that has been made with the experimental boats, of which we heard some account last year, we may reasonably hope for further interesting developments in this field of enterprise at no distant date. Already we hear rumors of a suction producer and gas engine of power sufficient to propel a seagoing vessel of large size.

HORSEPOWER IN RELATION TO MOTOR DIMENSIONS*

By F. W. LANCHESTER.

THE foundation argument of the present paper is based on *Dimensional Theory*. It has for many years been a surprise to me how little the theory of dimensions is known, much less employed, by engineers, and if, in the present paper, I can bring it home to some few here that there is a valuable tool lying idle which is worthy of frequent employment, the time taken in the preliminary discussion of *method* will have been in no sense wasted. The past neglect of dimensional theory by the engineer seems all the more inexplicable when we remember how, in other matters, discovery and method are taken "red hot" from the physical laboratory and adapted post haste by the modern engineer to meet the insatiable demands of Western civilization.

The Theory of Dimensions.

The theory of dimensions may be said to be founded upon the very simple and obvious fact that a *time* can never be equal to a *volume* or *space*, or an *area* to a *linear* quantity, or generally one physical quantity to another involving different fundamental quantities. The question of what constitutes a *fundamental quantity* touches on the ultimate definition of our conceptions; but it is customary to recognize *three fundamental quantities*, and three only. These are: *Length*, *Mass* and *Time*, or, for short, L., M. and T., into which all other physical quantities can be resolved. The expression denoting the constitution of any derived quantity is said to give the *dimensions* of that quantity. Thus, velocity is a length divided by time and

has the dimensions $\frac{L}{T}$; *acceleration* is velocity generated per

unit time, or $\frac{V}{T}$, ultimately $\frac{L}{T^2}$, and so on.

It is a necessary property of all equations representing physical quantities that the *dimensions* of the two sides are in agreement. We often find an expression that apparently falsifies the above statement, but such expression or equation is always *incomplete*—there is something *left to be understood*, such as a physical quantity *included in a constant*. Thus, if I say that the acceleration produced on a motor vehicle is proportional to the force that produces it, I may write the statement in the form of an expression: $f=cF$, and where f is acceleration, F , force, etc., is a constant. Now this seems a perfectly clear statement properly expressed, but we have dimensionally:

$$\frac{L}{T^2} = \frac{ML}{T^2}$$

and the dimensions do not balance; *there is an M on the right-hand side and none on the left.*

Now, what does this M mean. It means that my equation is not complete. The acceleration is produced on a given motor vehicle. It is not *any* motor vehicle—a general expression that covers everything from an omnibus to a basket perambulator; it is a *particular* motor vehicle, and dimensional theory says: "I want to know *how much that vehicle weighs.*" You see it does not want to know the make of the tires or the cylinder measurements. It tells us precisely what is missing to make the expression complete; it wants to know the *mass*.

An engineer should acquaint himself with the *dimensions* of the physical quantities with which he has to deal, and should make a habit of checking his equations whenever in doubt. Mistakes may easily occur owing to the employment of an *incomplete* expression in cases where the *complete* expression is neces-

sary. The method of *dimensions* will unfaillingly point out a missing factor or a mistaken quantity, if such exist.

Similarity of Figure and Its Consequence.

Before proceeding to the main discussion, there is a further preliminary matter to which it is necessary to devote some attention, *i.e.*, the question of *geometrical similarity* in bodies of varying size.

Let us take for discussion the case of a rectangular brick. We know that the volume of such a body, taking volume as a quantity we wish to investigate, may be expressed as a function of its three linear measurements, no matter what the proportions or size of the brick may be. If we know these measurements we can at once calculate the volume.

Now, owing to the simplicity of form of a brick we lose sight of an important point. We can define a brick by three measurements, but we cannot so define the volume of an irregular form. There is, however, another way of expressing the volume of a brick; we might take any one measurement, l as representing the *size* of the brick, and a co-efficient c as proper to the shape, thus:

$$\text{Volume} = l^3 \times c.$$

Then the co-efficient depends upon the *shape* of the brick, and is constant for bricks of similar geometrical form.

We thus have the volume expressed as a *function* of the *linear size* and the *geometrical shape*, and in this form the expression is applicable to any and every form of body from an Atlantic liner to a vegetable marrow. Now, so long as c is constant, that is to say, so long as we are dealing with bodies of geometrically similar form, we know, without elaborate measurement, that the surfaces of the different bodies are in the relation of their values of l^2 because they are *surfaces*, and the dimensions of surface = L^2 ; likewise, we know that the volumes are as l^3 because they are *volumes*, and the dimensions of volume = L^3 .

Further, if the *distribution of matter* in the bodies is geometrically similar, that is to say, if the bodies are *homomorphous*, as when all are of the same density, or being of not uniform density are of like density in like parts; the masses will be in the proportion of $p \cdot l^3$ for density, (p) is of the di-

$$\text{mensions, } \frac{M}{L^3} \text{ and } \frac{M}{L^3} \times L^3 = M.$$

Thus, we know that if two machines, say motors, be built part for part alike, but differing in *scale*, their weights are as their respective *linear measurements cubed*. Now this is an ordinary everyday fact with which every engineer is acquainted, and may be looked upon as a mere matter of common sense, but, like many other matters of common sense, it is only one step removed from the abstruse.

Power as a Function of Linear Measurement.

The maximum power capacity of an engine is likewise a function of its geometrical form and its linear dimension. Taking as before geometrical form as constant, that is, assuming geometrical similarity, let us investigate *power* as a function of linear measurement, l . We know that one of the determining factors in the power developed by an engine is the revolution speed, and we must first prescribe the general conditions that determine the maximum revolutions at which an engine can be run. We know that, given adequate port areas, the limit of speed is determined as in structures of all kinds, by the *strength of materials*. We are not justified in stressing the material in one machine any higher than the similarly situated part in another; our limiting condition is therefore *stress*, $r = \text{constant}$. If we assume the same materials to be used in dif-

*Paper read before The Institution of Automobile Engineers, London.

ferent machines, we have p also constant. There is no need, however, to remove these factors from the equation; we might want to employ different materials having different strengths and densities. Let us take p , σ and l as the variables on which the h.p. depends and deduce the general expression.

We have—

$$\text{H.P.} = l^p \times \rho^q \times \sigma^r \times \text{constant},$$

or dimensionally,

$$\frac{ML^3}{T^3} = L^p \times \frac{M^q}{L^{3q}} \times \frac{M^r}{L^r T^{2r}}$$

Whence,

$$\begin{aligned} q+r &= 1 \\ 2r &= 3 \\ p-3q-r &= 2 \end{aligned}$$

from which we have:

$$\begin{aligned} r &= 1.5 \\ q &= -.5 \\ p &= 2 \end{aligned}$$

so that the full expression is:

$$\text{H.P.} = \frac{\sigma^{1.5}}{\rho^{.5}} l^2 \times \text{constant.} \tag{1}$$

We will proceed to discuss the consequences of this result.

Deductions from H.P. Equation for Similar Engines.

In the first place, we will suppose that the same material be used in different cases for like parts; we then have ρ and σ constant, and:

(a) The power varies simply as the *square of the linear dimension*. Such linear dimension may be the *stroke* or the *cylinder diameter* or any other datum, provided the same similarly situated measurement be taken in every case.

(b) If the basis of measurement be two linear measurements (such as bore and stroke), the rating measurement may be the simple product of such measurements or the *product of their fractional powers*, provided the *sum of their indices = 2*, that is to say, so that the product shall be of the *dimensions L²*. Thus, if D be the diameter and S the stroke, the rating measurement might be D.S or D^{1.5}.S^{.5} or D^{1.1}.S^{.9}, etc., or generally—Dⁿ.S²⁻ⁿ. (2)

Corollary, that for engines of other than similar geometrical proportions, the same law applies, the values of the respective indices being chosen according to principles not so far investigated, for we may regard the similarly proportioned engine as a special case to which the general law must conform.

(c) That the *weight per h.p.* of similarly-designed engines varies *inversely as the linear measurement*. A most important consequence, as pointing out the essential saving of weight resulting from small units and multi-cylinder engines. Example: A four-cylinder engine, with 5" X 5" cylinders is (fly-wheel apart) of but one-half the weight of a proportionately-designed single-cylinder engine of the same power, *i.e.*, one of 10" diameter and stroke.

(d) With certain reservations, that will be discussed later, no horsepower rating rule is defensible that does not conform to the L² law; that is to say, being based on linear quantities, the sum of the indices must equal 2.

Universal Character of the L². Law.

It is a remarkable fact that the h.p. varies, as L² law here deduced seems to be almost, if not quite, universal. Thus, the h.p. capacity of an animal, other things being equal, depends upon the oxygen supply, that is to say, it is proportional to the *area* of lung membrane, and in turn to the cross sectional *area* of the aorta, etc. Again, in the case of the railway locomotive, the limitations to the h.p. are, the grate *area*, the heating *surface*, the sectional *area* of the steam pipe, etc., etc. It is never a *volume*, as the *volume* of the fire-box, or the *volume* of the boiler.

At one time I was disposed to attribute this generalization M.L³
to the fact that the *dimensions of power* involve L³ thus, —; T³

but any such explanation is inadequate, for *energy* also involves the same linear power, and energy is always measured by the *mass*, or under certain restrictions the *volume* of the determining factor. Thus, the heat energy released by the combustion of a quantity of coal depends upon its *mass*, but the power developed is proportional to the rate of combustion, and so, other things being equal, to the total *surface* of the incandescent lumps of fuel.

It would seem probable that the considerations that apply in the case of a machine producing or transmitting mechanical energy, as herein demonstrated, where the conditions are regulated by the factors stress and density, also obtain over a much wider range of conditions, including the production or transference of energy in other forms, such as the production of heat by combustion; this aspect of the subject is outside the scope of the present paper.

To Include Changes of Geometrical Proportion.

The comparison of the power capacity of different engines, when the condition of similarity is infringed is, in reality, a highly complex problem, for the reason that we now have to deal with h.p. as a function of *geometrical form*, and the possible forms of change are multiplied infinitely. If the problem were presented in its widest mathematical sense, as supposing engines *proportioned by pure chance*, then the position might be considered hopeless. In reality, the issue is brought within very narrow limits by the assumption of a certain degree of skill on the part of the designer, and other considerations of a practical nature.

There are many factors that may independently limit the h.p. of an engine, on the principle that the strength of a chain is its weakest link. For example, a restricted port or valve area may limit the h.p. to vastly less than that legitimately due to the cylinder measurements. By common consent, it is agreed that the cylinder measurements form the most suitable basis for rating purposes. Whatever basis be chosen, we shall expect the *rating rule* to have some influence towards *distorting* the design as due to natural evolution; for instance, if we were to take the valve or port area as basis, the designer would be tempted to cut this down as much as possible, and a highly undesirable kind of *distortion* would come into vogue, resulting in great loss of efficiency. In choosing the cylinder measurements the tendency is in the opposite direction; *i.e.*, the ports are made as free as possible, which, inasmuch as it tends to efficiency, may be looked upon as a fault on the right side. It must be understood that there is no *strictly scientific* reason why the cylinder measurements alone should be taken as the basis, it is a matter of convenience or common sense; the tacit assumption is made that the other determining factors are so dealt with that their effect is negligible,—it is for the designer to see that this tacit assumption is complied with.

Having determined on cylinder measurement as a basis, it remains for us to investigate the conditions controlling the index values in the expression DⁿX S²⁻ⁿ, so that the designer, under the rating rule, cannot gain by adopting extreme proportions; that is to say, so that the rule adopted will not result in any distortion of the design in respect of the proportions of stroke to diameter.

(To be continued.)

The action of oils on vulcanized rubber is a subject which is much misunderstood generally. Thomson did some splendid work on the subject some years ago, but since then no great progress has been made. He found that rubber threads treated with a small quantity of oil preserved all their properties. With a larger quantity oxidation set in very quickly. Coconut and palm oil acted the most energetically; castor oil had the least action, and is one of the few not harmful to rubber.

WHAT AUTO INVENTORS ARE DOING ABROAD

IN the construction of ordinary wooden artillery wheels the spokes are placed, as is well known, radially to the hub, where they are in a position which has hitherto been considered the best if not the only possible one for them to occupy under the circumstances, says the *Automotor Journal*. The spokes of wooden wheels are, of course, in compression, in which respect they differ from those of the wire wheel, which are in tension,

TANGENT SPOKE AUTO WHEEL.

and which are in consequence arranged tangentially to the hub. To place wooden spokes tangentially to the hub, therefore, is essentially a radical departure in wooden wheel construction, but it would appear from the success which has so far met the production of the tangent wheel shown in the accompanying illustration, that there is a good deal to be said for this method of arrangement. On the wheels made by this firm the spokes have wedge ends, instead of being turned down into tangs, and at the hub these wedges lie close up against one another to form a solid boss similar to that of the ordinary artillery wheel, except that the center lines of the spokes are tangential instead of radial. At their outer ends the spokes are wedged into the felloe so that they obtain a bearing surface across their full width. Among the features claimed for this principle of construction are that it gives greater resiliency and longer life to the wheel. The increased resiliency is attributed to the spokes bending slightly under sudden shocks, while longer life is claimed to result partly from the increased resiliency and partly from the reduced effect which shrinkage in the spokes has on the wheel as a whole.

Some Detailed Refinements of the Adler.

In addition to displaying that painstaking thoroughness that is characteristic of the Teuton, the German automobile builder has also demonstrated that he is not behind his confrères of any other nation in devising those refinements of detail that add to the convenience and safety of the car in operation. The Adler, which was prominently staged at the recent London show, affords an excellent example of this. As an instance, there may be cited the use of a toe pedal for admitting fresh water to the cooling jackets of the brake drums, this pedal being part of the regular

FIG. 1.—Concealed reverse trigger.

FIG. 2.—Toe pedal to admit water to brake drum

NEW DETAIL FEATURES OF THE ADLER CAR.

brake pedal, and may be brought into action together with the latter or not, as desired, a slight change in the angle at which the foot is held in braking being all that is required. The con-

nections of the device are clearly illustrated in the accompanying sketch from *Motor* (London), to which we are also indebted for those of the Adler concealed reverse trigger and the Nacke hand adjuster for pedal brakes. As will be plain, the water cock of the oscillating type is attached to the frame directly behind and in line with the brake pedal.

The illustrations of the concealed reverse trigger are practically self-explanatory. Under ordinary running conditions, a cap covers the reverse trigger, so that it is impossible for it to be inadvertently depressed. This cap is sufficiently close-fitting not to be disturbed by the jolting or vibration of the car, but readily yields to the fingers. When thrown back, the trigger may readily be depressed the same as though no safeguard were provided. The device represents an added touch of refinement to the various methods of preventing the accidental use of the reverse gear ordinarily employed on the majority of cars.

A Very Convenient Method of Brake Adjusting.

It must be admitted even by the designer himself that there is yet considerable room for improvement in the way of facilitating means of adjusting a number of the essential parts of the average car. Naturally the millennium is represented by a car on which most of the adjustments could be made by hand, and at most the only tools needed would be a single wrench, a screw driver and a pair of pliers. That there is a more or less pronounced trend in this direction is quite evident from the number of devices brought out from time to time with this end in view. One of them that has attracted a deserved amount of attention is the Nacke hand adjuster for drum brakes of the type universally used on cars. This first made its appearance about a year ago, and has been adopted on some of the Italian cars. As the surfaces of the brake bands wear it is possible to make them snug again merely by a quarter turn of the handwheel, which automatically locks at each quarter turn unless held out of engagement by the notches shown; a helical spring maintains the adjustment wherever set.

NACKE PEDAL BRAKE ADJUSTER.

A Novel Type of Shock Absorber.

The Simplex Shock Absorber is devised to be interposed between the axle and the carriage spring, a set of four on each car thus absorbing the first portion of the shock from the road, says *Motor* (London). The device is shown in elevation and part section in the diagram. It will be seen to consist of an external box, which carries the carriage spring. Attached to the axle is the interior box, and between the two is the pneumatic cushion which acts as the absorber. The two boxes have extensions between which are steel friction rollers (lubricated with dry graphite) for the purpose of guides. When the cushion is inflated to a pressure of about 10 pounds to the square inch it will carry a load of 500 pounds. If the load per wheel is heavier than this the pressure may be slightly increased or an absorber of slightly larger dimensions can be employed. The pressure can easily be regulated to suit the character of a district. Should the cushion deflate (the likelihood of which is small), the outer box settles down on the axle and the position is thus as if the spring were rigidly bolted to the axle. One of the ends has a plate which is readily removable for the purpose of replacing a cushion.

The device is well worthy of careful inspection. It is shown complete, dismantled, and also fitted on a car on which it has been tested over a considerable distance.

Differential Locks Used on Steam Trucks.

The commercial section of the Agricultural Hall show recently held in London brought forth a representative showing of what would be called traction engines in this country, but which the

A NOVEL FORM OF ENGLISH SHOCK-ABSORBER.

Englishman dubs a "lorry." Like our road rollers and plow-pullers, by far the greater number of these lorries are driven by steam and always have been. In fact, they are an ancient and well-established institution in England for heavy haulage, having existed prior to that abortive piece of legislation that barred the public roads to anything that moved under its own power, unless it went on legs. This accounts for the large number, as well as the wide diversity in which these vehicles were exhibited.

One of their features that is bound to catch the eye of the automobile sharp is the provision for locking the differential that is made on some, if not all of them. Just why the differential should be put out of action does not appear at first sight, but it is evident that the needs of a slow-going two to five-ton truck, or a tractor that may be pulling two or three times this weight behind it, are quite different from those of the swift-traveling automobile. The employment of a means for locking the differential gives all the advantages of a rigid driving axle when traveling straight ahead, and the driver always has plenty of time to operate the release gear before taking a turn. Two forms of the method employed for effecting this end are shown by the accompanying sketches. One, shown on the complete wheel, is termed the "Sentinel" differential lock, and consists of a pawl and toothed wheel, while the other, known as the "Mann," partakes

TYPES OF DIFFERENTIAL LOCKS USED ON ENGLISH LORRIES.

of the nature of a brake band, and is probably operated from the seat of the lorry by similar means—i.e., a small hand lever or pedal. In the case of the former, the pawl is fastened to the wheel and the toothed or starwheel to the rear axle, so that the device as a whole constitutes the simplest form of differential possible. For rounding a curve the pawl is pulled out of engagement, permitting its driving wheel to run free of the axle, all the power being transmitted through the other wheel, which is rigidly fastened to the axle. This gives a positive drive when in action, which would not appear to be the case with the Mann with its drum and brake band.

THE GASOLINE FAMINE.*

By L. BAUDRY de SAUNIER.

It appears that we are in danger of dying of hunger in the person of our motors. The liquid food which, vaporized and mixed with air, gives them force, is getting scarce. Week by week the rates for modern oats are rising. The reason is simple: automobiles are already too numerous. As the production of gasoline is necessarily limited, there is an eager demand for the barrels, and rates rise. A day will come when the countries producing gasoline will keep it all for themselves and we shall have no need to show eagerness.

But why is the production of gasoline necessarily limited? It is because gasoline is distilled from petrol, when the petrol contains any, for all petrols do not contain the precious liquid. Russian petrols contain next to nothing; American mineral oils give about 10 per cent; Indian petrol about the same, and Roumanian petrols contain 20 per cent. of gasoline. That is all there is.

The producer says, "You will evidently take all the gasoline I can produce, but will you also take the kerosene, the heavy oils, the greases, etc., all products of the distillation of petrol in company with gasoline, and which are produced in much greater quantity than gasoline itself? What shall I do with these? You do not ask for them at all in the same proportion as the gasoline."

In this state of affairs we turn towards alcohol, the alcohol which is to be found in our beetroots and our potatoes. I believe that in a not very distant future our internal combustion motors will be fed on alcohol. Examples of its application for our purposes are already encouraging. But we must not forget that they are only encouraging, and that everything has yet to be done to make alcohol as practical for us as is gasoline.

But is alcohol any cheaper than gasoline? No; per gallon it costs a trifle less, but we consume more. Pour it into the tank. What is this? A few drops have fallen on the paint and as many holes have been formed. Yes, alcohol dissolves paint. This is a grave defect that workshop experiments do not reveal, but which good solid practice brings to light instantly. We look glum.

Try to crank your engine. Not a bit of it. No more explosions than in a coffee mill. The motor must be warmed before it will run on alcohol. In other words, we must start with gasoline. We are off, but what a smell. It is the benzine that is burning, the benzine mixed with the alcohol to form a carburant.

We stop and examine the motor. The valves are red; the valve seats and the combustion chambers are red. A few hours of this and our engine will be paralyzed. Sorel, one of our best chemists, and one who has most closely studied this question, says that the fault is with the methylated spirits with which the authorities poison our alcohol in order that we may not drink it. As soon as the combustion is imperfect alcohol with methylated spirits is transformed into formic aldehyde or "trioxymethylene." And that is why our alcohol motor remains silent. Combustion is imperfect the moment gasification is not absolute. A carbureter which is satisfied to pulverize the liquid as our present carbureters do is deplorable when used for alcohol.

Before crying "Gasoline is dead, long live alcohol," it would be well to ask the one most interested, the engine of your automobile, what he thinks of it. Prove to a horse by most scientific calculations that wood shavings are the most modern food for the equine race, the fashionable food which ought to be in every hayrack, and he will die nevertheless, unless you know how to prepare your shavings so that they can be assimilated by his stomach.

There is certainly a brilliant future for the alcohol motor, since the liquid possesses the most precious qualities. But we should not try to foolishly convince ourselves that it is at present suitable for our motors. Everything has to be created: the carbureter which will carburete perfectly, an ignition which will fire the charge punctually, the motor itself which will use the entire practical portion of the explosion. Until that is arrived at we shall have a series of interesting experiments and a re-edition of races and industrial tests such as we have had for the last ten years.

*Translated from "Omnia" by W. F. Bradley.

LETTERS INTERESTING AND INSTRUCTIVE

Kerosene and Alcohol as Emergency Fuels.

Editor THE AUTOMOBILE:

[726.]—It being a matter of interest to me, and doubtless to others, I will be glad to have your advice as to the use of kerosene oil and alcohol in gasoline motors. Say, for instance, a party is on a trip and gasoline runs out from accident or oversight. Kerosene or alcohol can be secured almost anywhere, and I would like to know just how and what use can be made of each and how best to use them. It is a Cadillac single-cylinder 1906 Model M I am using.

ENQUIRER.

Rowland, N. C.

In an emergency such as you mention, either alcohol or kerosene may be used as fuel without any great difficulty and without making any alteration to the engine. This will be the case particularly if the engine happens to be running when the shortage of fuel is discovered, as it will then be hot, and may be started on the new fuel without any great trouble, or, better still, may be kept running merely by pouring the new supply into the tank. If the engine has stopped and cooled off, there will be more or less difficulty experienced in getting it under way again on either alcohol or kerosene, but once started it should be easy to get home. As both of these fuels require considerably more heat to properly vaporize them than gasoline does, the operation of the motor will be greatly improved when using them by conducting as much hot air from the exhaust as possible round the carbureter, beside using hot air for the mixture.

In case the engine has cooled off and will not start on the new fuel, the best method of facilitating this is to procure some hot water. Take some old rags or waste, soak them in the water, and swathe the carbureter with them in order to raise its temperature as much as possible. The rags will be preferable owing to the danger of getting lint into the carbureter when using waste. Vigorous turning of the crank will assist the vaporization. If a down-grade be handy, let the car roll down it, and when some momentum is attained ease in the clutch gently on the high gear. Owing to the greater suction exerted on the carbureter by the engine under such circumstances, this is an expedient that seldom fails to start it, other things being in order. Failing the convenient hill, a few husky men or a horse to get the car rolling will suffice. Never use anything but the high gear or direct drive and ease it into engagement very gently; throwing in the low gear will bring the car to a sudden stop on the level, or impose a terrific strain on the transmission if the car happens to be coasting.

Why One Cylinder Fired Louder than the Others.

Editor THE AUTOMOBILE:

[727.]—In response to request contained in letter No. 698: The trouble which caused the louder exhaust in one of the four cylinders of my engine was in the hammer vibrator spring, which I conclude was too stiff to admit of its being perfectly adjusted, and I think on this account only fired part of the charge in that cylinder. I had previously put in a new contact spring which did not remedy the trouble, but upon putting in a new hammer spring the trouble was immediately overcome and each exhaust from the four cylinders is now perfectly equal in sound again.

Westfield, Mass.

LELAND M. GILMAN.

While the lag in one of the coil vibrators may have been responsible for the uneven firing of one of the cylinders of the four-cylinder engine in question, your conclusion that the greater amount of noise developed arose from the fact that only part of the charge was fired would hardly appear to be correct. If less than the normal charge were being fired by that particular cylinder there is good reason to believe that the sound would have been less rather than greater than that of the other cylinders. What was probably the case, in view of the fact that the change to another vibrator cured the trouble, was that the lag delayed the explosion enough to destroy the sequence and the late one was emphasized by occurring slightly out of time.

Concerning the Worm Gear Type of Drive.

Editor THE AUTOMOBILE:

[728.]—I note in the April 4 issue of "The Automobile" an illustration of a Franklin truck Type J, with a worm and gear drive. Can you give me any additional information regarding other users of the worm and gear drive, also reference to any tests of well-designed worms and gears? Any information you may be able to give me on this subject will be appreciated. I find your publication of great value as well as interest.

F. M. COCKRELL, JR.

Warrensburg, Mo.

Beside the Franklin truck you mention, the Mitchell commercial vehicles also employ the worm gear type of drive and have done so for more than a year past with considerable success. We do not know of any other automobile builders in this country at present using this type of drive, but understand that several are at present experimenting with a view to its adoption. Abroad, the Dennis buses have used it for two years or more, very successfully, we believe. The efficiency of the worm and gear drive is relatively low, and, unless properly designed and well made, very low, so much so in fact as to preclude its use. The amount of loss through friction naturally varies with the pitch as well as the velocity at the pitch line. With the latter at 100 feet per minute, a worm of 10 degrees pitch gives an efficiency of 82 per cent. as compared with 98 per cent. for spur pinions and .955 per cent. for 45 degree spiral pinions. Increasing the velocity to 200 feet per minute with the same pitch as mentioned, gives an efficiency of 86 per cent.; with worms of 5 and 7 degrees, respectively, the efficiencies are .765 and .815 per cent. respectively at the same speed. The tests from which these data were obtained were made on ordinary machinery at low velocities, and consequently have little if any bearing on the use of this type of gearing on the automobile. Marsh, Williams & Co., Philadelphia, Pa., are makers of this class of gears and will doubtless give you any detailed information you wish.

Poorly Aligned Gear Shafts Cause Binding.

Editor THE AUTOMOBILE:

[729.]—Will you kindly publish in "The Automobile" a remedy for the following? I have a two-cylinder Clement-Bayard—a grand car in all ways, with the exception of the great rattle in the transmission gear case from the gears. It has three forward speeds, and sometimes when travelling on the direct drive or high-speed, I have a hard time to shift gears in order to stop. I have to exert all my strength against the shifting lever to get the gears out of mesh. The jack shaft is directly over the other shaft. Should the teeth of every gear be on a direct line with the others, so as to make a straight line? Also, could I use fiber gears? Could I use a little air pressure on my common gasoline tank, which is a trifle lower than the carbureter?

Hoping to see these questions answered in "The Automobile," which I read regularly.

C. W. BYE.

Corona, L. I.

It seems evident that one or the other of the shafts in the gear box has been sprung out of line, in all probability the jackshaft, or it may be that both have got out of line, which would account for the binding, as you mention disengaging calls for considerable strength. The teeth of all the pinions should be in an absolutely direct line, so that they will coincide when brought together, and when in this condition there is no difficulty in either engaging or disengaging the gears. Doubtless you will find that both the pinions themselves and the bearings of the shaft have become worn, the latter particularly being responsible for a great amount of chattering and rattling, as it permits the entire shaft to jump and bounce, according to the amount of play there happens to be. If the bearings are snug and the gears accurately aligned, we see no reason why the gearbox should make an unusual amount of noise, especially if the gears are kept properly lubricated. Fiber gears would never stand such service as the pinions in a change-speed gearbox are called upon to perform; they would go to pieces in a very short time. If the pinions in the car at the pres-

ent time are very badly worn, it will be necessary to replace them to make the car silent-running. Should the objectionable noise still continue after making the necessary repairs and replacements, as above suggested, we think the expedient commonly resorted to on electric street cars might be adopted to advantage. This consists of filling the gear boxes with a mixture of grease or heavy lubricating oil and sawdust. In your case it would be preferable to use jewelers' sawdust, which is very fine. This has been used with good success on old cars afflicted with trouble similar to yours, but it is a poor remedy at best to muffle the clattering made by a worn and badly aligned set of gears—correct these evils first and see if the one you complain of does not disappear with them before adopting this.

There is no reason why you cannot use air pressure on the tank now fitted on the car. Of course, it will be necessary to fill the air vent in the present stopper.

Annular Bearings for Thrust.

Editor THE AUTOMOBILE:

[730.]—In an ordinary annular ball bearing, of the Hess-Bright non-adjustable type, a suitable bearing to sustain thrusts? I have noticed numerous applications of this bearing to this character of service, but I cannot understand why it is well to use it so, when it is remembered that the same concern makes an excellent type of thrust bearing, especially adapted to its purpose.

Rochester, N. Y.

GEORGE A. ELLIS.

Annular ball bearings make excellent thrust bearings, and are perhaps rather easier to find space for in a given design than the more highly specialized thrust bearings. The fact that thus used they will take either thrust or lateral stresses is a point in their favor. Used for thrust it is customary to leave them free in a plane at right angles to the axis of the shaft, but to confine them closely in the other direction. Just the opposite applies to the same type of bearing used in the ordinary manner. It is well to bear in mind that when an annular ball bearing is used for thrusts, all, instead of one or two, of the balls are dividing the load, whereas with the same bearing under other conditions one or two balls must be capable of carrying the whole load.

Advisability of Solid Tires on Steam Runabout.

Editor THE AUTOMOBILE:

[731.]—I would like to know if it would be advisable to employ hard (solid) tires on a Stanley steam runabout. What other solid tire is made in the shape of a T, or along those lines, beside the Swinehart? Any information you or your readers can give me on this subject will be appreciated.

Newton Center, Mass.

C. C. BUTTS.

There is no reason why you should not be able to use solid tires on your car, particularly if the roads in your section are good, but it will be to greater or less extent sacrificing your comfort, as there is bound to be more vibration and more jolting felt with the hard tires than with the pneumatics. Your car is so light and easy running that we should hardly think the change worth while, and certainly would not recommend it. If you will equip your car with a good double-tube pneumatic tire of the proper size to carry its weight, you should have little or no trouble from this source. You will find the various makes of solid tires announced in our advertising columns.

Some Queries Concerning Compression.

Editor THE AUTOMOBILE:

[732.]—I would be obliged if you could give me in your valued paper some information re correct compression in cylinders. What would be good compression for a four-cylinder, 15-horsepower car having cylinders of 3 1/2-inch bore by 4 1/2-inch stroke? Also, has a car with larger cylinders greater compression? Of course, I understand the nearer the head of a cylinder the piston goes the greater the compression, but I take it automobile manufacturers all design engines so that pistons rise as high as possible in cylinders—so that need not be taken into consideration.

Toronto, Can.

P. C. LARKIN.

The correct compression in any motor cylinder would naturally be that for which it was designed, so what would be the correct compression for one would not be the same for any other except

of the same design, size and make. Sixty to seventy pounds to the square inch would be a good compression for a motor of the dimensions you mention to have an output of 15 horsepower at a speed of 1,200 to 1,500 r.p.m. or over. An increase in the size of the cylinders does not necessarily mean a corresponding increase in the compression. While the power for the same size increases with greater compression, there is not only a point where the benefit to be derived would be neutralized by the greater amount of power absorbed in overcoming it on the compression stroke, but also a point where it is no longer safe to carry the compression any further, owing to the danger of spontaneous ignition; with gasoline this is about 100 pounds to the square inch.

Automobile engines are not designed so that the piston rises as high as possible in the cylinder, nor for that matter are any internal combustion engines. A space known as the clearance is always allowed for, and the depth of this in connection with the design of the cylinder, valve pockets and the like governs the compression. This clearance or combustion chamber is usually calculated with reference to the length of the stroke, and ranges from about 20 to 35 per cent. of the latter, these figures probably representing the extremes in either direction. This part of the cylinder is generally counterbored to a slightly greater diameter.

Instruction Books Wanted by General Repairers.

Editor THE AUTOMOBILE:

[733.]—As there are a number of factories that make a business of repairing automobiles in addition to their regular work without having the agency for any particular car, we would like to ask if "The Automobile" does not think it advisable for the makers to furnish such repairers with their instruction books, as it would be a great help. We have more or less auto repairing to do here owing to the great number of break-downs caused by the state of the roads between Utica and Albany and we have come across cases where it has been necessary for touring parties to call the makers on the long distance telephone to find the correct setting of the valves, thus occasioning extra expense as well as delay.

We hope "The Automobile" will keep the execrable condition of the roads in this part of the State before the people; they could not possibly be worse and are a positive disgrace to civilization.

Fort Plain, N. Y.

ALPHONSO WALRATH CO.

We have no doubt that the makers of any particular car will gladly send copies of their instruction books to you upon application; by noting the particular cars most frequently met with in your part of the State and obtaining the instruction book of each you will have a library that should be of considerable assistance in making adjustments.

DARRACQ RACERS AND THE DIFFERENTIAL.

Editor THE AUTOMOBILE:

[734.]—We notice an article in your issue of April 23, being an answer to letter No. 722, written to David F. Ladin, regarding the racing cars constructed without differentials. The statement that the car with which Wagner won the Vanderbilt Cup race was constructed without a differential is a mistake. The car with which Hemery won the 1905 Vanderbilt Cup race was made without a differential, and likewise the 200-horsepower eight-cylinder car with which Demogest made two miles in :58 4-5 on the Ormond-Daytona Beach, January, 1906.

The 1906 racing cars which the Darracq company built, one of which Wagner drove to victory in the Vanderbilt Cup race, were all supplied with differentials. The 1907 cars being built for the Grand Prix race are minus the differentials.

DARRACQ MOTOR CAR COMPANY,

New York City.

G. M. MacWilliam, President.

PROPER SIZE OF TUBING FOR FLASH GENERATOR.

Editor THE AUTOMOBILE:

[735.]—I would like to hear from a number of steam users as to what size and weight of tubing has been found most serviceable, all things considered, in flash and semi-flash boiler practice. I think, from experiments last fall, that a moderately large tube is not a bad idea, since it gives the safety from leakage afforded by the water tube method and also more elasticity of control, as there is a considerable reserve, combining the best points of the water tube system with those which make the fire tube system desirable.

GEORGE A. HENDERSON.

Decatur, Ill.

EFFECT OF THE DIFFERENTIAL ON SKIDDING

By PAUL BARY, IN L'AUTOMOBILE.*

NOT long since there appeared in our columns an article criticising the use of the differential on automobiles on the ground that it facilitated skidding and side-slipping. There is an opinion in Germany, disputed, it is true, but also admitted at times, that the differential does appear in this pernicious rôle. In the present article there is set forth an opinion directly opposed to the foregoing, and which is quite convincing; we think, however, that the divergence of views is such that it is necessary for every one to form his own opinion from his personal experiences, as each of the latter occurs under special circumstances and in which observations may be rapidly made as all the circumstances are known. On the other hand, the observation in question is neither methodical nor systematic because the autoist has taken no pains to make it so, and in consequence the conclusions that may be drawn from it are of little or no value.

If it were possible to make a comparison between two touring cars the same in every respect, with the exception of the rear axle, which on one would be equipped with a regulation differential, and on the other with a friction or ratchet device permitting

1.—When traveling straight ahead. 2.—When rounding a corner.

DIAGRAM ILLUSTRATING THE FORCES INVOLVED.

the wheels to run at different speeds in rounding turns, the alternate use of these two vehicles on the same curves would constitute a basis on which to find for or against the differential. Unfortunately such a comparison has never been made so far as is known with gasoline vehicles; electric cars, whether with one or two motors on the rear axle, are hardly to be considered, as there is not sufficient difference between them where skidding is concerned. Nor do they run at sufficiently high speeds to make accidents from this cause at all frequent.

In consequence, it is necessary, in order to form an opinion in the matter, to discuss the causes that lead a vehicle to slide laterally in the line of the rear axle, and to ascertain if these causes are due to the differential or to some other part of the car. We will accordingly consider the car shown diagrammatically in the accompanying sketch, and will assume that the position 1 shows the car progressing at a certain speed and with all four wheels accurately in line; the driver then applies the brake suddenly. The moving mass of the car M with its center of gravity at G tends to continue in the same direction that it has been running, as indicated by the arrow F . Whichever brake be applied, and whether it results in the blocking of both rear wheels, or only one, or whether it be the pedal brake, nothing can change the direction of the force F tending to cause the car to continue along the same line. It is, in fact, evident that one wheel continuing to turn, whether on account of the lesser amount of traction, or on account of its brake band being much looser, the force continues to act in the line of F , since the force F_1 of that wheel is parallel to F and the angle w is inalterable.

What happens in actual practice, however, is that the vehicle is not always in a mathematically straight line, and the force F acts as a couple by reason of the immovable wheel O and the

product of the reaction in the direction which the driver is powerless to maintain completely. Hence the vehicle assumes the position indicated by 2, and the component of the slipping force $f = \frac{F}{\alpha}$ may attain considerable value.

The true cause of the side-slipping is to be found in the fact that the direction of the vehicle is influenced by this lateral force, and the steering gear is never completely free from this stress, nor is it completely irreversible; any one of these conditions completely fulfilled proves an ample preventive of skidding in a straight line. It is easy to recall experiences where, in operating the brake on one rear wheel, a strong tendency for the car to turn is felt, and if this comes as a surprise to the driver, as where the brakes are applied suddenly, it is impossible to recover in sufficient time to prevent it, and the vehicle slews right round.

We are reluctant to believe that the case cited in the former article referred to, that placing one wheel on good ground and the other on a slippery surface, is particularly conducive to side-slipping, since it may be said that this is really a condition chosen by so many automobilists, who place but one non-skid tire on the rear wheels, and who by that precaution are protected in the majority of instances from those ill-effects of side-slipping that result from the use of smooth tires. (This was a more or less general practice in Paris a year or two ago.)

It is true that up to the present we have not considered that special rôle of the differential which is illustrated where, with the cardan shaft held, one of the wheels is turned by hand, and the other immediately begins to turn in the opposite direction, the same action taking place in service where, with one of the wheels equipped with a non-skid tire, it continues to turn forward in the direction of the travel when the other is compelled to rotate in the opposite direction.

Again referring to the illustration, let us assume that one of the wheels is held at O and the axle is subjected to a force F_1 in a direction counter to that of F_2 . These two forces will produce a couple tending to cause the vehicle to turn about the center of the rear axle M , a movement that cannot be produced in traveling except by lateral slipping of the forward part of the car. This slipping not occurring, the simultaneous action of the two rear wheels turning in opposite directions will be without any direct effect; it will operate, however, as we have already mentioned above, in the direction of the forward wheels.

On the whole, we think the possibility of eliminating the differential forms an interesting subject for study, and its successful culmination would constitute marked progress, just as the abolition of such a relatively delicate piece of mechanism would from any machine, but unfortunately it would not result in the prevention of side-slipping and sudden slewing round, which with the present long vehicles can only be avoided with good non-skid bands and well-fixed steering gear.

TOTAL ANNUAL CONSUMPTION OF ALUMINUM.

One of the striking results of the great progress of the automobile industry has been the tremendous development of the manufacture of aluminum, of which some idea may be had merely by quoting a few figures. In France, no less than 35,000 horsepower are continually employed in the making of aluminum; Germany utilizes some 21,000 for the same purpose, the United States a like amount, and Scotland about 6,000 horsepower. This represents something like 82,000 horsepower in round numbers—an amount that can easily be doubled in the works now in existence. As each horsepower represents an annual output of 200 kilos of aluminum, it means that the total yearly production is something like 16,500 tons, of which 12,300 are produced in Great Britain and on the Continent of Europe.

STEERING GEAR WITH DISTINCTIVE FEATURES.

That a great deal of study has been devoted to the evolution of a form of steering gear designed along lines radically differing from those followed in current practice, in the making of the Marmon steering gear, will be evident at a glance at the accompanying illustration of it. A model of it with the aluminum housing cut away to show the interior was on exhibition at last

MARMON ADJUSTABLE ROLLER-BEARING STEERING GEAR.

winter's shows and received considerable favorable attention, particularly at the hands of designers and builders of cars. The casing is of cast aluminum and is made oil and dust-tight; it is filled with oil or thin grease so that all parts are thoroughly lubricated. The steering column is mounted on Timken roller bearings, one at the bottom of the aluminum case and the other at the top, thus supporting the screw and nut mechanism of the gear centrally between them. These bearings are adjustable by means of a single nut on top of the case. The steering arm, which is a one-piece drop forging, is also mounted on the same type of bearings and is adjustable in the same manner, the single nut being conveniently placed at one end.

The column carries a steel screw working in a large bronze nut having a lining of hard babbitt. Bronze pins, forming part of and extending on each side of the nut, carry slotted steel links, the lower ends of which are pin connected to the two arms of the yoke forging which is keyed to the steering arm. A wing segment in the center of the yoke forging works in a slot in the bronze nut, preventing the nut from turning and likewise relieving the links from twisting. Two set screws in the casing act as adjusting stops on the wing segment, thus regulating the extreme movement of the steering arm. With this arrangement the mechanism is held in perfect alignment.

This form of construction lends itself particularly well to the elimination of lost motion between the parts and only neglect in providing oil or very long continued use should bring it about, in which event the babbitted nut can be readily replaced with a new one at small expense. Though irreversible, the lever connections are so well proportioned with the size and pitch of the screw that the steering is very easy, giving that much desired "feel" of the road which is a characteristic of only a perfectly

balanced and easy working gear. The column has a stationary brass tube casing through which the rods of the spark and throttle control extend, being connected to two pin ratchet segments at the bottom of the case. A foot accelerator is employed to operate the throttle independently of the position of the lever over the wheel. The steering wheel itself is built up of black walnut segments on a solid three arm wheel casting, and is given a high polish in the natural finish of the wood. As shown, the entire column is mounted on a single tubular cross member somewhat after the fashion of a trunnion, permitting the slant of the column to be adjusted to suit the driver. Oil injected under the cap on the wheel lubricates all the moving parts of the column. The Nordyke & Marmon Company, Indianapolis, Ind., will make this gear a standard part of the equipment of their Marmon cars from now on.

SOME TESTS OF LUBRICATING OILS.

The diagrams herewith submitted show the results of a number of tests of lubricating oils, made by me some time ago, says A. L. Westcott in *The American Machinist*. The machine upon which these tests were made consisted of a shaft running in bearings on a machine frame, and carrying on one end a journal, running in a bearing the two halves of which were pressed together by a heavy spring. A lever arm, bolted to the bearing, was supported in a horizontal position at its outer end, on a platform weighing scale. The springs were carefully calibrated, so that the pressure on the bearing was exactly known. A suitable opening was provided in the bearing for the insertion of a thermometer. Oil was applied by means of an ordinary sight-feed oil cup, at the rate of about twelve drops per minute.

The journal was of steel, 3 1/4 inches in diameter and 8 inches long, and the bearing was of cast iron. The speed, in tests Nos. 1, 2 and 3, was 410 revolutions per minute; in Nos. 4 and 5, 500 revolutions per minute, giving surface velocities of 350 and 425

CHART OF LUBRICATING OIL TESTS.

feet per minute, respectively. The load on journal in all tests was 1,400 pounds, or 54 pounds per square inch of projected area.

The tests were about two hours in length, observations being taken of temperature and scales load every fifteen minutes.

The curves show, in general, a decreasing coefficient of friction with increasing temperature, up to 150 degrees; and the conclusion may be drawn that with the oils tested that temperature may be safely attained in practice without danger of seizing.

The sudden rise in curve No. 2, at 122 degrees, was caused by the accidental stopping of the machine at that point. It was immediately started again, and the next observation showed an increase from 0.015 to 0.020; but the following observation dropped back to 0.013. This indicates that, on starting, it takes some time for the film of oil between the bearing surfaces to become reestablished.

USEFUL FLUX FOR WELDING STEEL AND IRON.

The following flux is recommended by French engineers for welding steel and iron or steel to steel, says *The English Mechanic*: Borax ten parts, salammoniac one part, prussiate of potash one part, iron filings free from oxide or rust about one-third of a part. The mixture should be reduced to powder in a mortar. Water is added until the mixture becomes a heavy mush. It is placed on a wood fire and stirred. A material of about the appearance of pumicestone is thus produced. It is then pulverized to fine dust and is ready for use. The flux is sprinkled over the metals to be welded when they are at the welding heat.

SOME SUGGESTIONS REGARDING LEGISLATION

WALTER S. SCHUTZ and Stanley W. Edwards are the attorneys for the Automobile Club of Hartford, and in a pamphlet recently prepared by them and submitted to the Committee on Roads, Bridges and Rivers of the General Assembly of Connecticut many excellent suggestions are contained. Introducing the subject, Mr. Schutz states:

"In considering the question of automobile legislation it should be borne in mind at the outset that up to the present time all laws on the subject have been to a great extent experimental. The State legislatures found themselves suddenly confronted by a new condition. A force destined to revolutionize traffic was abruptly let loose upon the highways; machines much more powerful than the early steam engines were created and entrusted to inexperienced hands for operation; something had to be done to protect the public and the frightened horse from the 'gasoline dragon.' Police regulations, more or less elaborate, were hastily enacted to fit conditions then most imperfectly understood. Just as the science of the motor car has developed, so we have every reason to believe will the legislation upon the subject become more scientific and better adapted to the needs of the public." Following are extracts of paramount importance:

"Are Not the Roads Made for Use?"

Is it not better economy to build our roads and keep them in repair to accommodate the new conditions rather than close our highways to the march of progress because a few of the property owners along these highways object to the dust and smell? If the roads are properly built and maintained at the expense of the whole State the dust nuisance can be reduced to a minimum, and the burden of repairing the roads would be taken from the towns that cannot afford to maintain them.

The motorist frankly admits that his machine wears out the roads, and he is ready and willing to pay his fair proportion of the cost of maintenance, provided the fact is not lost sight of that the lumber team and coal cart also wear them out.

Points to Be Covered by Automobile Legislation.

The principal points which recent automobile legislation is designed to cover are: (a) Proper identification; (b) control of operators by a revocable license; (c) speed regulations which shall not depend upon traps for their enforcement; and (d) revenue.

Identification by means of plates or markers is essential to the proper regulation of motor vehicles. Practically all the State laws provide for a registration of motor vehicles, or of the owners of such vehicles, and require that one or two plates, with the registration number and the initial letter of the State, be affixed to each motor vehicle. In Connecticut and in all of our neighboring States, except New York and New Jersey, these markers are furnished at cost price by the State official who issues the registration certificate, thus securing the great advantage of uniformity. In New York the State official furnishes a metal seal two inches in diameter bearing the registration number, and this seal must be conspicuously displayed upon the motor vehicle, in addition to the number, which must be displayed on the back of the vehicle, in figures not less than three inches in height. The provisions of our present law in regard to registration and the display of markers (Section 3 as amended by Laws of 1905, Chapter 282) are probably as good as those of any other State. No provision is made for identification at night, but the requirements of the Massachusetts and New York laws that the registration number be painted upon the front lamps are useless, as it is impossible to place numbers of sufficient size upon the lamps so that they can be deciphered when the vehicle is in motion. It might be well to prescribe that the markers shall be placed not less than fifteen inches nor more than thirty-six inches from the ground.

The Commissioner of Motor Vehicles of New Jersey in his most comprehensive report discusses at length this question of identification, and, while he admits that the present system is imperfect, he has no specific remedy to suggest. He gives as his opinion that a great reform may be accomplished by an interstate system of registration numbers. Should the bill for a national system of registration presented by the A. A. A. to the last Congress become law, most of the present difficulties would be removed.

Licensing of Operators.

Our present law makes no provision for the licensing of operators of motor vehicles, and in this respect differs from the laws of

most of our neighboring States. It would seem that the restricting of the operation of motor vehicles to those of suitable age, and who are able to demonstrate their ability to operate, would be the greatest possible protection to the public; and a license issue by a State official and subject to revocation or suspension if the licensee is guilty of reckless driving, or in any other way demonstrates his unfitness, would seem to be the most efficient check upon the misconduct of the automobilist. If a person operates a motor vehicle upon a public highway at a rate of speed greater than is reasonable and proper, having regard to the width, traffic, and use of the highway, impose a heavy fine and deprive him of his license, thus preventing him from operating a motor vehicle for, say, thirty days, and you would soon put a stop to all abuses.

In most States the applicant for a license to operate a motor vehicle must satisfy the official who issues the license that he is a competent and proper person to receive the same. In a few States, notably New Jersey, a more or less rigid personal examination is required, but the New Jersey Commissioner in his report advises against it. In the majority of States one desiring to operate a motor vehicle for hire must secure a special license renewable each year. Under the present New York law only chauffeurs are required to secure licenses, and no examination is prescribed. Connecticut should follow the example of her sister States in this regard and require every operator to obtain a license; this would give the State a direct control over all motorists, which could be exercised when necessary for the protection of the public, and it would also furnish an additional means of revenue.

Non-Residents.

Our present law (Section 8) provides that a non-resident, who has complied with the laws of any other State and displays the identification numbers required by such State, with the initial letter of the same, may use our highways for a period not exceeding fifteen days in any one year without complying with the provisions of our law. It may be said that if our own citizens are required to pay increased registration fees, or are to be specially taxed upon their automobiles, to pay for repairing the roads, non-residents, who do nearly, if not quite, as much damage to the roads, should be made to contribute. It would be a grave mistake for Connecticut to enact a law that would discourage residents of other States from coming here, for all our citizens, directly or indirectly, profit by their visits. Again, the drawing of State lines should be avoided as much as possible, and free passage from one State to the other is in all respects desirable. If our citizens enjoy the privilege of using the highways of New York, Massachusetts, and other sister States, without complying with the laws of those States, we can well afford to allow reciprocal privileges.

Speed Regulation and the Elimination of Traps.

It can scarcely be denied that the net result of enforcing the speed regulations of most of the automobile laws has been to swell the pockets of a few officials, without affording protection to the public or benefiting any one except these officials. The few traps set in different parts of our State have brought rich returns to a few constables, but public sentiment is opposed to this method of enforcing the statute, for it savors of highway robbery, and in nine cases out of ten it is the harmless, though technical, violator of the law who is caught and fined, while the reckless dare-devil soon locates the trap and laughingly escapes the punishment which he so richly merits. The only true test, looked at both from the standpoint of the public and of the automobilist, is whether the speed is at all times reasonable and proper, having regard to the width, traffic, and use of the highway. The only necessity for automobile regulation is to secure, as far as possible, the safety of the public by preventing reckless driving, and this can better be secured without a maximum speed limit than with it.

The disadvantages of maximum speed limits are very clearly pointed out by the Commissioner of Motor Vehicles of New Jersey in his report, and he unhesitatingly recommends their abolition. He cites a case, which came under the observation of his department, where a flagrant transgressor, who was caught by a mounted policeman, after a desperate race, and then only upon a threat of shooting, was acquitted before the magistrate because it was not proven that the vehicle was going faster than the maximum speed limit, although there was no question but what the speed was much greater than was compatible with public safety.

The claim will doubtless be made that the removal of the fixed rates of speed per hour would be an encouragement to the reckless motorist to drive his car at top speed regardless of the rights of others. A careful study of the subject has shown that the claim is not well founded; in fact, the converse of the proposition is found to be true. Maximum speed limits encourage the reckless

motorist to take every chance and to drive his car to the limit of its capacity, except where he has reason to believe that a trap has been set for him. Make reasonableness the foundation upon which speed is to be based, and the violator would never be safe from arrest and punishment, because any bystander would be competent to testify whether the motor vehicle was being operated recklessly or so as to endanger the safety of the public, instead of leaving the enforcement of the law to an official armed with an inaccurate stop-watch, and who is financially interested in the outcome of the prosecution.

It is a most significant fact that in no State where the arbitrary maximum speed limit has been abolished has there been any disposition to return to the old standard; in fact, the entire tendency of recent legislation is strongly in the direction of abolishing these arbitrary limits. The revocation of a few licenses to operate motor vehicles, with a heavy fine or imprisonment for reckless driving, will do more to cure the evil in Connecticut than a hundred traps working to their fullest capacity!

Revenues.

There is a general and very natural disposition to tax automobiles for the upkeep of the State highways. An equitable tax for this purpose certainly would not be objected to by automobile owners, but it is no easy matter to decide upon the basis for such taxation. One thing seems certain at the outset. If automobiles are to pay a State tax they should not be subject to local taxation. Our Supreme Court has many times reiterated the proposition that "it is and ought to be the general policy of the Legislature to avoid double taxation of the same property."

Some suggest that the taxation should be according to horsepower. The objections to this method are that ratings differ materially according to the maker or the place of manufacture, and that a heavy low-powered car may do more damage to the roads than a light high-powered one. The objection to taking weight as the basis is that the heavy electric vehicles and motor trucks, capable of only very low speed, do much less damage than the lighter but higher speed gasoline cars.

A plan which has been suggested, and which would accomplish the desired result without doing violence to established principles of taxation, is for each automobile to be taxed like other personal property, in the town where the owner thereof resides, and for the towns to remit to the State a fixed proportion of the taxes thus received to be used for highway purposes.

So far as we have been able to ascertain, no State has yet passed a law laying a special tax on motor vehicles. Several have materially increased the license fees for the purpose of revenue, and in Vermont, Rhode Island, New Jersey and Pennsylvania, as well as many of the other States, all fees and fines are applied by the State to the maintenance of State roads.

ONE YEAR IN WHICH TO REGAIN YOUR NUMBER.

ALBANY, N. Y., April 29.—That bill of Senator Wemple's to permit the Saratoga Lake Bridge Company to charge 25 cents toll for autos crossing the bridge, which is a rate twice as large as that charged any other vehicle and in direct contravention of the Whitney law enacted this year providing that the rates for motor vehicles over toll bridges and toll roads shall be uniform with those charged animal-drawn vehicles, got out of the Commerce and Navigation Committee in some peculiar way last week, but was recommitted on motion of Assemblyman Whitney, of Saratoga. It cannot now get out except through the Rules Committee, and it is not expected that the Rules Committee will take it up.

Senator Davis, of Buffalo, has introduced an amendment to Section 1, Subdivision 4 of the motor vehicle law, which reads as follows:

"If within one year from date when such seal shall have been returned, and the person to whom such seal was issued shall become the owner of a motor vehicle, and shall file in the office of the Secretary of State the statement required by Subdivision 1 of this section, and pay the fee required by this section, and, in such certificate, or at the time of the filing thereof, shall request the reissue to him of a seal bearing the same number as the seal surrendered, the Secretary of State shall issue to such a person a seal bearing the same number as that borne by the seal returned. After the expiration of one year such secretary shall issue to any persons applying therefor, and filing the proper statement, and paying the fee of \$2 as provided in Subdivision 1 of this section, bearing the number of any seal so returned and unissued."

AMERICAN CARS IN NEW BRUNSWICK.

United States Consul Hebbard Willrich, St. John, tells of the progress of automobiling in New Brunswick Province, the first car, an \$800 runabout, having been introduced in 1903. There were eighteen autos owned in the Province in 1905 and double that number in 1906. An association formed met with considerable success in securing funds for the improvement of the highways, the amount obtained being \$140,000 which expenditure has placed the Province roads in fairly good condition. Along the St. John river the scenery is unsurpassed. Some seventy cars are now owned in the Province, the great majority of which belong in the class ranging from \$2,000 to \$3,000. The remainder, with the exception of several French cars, are light touring cars and runabouts, ranging upwards from the buck-board. Fully 75 per cent. of the cars are of American manufacture, despite the import duty of 35 per cent.

Consul Willrich concludes: "Now is the time and opportunity for American manufacturers to cultivate and exploit this field, practically untouched. American machines are well introduced and have a big lead. They should retain it. The topography of this province demands machines that are both light and strong and good climbers, as the roads are up and down with seldom a long stretch of level. The scenery of this country almost everywhere is exceedingly attractive, hence offers much inducement to outdoor locomotion.

"As one of the best means of securing an increased sale of American machines, I would suggest the early establishment here of an American automobile agency having cars of different grades and prices in store, in charge of a competent mechanic able to make ordinary repairs. St. John, as the chief distributing point for the lower provinces, would be the proper place for the establishment also of a commodious and well-equipped garage, and I have no doubt that an investment here of that sort would prove a paying venture."

SOME GERMAN AUTOMOBILE STATISTICS.

United States Consul H. W. Harris, of Mannheim, advises that the *Deutsche Bergwerks Zeitung* recently published an interesting review of the German automobile industry, and especially recounting the progress made during the past six years, from which he compiles the following:

The review shows that the automobile, regarded for some years in Germany as a luxury only for the nobility and the very rich, is rapidly becoming popular and creating a demand for light vehicles of the runabout class. The many auto expositions which have been held, touring contests, and other events have greatly aided the industry as a whole. A more tolerant view on the part of legislators, the courts and police officials, and the public press has tended in the same direction. The value of the total product of the German automobile factories for the past five years is stated to have been as follows: In 1902, \$2,613,000; 1903, \$3,808,000; 1904, \$9,520,000; 1905, \$16,660,000, and 1906, \$23,800,000.

The value of automobile imports into Germany in 1906 is stated to have been about \$4,284,000, as against \$5,236,000 of exports. A larger proportion of this foreign trade has been with France than with any other single nation. For the six years, 1901 to 1906, inclusive, the imports of automobiles from France increased from \$214,000 to \$2,618,000, and the exports of machines thereto during the same period rose from \$119,000 to \$952,000. The total automobile exports from Germany to all countries have been from year to year somewhat larger than the total imports, the relative rate of increase being in favor of the export trade. It is stated that the German automobile industry, under like tariff conditions, will be able in the future to fairly compete with the same industry in other countries.

From the *Masonic Standard*: "Noble James McGee, of Mecca, has accepted an invitation to command a division in the Shrine parade at Los Angeles. The division chiefs, instead of bestriding barbed steeds, will mount wild and untamed automobiles."

WHAT HAPPENED ON THE ARLES-SALON ROAD

NOBODY really knows what actually did happen. We were bowling along in a light car, over the same famous bit of roadway on which the 200-horsepower Darracq first broke the record for the flying kilometer, when suddenly there was an abrupt stop of everything which had previously been in motion. The great pebbly plain of the Crau stretched north, east, south, and west in all its lonesomeness, with no one to give us a helping hand or to tow us into a Salon garage, a good twenty kilometers away. It was a discouraging prospect.

Everything was put out of business for the moment, the accumulateurs had turned over and the occupants of the front seat and the tonneau all but precipitated to the ground. Visions of a gripped piston, a broken cranksbaft and everything else to be thought of passed through the minds of all of us in the brief interval required to get over the shock and the surprise. It was but a moment of time before the *manivelle*, as the French neatly call the cranking-handle, was gently turned and went over with its accustomed ease—nothing wrong there. A good strong shove on the automobile showed that it rolled over the smooth road without indicating that anything was wrong with the transmission. With these facts well established and with a general lookover of the gasoline supply pipes, the wiring, and the thousand and one little intricacies that only the habituated chauffeur can diagnose with a glance of the eye, the current was switched on—the brakes hard on meanwhile—and a cautious effort made to put the motor *en marche*. The unexpected happened! Or, rather, nothing out of the ordinary happened; the thing went off as though it had only been stopped while we were taking a fifteen minute look around the landscape. This was one of the capricious moods of the automobile, moods which, if not frequent, are ever on the eve of being sprung on the unsuspecting chauffeur. "*Sont capricieuses comme les femmes*," said an old shepherd standing by, who with his flock of a couple of hundred *moutons à laine*, are almost the only residents of this great stony plain. And we were inclined to agree with him. This particular automobile, it is only fair to say, ran another three thousand kilometers without the least involuntary stop. It had been done nobly, and was to be forgiven.

A Stop Which Led to Old World Scenes.

But for this involuntary stop in the Crau it would have slipped our minds entirely that we were on classic if not hallowed ground, for we were bound Italy-wards and had never a thought but to make the *vitesse* and get over the frontier at Vintimille as soon as possible. As it was, someone of the party suggested that we spend the night at St. Rémy, just over the crest of the purple Alpilles to the right, the last spur of the French Alps, as they bury their fore foot in the shallow plain of the Bouches-du-Rhône. It was the artist who suggested this, for she had memories of a long summer spent in the household of an estimable bourgeois of St. Rémy and had not forgotten either the classic excursion to Les Baux for its shepherds' midnight fête, or to the home of the poet Mistral, and the thousand and one marvels of this all-but-unknown tract of country, as weirdly strange and full of character as any similar area to be found. It is a district in which the tourist *en auto* might spend all his available leisure to advantage.

Where Hemérys Break Records and Tourists Speed.

By all means the thing to do was to spend the night at St. Rémy; the chance might not come our way again, involving so

little forethought on our part. We turned off the great national thoroughfare, the Arles-Salon road, with the memory of the most superlative bit of roadway in all the world burned well into our brains. Almost the whole distance from Arles to Salon, something like forty kilometers, is as straight as an arrow and as flat as the proverbial billiard table. In addition its surface is as smooth and hard as if it were of marble and about as dazzlingly white as that variety of which tombstones are made. It is, indeed, the finest bit of natural roadway in all the world, and we were glad indeed, when we came to think of it, that we had not scorched over it at "80" or a "100" an hour (kilometers, not miles) as is mostly done by passing automobilists. Les Baux called us, however, and the thought of the good things to eat that night and the comfortable quarters to be had *chez Teston*, at the Grand Hotel de Provence, did the rest, and Italy for the nonce was far from our minds.

Les Baux, reached only by road from Arles or St. Rémy (here's where the automobilist has the advantage of the traveler by rail), is one of the reminiscent wonders of the past that tourists to the Riviera should by no means give the go-by, as they mostly do. For that matter, they should not neglect Arles and Avignon. They are something more than dining and sleeping places, though not many seem to realize this until they get on the spot. There is so much history connected with both these cities of celebrated art that the wonder is that they have not become really popular shrines before now; Arles with its Roman arena, almost as great as the Colosseum, and Avignon with its Palais des Papes are certainly suggestive of much in the way of attractions that the most callous scorcher will hardly want to pass by when he comes to think of them.

Mem.—Don't pass by Arles, Avignon, St. Rémy or Les Baux, or you will miss much of what you come abroad for.

In the Home-land of the Haughty Seigneur.

The distances between these charming Provençal towns are astonishingly small and a week's tour among them, between Avignon and Marseilles and westward to Nimes, will give one at least a score of surprising delights in the way of quaint sights and scenes, and good eating and drinking at modest little inns, which will be a revelation to those who have hitherto been frequenters only of the resorts.

Les Baux is a mere weatherworn souvenir of a city whose glory has long ago passed into foggy oblivion. Once its seigneurs held sway over sixty Provençal towns and cities whose inhabitants didn't dare to call their souls their own but went and laid them at the feet of their feudal lords, the seigneurs of mouldering old Les Baux. Now, though

MOUNTAIN ROAD TO LES BAUX.

a ruin, Les Baux is a sight so wonderful that it is only comparable to Pompeii. It is virtually a dead, buried relic of a once proud and wealthy metropolis, though, unlike Pompeii, it sits imposingly on a rocky peak, with the great plains of the Crau and the Camargue stretching away seaward, and the rich, alluvial prairies (where at Chateaurnaud is the largest market for primeurs, or early vegetables, in all France) to the north, with now and then the glint of the gold dome of the cathedral at Avignon and the sky-line of the Palace of the Popes showing through the sunlight like a veritable mirage.

It's a long, hard climb up to Les Baux from whichever side one tackles the mountain road. It is six or eight kilometers up a regular mountain side, with rocky gorges, picturesque defiles and all the accessories which go to make up a picture by Gustav Doré. As one swings around the last hair-pin turn and dodges the last flock of sheep and their worrying dog he comes at once abruptly on the little Place of Les Baux, where now two hundred inhabitants pass to and fro, replacing the sixteen thousand of another day.

There is nothing quite so weird and strange as this in the center of a thickly-populated region round about in all France. There is a hotel of sorts—a very poor sort, and there is an apology for an "auto garage," as you learn from a great white banner swung to the breeze in front of the Hotel Monte Carlo. It's nothing much, but you may stable your machine along with the omnibus which makes the round twice a day from Arles.

Charms of a City of the Misty Past.

The old defences, the fortress-chateau, and the city walls are defined as well as one might expect of anything which has had to stand up for centuries against the icy blasts of that terrible "norther," the mistral. For the most part the town is a ruin and a wilderness, but here, there and everywhere a turn of the shovel or even a sharp glance of the eye will point out buried evidences of the splendor that once existed.

Once proud and revered seigneurs and fair ladies stalked through the grim halls of the chateau where an occasional antiquarian toddles to-day, but for the most part it is the abode of owls and other nocturnal rambles which must give the shudders to anyone venturesome enough to go up there in the night.

FROM CLOISTER TO SHEEPFOLD, ST. REMY, IN PROVENCE.

The chief evidences of existing splendor are found only in the "Temple," a sixteenth century religious edifice, which is a luxurious ruin if nothing more. "Post Tenebra Lux" may be read over its portal, but one will have to build up its past for himself, as the religious functions of Les Baux to-day, such as the shepherds' midnight fête at Noël and the Fête de Vincent in January are more strangely weird and fantastic than they are splendid and magnificent.

From all parts of the surrounding country, and often from the Alpine regions, come the shepherds to Les Baux for the midnight mass at the Fête de Noël, that they may pray and be prayed for; that they may be deserving of a growing prosperity, and that their flocks may increase in number, and, above all, that the price of wool will continue to be as good as it has been—and better. Very practical this, but no one who has ever seen the weird midnight processionings with lighted candles and lanterns and great rows of men, women and children climbing up to the hill-top town of Les Baux from the lower plains at the base will doubt the sincerity of it all. Prayers need not be made in city churches to be effective, indeed the other kind seem to be the most efficacious.

Where Mistral Found His Inspiration.

The round of the sights of Les Baux, which are many, will occupy one hour or three as you choose, and then there is the "Trou di Fado," or the "Grotte des Fées" or the "Fairy's Well," or whatever you may choose to call it.

You get the pure Provençal tongue hereabouts almost to the exclusion of the French, and if your demand for the road leading to the "Grotte des Fées" is not productive of anything except a jabber, you may know that you have struck some old-school Provençal who has never been taught French and hasn't chosen to learn it for himself.

There is a two hundred and eighty meter drop down into St. Rémy on the north side of the Alpilles, where all that is lacking at Les Baux awaits one and his automobile.

On the occasion of which we write we made the nine kilometer descent just as dusk had fallen. There is little or no twilight here and night comes with a rush. Our lanterns and our phares were alight and the effect was as strange and spectacular as a stage-setting. Nothing surprising happened and we made all the lacets, or hair-pins, safely, taking corners slowly, as indeed one must, and just escaping a flock of sheep by the thickness of the paint on our mud-guards. Every rock and tree stood out in bold relief, and though the hour was not yet six it was as dark as a pocket, and still as if it were the desert.

We arrived safely before the door of St. Rémy's excellent hotel just as the soup was being served and, after the necessary "wash and a brush-up," did full justice to Teston's Provençal cooking and slept the sleep of the just in a great four-posted bed in an appallingly spacious apartment overlooking "les antiquités," a brace of Roman relics—a great mausoleum-like tomb and a triumphal arch—whose history is lost in the night of time.

St. Rémy is *toujours une ville morte*, say the inhabitants, but for all that it is as delightful and sleepy an old-world town as one will see on a long round of French travel. It would be an ideal place to while away a month, or a year for that matter, and it would doubtless wear well.

(To be concluded.)

A STREET IN LES BAUX.

HAPPENINGS IN THE BUSY LAND OF CLUBDOM

Windy City Clubmen Prepare for Season's Campaign.

CHICAGO, April 30.—Preparations for the entertainment of the Glidden tourists when they reach this city on July 13 were inaugurated by the action of the Chicago Automobile Club in instructing its racing committee to arrange a short program of events for that day, providing a suitable track can be obtained for the purpose. Chairman C. E. Gregory has in mind the old Harlem race course for the purpose, providing the expense of putting the same into shape for racing is not too great.

Plans for the observance of Orphans' Day—June 12—were formulated by the Chicago Automobile Club at the last directors' meeting, and the following committee was appointed to take charge: Joseph F. Gunther, chairman; Frank H. Pietsch and C. E. Gregory. Progress on the construction of the club's new house on Plymouth court was reported at the meeting, and there is every evidence that it will be ready by May 30.

The Bay State Meet to Have Two Long Races.

BOSTON, April 29.—Entry blanks are being sent out by the racing committee of the Bay State Automobile Association for the fourth annual race meeting to be held on the Readville track on Memorial Day, May 30. The programme is quite different from those of previous meetings in that there are to be only two events: races at 100 and 50 miles respectively. The 100-mile race is open to all stock gasoline touring cars. Mufflers, mud guards and lamps may be removed, otherwise the cars must be as per maker's catalogue. Each car must carry one passenger in addition to the driver. The fifty-mile race is open to all stock gasoline runabouts and the conditions are the same as for the touring car race. Silver prizes are to be given to the first three to finish the touring car race and the first two in the runabout race. The committee is well pleased with the response among owners of cars and expects to have as many as twelve machines

COMMITTEE OF THE HARRISBURG MOTOR CLUB THAT SELECTED THE COURSE FOR THE ENDURANCE RUN OF MAY 6-7.

First White steamer on left—R. H. Johnston, of the New York Motor Club, who will distribute the confetti on the run; second White steamer—R. C. Haldeman, chairman of the committee; W. R. Douglass, I. W. Dill, and C. C. Crispen; Stanley car—George G. McFarland, Vice-President O. C. Robinson, L. A. Fannel, and Andrew Redmond; Pullman car—E. G. Irwin, R. L. Morton, Charles Cumler, and J. Aldrich.

The contests committee of the Chicago Motor Club, which will have charge of the second annual Elgin-Aurora reliability run, the Algonquin hill-climb, and the Cedar Lake economy contest, and which will be run jointly with the Chicago Automobile Trade Association, has been appointed and is constituted as follows: Charles P. Root, chairman; B. C. Hamilton, J. V. Lawrence, B. C. Buxton, F. W. Cornish, H. P. Branstetter, and J. C. Zimmerman.

A. C. A. Jamestown Tour in October.

NEW YORK, April 29.—The Runs and Tours Committee of the Automobile Club of America has decided to have its trip to the Jamestown Exposition for club members take place the first week in October instead of in June. The present plan is to tour from New York to Washington, and then take boat to Norfolk, leaving the cars at the Capital. Returning there, the route home will be more or less diversified, the exact details to be decided upon by A. L. Westgard, secretary of the club's Bureau of Tours, who will go over the route early in the summer.

in each of the races. The entries close with L. R. Speare, chairman of the racing committee, at the clubhouse, 282 Dartmouth street, Boston, May 23.

President George Refuses Re-election in Detroit.

DETROIT, April 29.—At the annual meeting of the Automobile Club of Detroit, Edwin S. George was pressed to accept a fourth term as president of the club, but declined and was succeeded by Harry Skillman, whose work as secretary during Mr. George's administration was strongly contributory to the excellent results attained. When Mr. George was first elected president of the club three years ago, it was a small organization with few members and \$600 in debts. Since then it has grown tremendously, has its own clubhouse, no debts and a snug balance in the bank, as the result of his efforts in building it up. The other officers elected were: Dexter M. Ferry, Jr., vice-president, and Garvin Denby, secretary. E. S. George was reelected to the board of directors, and C. A. Ducharme and Louis Case, whose terms had expired, were succeeded by Garvin Denby and Walter Brooks.

Such a success was made of the century run last year that the tours and contest committee decided to make it a fixture, while another proposed annual fixture is the motor-boat race off the Pine Lake house of the club. The good roads committee succeeded in building a two-mile gravel cut-off, which reduced the distance to the country house six miles, and the farmers in that district have been so pleased with it that they have agreed to contribute to the building of an additional two miles. The gain in the club's income in one year has been \$2,000, and it is intended to make a substantial outlay in enlarging the Pine Lake house this summer.

New Jersey Club Election Promises Warm Contest.

NEWARK, N. J., April 30.—Since the regular list of nominations for officers for the coming year made public by the New Jersey Automobile and Motor Club, of Newark, an opposition ticket has been placed in the field. The regular nominations were: Angus Sinclair, president; L. T. Wiss, vice-president; James C. Coleman, treasurer, and H. A. Bonnell, secretary, while W. C. Shanley is slated for president on the opposition ticket; F. R. Pratt, vice-president; W. I. Fisk, treasurer, and Leslie P. Ward, secretary. An opposition ticket was placed in the field last year, but was withdrawn prior to election. It does not seem probable that this will again be the case, so that the election on next Monday night promises to be closely contested. The opposition members of the board of trustees nominated are Charles W. Baker, E. Z. Seitz and Dr. F. B. Meeker.

Horace A. Bonnell, chairman of the club's endurance run committee, announces that twelve entries have already been made for the three-day event to be held on May 30-June 1, and has verbal assurances that this number will be increased to fully thirty in all before the end of the month.

First Banquet of a New Greater New York Club.

NEW YORK CITY, May 1.—The City and Country Motor Club of Greater New York, with a clubhouse at 306 West 109th street, held its first annual banquet Wednesday night. The dinner was tendered to the hundred founder members and the press. It marked the formal opening of the club.

There is at the present time a waiting list of about 200, whose names will be acted upon at the next meeting of the membership committee. A very novel feature of the club is the fact that ladies are eligible to membership. They cannot, however, hold any office, excepting on special sub-committees.

Final arrangements have been made and a lease for a term of years secured for the Lake Mahopac Inn. There are garage accommodations for at least fifteen cars, and there will be kept on hand stocks of spare parts, tires, oils, greases and gasoline. Sign posts will be erected by the club between New York City and Lake Mahopac for the convenience of members.

Michiganders at Grand Rapids Elect New Officers.

GRAND RAPIDS, MICH., April 29.—At the fifth annual meeting of the Grand Rapids Automobile Club the following officers were elected: President, A. A. Barber; vice-president, Alvah W. Brown; secretary, D. Emmett Welsh; treasurer, J. R. Jackson; board of governors, Fred M. Rowe, William Wurzburg, Dr. Warnshuis and the above named officers. One of the most important features of the meeting was the appointment of a committee whose duty it will be to further the cause of good roads in this vicinity. The committee consists of George W. Hart, C. C. Filberts, C. J. Bronson, W. B. Vandecar and Robert Erwin. Thirty-five new members were added at the meeting.

Adirondack Autoists Organize New Club at Sandy Hill.

SANDY HILL, N. Y., April 29.—The Adirondack Automobile Club has been organized at this place with twenty charter members, and the following board of officers: President, W. A. Hup-

puch; first vice-president, W. R. Durkee; second vice-president, M. C. Allen; secretary and treasurer, W. J. Gallagher. The club has affiliated with the New York State Automobile Association and the American Automobile Association.

Energetic efforts will be made by the club to improve the roads in this immediate vicinity. The Lake George-Glens Falls State road is in many places very dangerous to automobilists on account of the numerous sharp turns, and as it is one of the main thoroughfares from Saratoga to Lake George during the summer season, it is thronged with high power touring cars most of the time. The club is having placed at danger points on the road signs cautioning tourists to drive slow.

Indiana Automobile Club Elects Officers.

INDIANAPOLIS, IND., April 27.—What answered as the annual meeting of the Indiana Automobile Club was held to-night at the Dennison Hotel. These officers were elected: President, Louis H. Levey; vice-president, S. A. McClellan; secretary, H. H. Rice.

H. O. Smith made an address as to the necessity of organization, and R. J. Eads spoke in similar vein, dwelling particularly upon the benefits of A. A. A. membership. Reference was also made to the excellent work of Edgar Apperson before the Indiana Legislature, he demonstrating to some of its members the errors in bills which they were about to pass and the effect upon the growing industry in Indiana.

Forty new members were admitted, and it was stated that the latch string of the new clubrooms in the Dennison Hotel would always be open to A. A. A. members.

Bison Autoists Object to a City License.

BUFFALO, N. Y., April 29.—Members of the Automobile Club of Buffalo have been requested by special notice from Secretary D. H. Lewis not to pay the annual license of \$5 for the operation of automobiles in the public thoroughfares, as demanded in an ordinance recently adopted by the Common Council. Former Justice D. J. Kenefick has been retained in case the law is put to a test, which is desired by the Automobile Club. Mr. Kenefick says it is his opinion the ordinance is invalid. In all there are at least 3,000 automobiles in Buffalo. Mayor Adam this afternoon sent a communication to the Common Council dealing with this subject, in which he expresses regret at the action of the club.

Long Island A. C. Decides to Return to A. A. A.

BROOKLYN, N. Y., April 29.—At its recent meeting the Long Island Automobile Club unanimously decided to rejoin the New York State Automobile Association of the A. A. A. This action was taken after a special committee, consisting of Charles Jerome Edwards, Alfred Wilmarth and Dr. C. D. Parker, had reported the results of a conference with A. A. A. officials. The renewed activity of the present A. A. A. administration and the new distribution of the annual dues, whereby three-quarters goes to the State body and only one-quarter is retained by the national organization, had much influence in taking the club back into the A. A. A. fold. Its present membership is over 400.

Capital City Autoists Improving their County House.

WASHINGTON, D. C., April 29.—With the opening of the spring season the country clubhouse of the Automobile Club of Washington on the Brightwood Road is becoming a popular place of resort. The house committee is taking an active interest in improving the facilities of the clubhouse, as well as in beautifying the grounds surrounding it. With a view to increasing the membership a committee is now making arrangements to put into attractive shape the desirability of automobilists joining the organization. The new officers of the club are working hard to make the club a success in every way.

GREAT GROWTH OF THE A. A. A.

Fifteen State associations of the American Automobile Association are now in active operation. These eight were added to the roll at the Monday meeting of the Executive Committee, held at 527 Fifth avenue, New York City: Pennsylvania, Indiana, Maryland, Michigan, Wisconsin, Missouri, Colorado and Rhode Island. The Automobile Club of Louisville, Ky., and the Automobile Club of Rutland, Vt., were also admitted, and very shortly both clubs will have become parts of State associations now in process of formation. These additions brought the grand total of the national organization to about 16,000, with several other State bodies probabilities of the near future.

President W. H. Hotchkiss presided at the session, which was also attended by Lewis R. Speare, W. K. Vanderbilt, Jr., Jefferson DeMont Thompson, G. E. Farrington, A. G. Batchelder, Secretary F. H. Elliott, and Chairmen Charles T. Terry, of the Legislative Board, and Frank B. Hower, of the Touring Board.

Chairman Hower, of the Touring Board, reported extensively concerning the annual A. A. A. tour, to take place in July. His recommendation was that a separate class for runabouts should be included in the tour. The Executive Committee concurred and accepted a cup for the runabout division offered by Mr. Hower. The rules governing the Hower cup will be exactly the same as those for the Glidden trophy, for which touring cars only will compete.

Chairman Terry, of the Legislative Board, filed a decidedly interesting report, referring to favorable legislation obtained in various States, and also made known that not a single serious objection had been expressed to any of the provisions of the Federal Motor Vehicle bill which the A. A. A. had introduced in Congress before the close of the recent session. The proposed statute will go before the Judiciary Committee of the House of Representatives upon the reassembling of Congress, with indications of a favorable report.

Chairman Hooper, of the Good Roads Board, reported that arrangements are being perfected for a convention of officers of all associations throughout the entire country interested in the improvement of the highways. According to Mr. Hooper, the era of good roads building will soon be in full sway, many States considering the subject favorably at the present time.

Chairman Thompson, of the Racing Board, announced a session of the Executive Committee of the Racing Board, to be held May 15 at the new offices of the association, 437 Fifth avenue. The appointment of this Executive Committee was ratified, and to it was referred the entire management of the Vanderbilt Cup race and similar events run under A. A. A. auspices. This committee, in addition to Chairman Thompson, contains W. K. Vanderbilt, Jr., E. Russell Thomas, Dave H. Morris, A. R. Partridge, A. G. Batchelder, Frank G. Webb, S. M. Butler, R. Lincoln Lippitt, George L. Weiss and Ira M. Cobe.

A letter received from H. O. Smith, of Indianapolis, representing a number of well-known makers interested in the promotion of a stock touring car race, stated that suggestions for such an event would be forwarded to Chairman Thompson in time for next Racing Board meeting.

Changes in the Board of Directors included the substitution of W. F. Fuller, president of the Automobile Club of Hartford, Conn., in place of J. Howard Morse, who resigns because of an extended trip abroad, and Paul C. Wolff, secretary of the Pennsylvania Motor Federation, in place of Philip S. Flinn, who requested the change, stating that his memberships on the Racing and Touring Boards occupied all of his spare time.

MALDEN CLUB PURCHASES A HOME.

The Malden Automobile Club, of Malden, Mass., has purchased the Southmayd property at the corner of Florence and Clement streets, this city, which includes a large frame residence of nineteen rooms and about 12,000 square feet of land. About \$5,000 will be immediately expended by the club in alterations and the erection of a modern garage on the property.

WIDER SCOPE OF NEW BLUE BOOK.

Instead of comparing bulk for bulk, a better idea of the growth of "The Automobile Official A. A. A. Blue Book" can be obtained by comparing one portion in the 1906 edition with the corresponding matter in the new edition. Take as an example the index matter dealing with Erie, Pa. Last year this occupied 8 1-2 inches. In the new edition 26 inches of space are occupied for the same subject. Instead of the old map, which, in order to economize space and time had a small city map incorporated with it, there is one large city map, showing all routes for entering and leaving the city. In the old book it was only possible to give three routes, all fragmentary, whereas in the 1907 edition there are five complete routes and two alternates, making seven in all. The tourist is given a comprehensive idea of the city of Erie by a new map drawn to the proper meridian point, with captions very much extended. Instead of trying to squeeze the route map in a corner of the city map this material has been made into route maps that extend complete and independent to various centers, while the small map used in the way referred to last year has been enlarged and made to serve the purpose of showing the surrounding country on a larger scale.

This is an example of the reconstruction process that has been carried out in the book. Every section that could be enlarged and improved has been attended to, so that the progress has been not merely theoretical but eminently practical. To the New England section of the Blue Book will shortly be added Sections 1 and 3, dealing respectively with New York State and the West, and with New Jersey, Pennsylvania, the South, and the West. The three volumes are published by the Class Journal Company, publishers of THE AUTOMOBILE, Flatiron Building, New York City. The price is \$2.50 per volume.

FAVORABLE FOR THOSE TOURING CANADA.

SEATTLE, WASH., April 26.—The United States Collector of Customs at Port Townsend has issued a new order concerning automobiles that are taken to Canada on tours. The new order says that to facilitate tourist travel to and from Canada automobiles may be taken into Canada, and upon reimportation to this district within thirty days will be allowed to pass the customs port without making entry.

The owner of a machine should file with the Deputy Collector at the port of exit a description in duplicates of the automobile with the maker's name and number, its retail value and the place the car will return through. A copy of the statement, duly certified by the customs officer, will be given to the tourist to be delivered at the port of re-entry. The order also says that all automobiles returning or departing by vessel should be carried as baggage, and not entered on the ship's manifest.

THE SHORT AUTO ROUTE TO THE JERSEY SHORE.

SOUTH AMBOY, N. J., April 29.—By granting the Jersey Central Traction Company the right to lay tracks on the draw of the new Perth Amboy-South Amboy bridge, last Wednesday, the Middlesex Board of Freeholders practically completed their work of establishing a short automobile as well as trolley route to the Jersey shore. The trolley company will light the bridge at night with 16-candlepower incandescents, placed 100 feet apart, and will furnish power to turn the draw. The company pays the county \$5,000 cash for a twenty-year franchise. The work of putting steel spans in the bridge to replace part of the wooden structure has been proceeding rather slowly, and it will probably be late in the summer before the bridge is thrown open to traffic. The Freeholders are having a new macadam road laid from South Amboy to Keyport. This, with the bridge and the "Hole in the Wall" repairs, will complete the new shore route.

Germany proposes to form a standing auto division in its regular army. It is said to be a pet plan of the emperor.

Passing of the Horse as Cab and Bus Power. From the time that the first automobile made its appearance on the scene the passing of the horse has been freely predicted. So freely, indeed, that it probably must be a laughing matter to the horse himself by this time, for the prevailing prices of horseflesh have seldom been higher than during the period that has marked the reign of the automobile. According to some of the prophecies, the genus was to vanish from the face of the earth completely, but after the better part of a decade its hold on existence does not appear to have been seriously shaken. The truth of the matter is that the effect of the automobile on horse traffic only began to be visible within the past year or two in the gradual appearance of more and more commercial motor vehicles. But at best the inroads made by the latter have been sporadic and not of great moment even in the aggregate.

It has remained for cab and bus-using communities such as London and Paris to sound the death knell of the horse in the field in which he has been most numerous. London boasts of between 7,000 and 8,000 buses, and in less than two years at least 1,000 or more have been transformed into mechanical vehicles, which alone means that 6,000 horses have been taken off the streets. In Paris there are 800, of which 100 are now mechanical—a matter of 900 horses less, as Paris buses are drawn by three and three teams are used in relays. Of the 10,000 cabs that Paris can boast, 2,000 are already motor-driven, and both London and New York are seriously awakening to the motor cab. At the rate at which the two foreign cities are at present progressing in this direction, scarcely half a decade will pass before the

horse-drawn public service vehicle will be a thing of the past. In those two cities alone this means the emancipation of some 60,000 horses—probably more—so that it would seem that at least some of the predictions regarding the passing of the horse have not long to wait for their complete fulfillment.

Coming of the Poor Man's Automobile. Ever since the automobile first outgrew its original status of an uncertain plaything only to be toyed with by the ultra wealthy there has been a constantly increasing contingent who have confidently looked forward to the coming of the "poor man's automobile." Just what financial limitations may be considered as sufficiently defining the term in a country where the per capita wealth is so high, is a query not to be answered off-hand, but current opinion has it that \$500 or thereabouts is a figure at which every man can afford to have his own car, some estimators naturally dropping considerably below this while others consider that an additional hundred or two would not bring it beyond the category bounded by the title. Opinion likewise differs as to just what should constitute the chief features of such a car, but views differ as widely in this as in the field of the larger cars, so that it would be difficult to reconcile them, though it may be added that air-cooling and the two-cycle motor predominate very largely, for the popular automobile must be a simple machine.

At first sight it appears ridiculous to broach the subject of the poor man's automobile as being any nearer fulfillment at the present moment than it ever has been. Well-known cars that sold for \$3,000 but three years ago have gone up fully 40 per cent. and far more of them are sold now than was the case at the lower figure; several that started at \$2,500 only two years ago have risen to \$2,800 and \$3,000, and the same tendency has been noticeable throughout regardless of the class to which the car belongs. Better materials and better construction mean better cars, but they cost more; the automobiling public has demonstrated its willingness to meet the makers on the price question and the latter have responded generously in the matter of improvements. On the other hand, there has been evolved a totally different style of machine during the same period, variously denominated the "buggyabout," the "farmers' automobile," and the like. With their simple construction readily understood by the average man and easily repaired by the wayside blacksmith, these cars would certainly seem to represent the entering wedge that means the coming of the poor man's automobile.

Regulation Needed in One Particular. But a year or two ago, the extent to which the municipal governments of such foreign cities as London and Paris went to in restricting the automobilist doubtless appeared to be the height of absurdity to the average American autoist. Take, for instance, ordinances against the production of an undue amount of smoke; to an American such a regulation savored of nothing short of absolute tyranny. To haul a man up in a police court and either cut his ride short altogether by requiring the deposit of his machine, or mulcting him roundly for a fractional violation of an arbitrary speed limit was certainly bad enough, but to pile it on by making him pay for creating a bit of smoke was beyond all reasonable conception of the needs of the case.

And so it seemed then. Such ordinances are rigidly enforced abroad in the two cities named, the duty devolving upon the bicycle police in Paris. At a conservative estimate New York City can now boast of anywhere from 10,000 to 17,000 automobiles, a large number of which are in constant daily use, and any autoist who has much occasion to pass along streets frequented by cars can appreciate the need of an anti-smoke ordinance. It is not unusual to see a cross-walk lost to view by reason of a standing car belching forth volumes of ill-smelling vapor. New York's chauffeurs are so careless in this respect that many would be up several times a day were the French rule applied.

DETRIMENTAL GOOD ROADS LEGISLATION.

ALBANY, N. Y., April 29.—It would appear that there might be some interference with the annual appropriation for good roads building, which information will be disappointing news to all road users of the Empire State. Commenting upon the situation, Oliver A. Quayle, president of the New York State Automobile Association, to-day said:

"From present indications, legislation effecting the matter of good roads construction in the State of New York will be considerable of a disappointment to the users of automobiles. It has been supposed that the policy of this State with reference to the matter of highway construction had long since been definitely fixed, and that with greater experience would come more effective methods. A sort of self-appointed committee of three—consisting of A. R. Shattuck, a prominent automobilist; W. Pierrepont White, of Utica, a friend of the farmer and a good roads agitator, with Frank D. Lyons, of Binghamton, a politician and an ex-employee of the State Engineer's office—has been most active before the Legislature this year in urging the appointment of a commission which it was intended would supervise the construction and maintenance of the State highways. This agitation has worked itself out, not as originally intended, but in the form of two bills now pending before the Legislature, appropriating funds for good roads construction. The appropriation of former years is materially reduced or entirely done away with. The passage of these bills in their present form would not only arrest further progress in good roads building, but would, in some instances, necessitate the abandoning of work already begun."

STATE ENGINEER SKENE.

State Engineer Frederick Skene has had considerable experience in good roads construction, having given special attention to the subject of oiled roads, his experiments having developed results sufficient to justify utilizing them in practice. Mr. Skene is a resident of Astoria, L. I., was educated in the public schools of Long Island City, received the degree of B. S. at New York University in 1896, and the degree of C. E. after one year of post-graduate course in 1897. Appointed to a place in the County Engineer's office of Queens County in 1897, he remained until January, 1898; then was appointed an assistant engineer in New York City after the consolidation, and has been in charge of the engineering office of the Bureau of Highways, Borough of Queens, since 1899. Mr. Skene was a member of the Board of Governors of the Municipal Engineers' Society in the first year of its existence, and is still a member of the society. The impression is general that he is exceedingly well qualified for the office which he now holds, and there is a pronounced sentiment that he should not be hampered in carrying out the work of improving the roads of the State, begun last year, and now in danger of interference from a somewhat unexpected source.

PERCY OWEN AGAIN HEADS TRADE ASSOCIATION.

At the annual meeting of the New York Automobile Trade Association, which took place last Friday night, Percy Owen was unanimously re-elected president for another year, the other officers being Frank Eveland, first vice-president; E. S. Partridge, second vice-president; W. P. Kennedy, treasurer; E. V. Stratton, secretary and general manager, and Carl H. Page, John F. Plummer, C. Andrade, Jr., Frank Eveland, C. R. Mabley, Peter Fogarty and W. H. Haradon comprising the board of governors. The association expects to be established in its new headquarters in the Motor Mart, at Sixty-second street and Broadway, within a short time and will then begin an active campaign which will be managed by Mr. Stratton.

AMERICAN IMPORTERS' SOCIETY ORGANIZED.

An American Automobile Importers' Society is a reality, and an importers' automobile show a possibility. Fourteen prominent importers have united to form the nucleus of the association, of which G. H. Rheims is temporary secretary, and an effort is being made to enlist twenty or thirty more automobile importers in the cause.

"We have not united to fight the Licensed Association," said Percy Owen, of Bianchi fame, to THE AUTOMOBILE representative. "Our aims are to unite all importers, irrespective of their connection or otherwise with the Seldenites, in an association which will have for its main object the promotion of the interests of importers of foreign machines. Most of the daily papers and a section of the technical press has made capital of the statement that we are to fight the Licensed body; such is absolutely incorrect."

An interview with G. H. Rheims, of the C. G. V. firm, brought forth the statement that the new society had been called into existence primarily because of the changed dates for the New York independent and licensed shows. No European models will be available for show purposes until immediately after the Paris Salon, which closes its doors December 1. New York importers will thus be effectively debarred from exhibiting their 1908 wares at the coming shows as if Maxim guns were across their path.

"We shall be obliged to hold a separate show," said Mr. Rheims, "some time after the two regular New York exhibits. Particulars are not yet available, but with such firms as Panhard, Renault, Westinghouse, Mercedes, Delaunay-Belleville, Mors, Bianchi and C. G. V., as well as the probability of the remainder of the importers joining in, there is every ground to believe that we shall have a successful show. I do not believe, either, that the holding of our exhibit after the regular shows will affect our sales."

"As a compensation for being debarred from the Madison Square show," said Secretary Butler, of the A. C. A., "the A. L. A. M. has granted the use of the Madison Square Garden from December 28 to January 4 for the holding of a show of licensed and unlicensed importers."

It appears that the conditions on which the use of the Garden is granted is that the exhibitors in the Importers' Show shall not take part in any other automobile exhibition in New York.

In reply to a query on this point, Mr. Butler declared that he did not think any of the firms would agree to such a restriction. "The date, too," he continued, "is far from being satisfactory, and it is not at all certain that the Importers' Society will accept the Garden under such conditions."

AMERICAN CAR FOR HERKOMER TOUR.

The Herkomer list has closed with a total of 170 entries, ten more than last year. America will be represented by a Rambler car to be driven by Carl Hirsch, a publisher and sportsman of Constad, Baden, Germany. Mr. Hirsch was in Chicago recently and made arrangement for the shipment of a 40-horsepower, 4-cylinder touring car from the Kenosha factory of the Thomas B. Jeffery Company. Late entries are received on payment of double fees until May 15. England only sends four cars into the fray this season, instead of the stately list last year; two are Napiers of six cylinders, one to be driven by Miss Leavitt, the other by Cecil Edge; the third car is Robertson Grant's Argyll, and the fourth Director Loeser's Belsize. France is represented by a Renault, a Mercedes, a Berliet and a De Dietrich; Italy only by an Isotta Fraschini, although entries comprising cars of all makes have been received from Germany itself. The Dutch entries are somewhat amusing, two Mercedes and an Adler. Both Herr Ladenburg and Dr. Stoess, winners of the contest last year, are also down to participate, and at the present writing they complete the list. Whether there will be any important additions between now and May 15 at the increased fee is problematical.

A. C. A. TO HOLD A SEALED BONNET TEST.

Beginning June 19 next, the Automobile Club of America will undertake a four days' test open to all listed cars, whether of domestic or foreign make. It is to be known as a "sealed bonnet" contest—a title that speaks for itself. But in addition to sealing the bonnets of the cars preparatory to the start, the transmission cases, coil boxes and sundry other parts will also be sealed, and no adjustments, repairs or replacements of any kind other than tires will be permitted during the course of the contest. There will be no restriction on either the fuel or water supply. The total distance is to be 600 miles for all cars except runabouts in Class A, for which the distance will be 700 miles, to be covered in daily stretches of 150 and 175 miles respectively. Each entrant will be required to furnish a competent technical observer who will be assigned to a car other than that of the entrant, and the assignments of observers will be changed each day. The prizes are to consist of silver cups to be awarded to the winners in each class, in addition to which certificates of performance will be awarded to those who desire them.

The classification is as follows:

Class A. Stock cars complete without tops listed at \$3,000 and over.

Class B. Stock cars complete without tops listed at \$1,500 and less than \$3,000.

Class C. Stock cars complete without tops listed at \$1,500 and under.

Cars in class A must make a minimum average speed of 18 miles an hour; in class B an average speed of 16 miles an hour, and in class C of 14 miles an hour; runabouts in class B being required to make the same average as touring cars in class A, or 18 miles an hour. Cars violating legal speed limits will be disqualified. Each car must be equipped with an odometer and must be placed in the custody of the committee in the club garage every evening and at which the start and finish will take place each day.

YALE'S AUTO CLUB HAS A MEET.

NEW HAVEN, CONN., April 29.—The first racing meet of the newly organized Yale Automobile Club was held April 27, at the Branford Driving Track. The feature of the meet was the performance of a 35-horsepower Oldsmobile roadster driven by William Folberth, an expert driver from the factory. Over 75 cars were present at the grounds, while the attendance was over 1,000. One of the features of the meet which created unbounded amusement was the "Beerobstacle races," in which the occupants of the cars dismounted at the end of each lap and each drank a stein of beer, re-entered the cars and repeated the performance for three laps.

In the finals of the three-mile open championship between a Stoddard-Dayton, L. C. Phipps, '07, driver, and the Oldsmobile, Folberth, driver, the Olds won in 4:45 2-5.

The race for the college championship between L. C. Phipps in a Stoddard-Dayton and G. H. Townsend in a Thomas was won by Phipps; time, 4:53 3-5.

Following the races the members of the club were banqueted in the Branford Casino, where plans were laid for a hill climbing contest to be held in May.

WILL DEMONSTRATE FOR THE DOCTORS.

ROCKFORD, ILL., April 29.—The great advantage of automobiles for the use of physicians is to have an unusual demonstration in this city next month on the occasion of the meeting here of the Illinois State Medical Association. The local auto agents have arranged to have a large variety of machines suitable for doctors' use, and their utility and capacity for time making, hill climbing and in traveling over all kinds of roads will be demonstrated. It is expected that 1,500 doctors will be in attendance at the meeting and will witness the auto tests. The country doctors rapidly are taking to the use of the machines.

RULES FOR THAT STOCK CAR RACE.

INDIANAPOLIS, IND., April 29.—The technical members of the Racing Board of the American Automobile Association met with a number of Western automobile engineers of prominence in this city last week. At the meeting steps were taken preliminary to drafting a set of rules intended to govern a race for stock touring cars which will be held some time after the Vanderbilt race. That little was accomplished at the meeting was due to the fact that Edgar Apperson, of Kokomo, one of the leading members at the conference, was taken suddenly ill. This caused an adjournment, and a meeting will be held in Chicago next week.

Only a few minor details were taken up and nothing definite was decided upon. The question as to whether or not foreign cars will be allowed to compete is one of the most important to be settled. It is understood that a number are in favor of foreign cars competing.

Henry Ford, who drove to Indianapolis in a Ford runabout from Detroit through rain and mud; E. R. Thomas, of Buffalo; and A. L. Riker, of Bridgeport, Conn., were the representatives of the A. A. A. at the meeting, while H. O. Smith and G. A. Weidley, of the Premier Motor Manufacturing Company; Elmer and Edgar Apperson, of the Apperson Automobile Company, and N. H. Van Sicklen, of Chicago, were others present at the conference.

It is expected that a large number of six-cylinder cars will be entered in the competition and these will be given special consideration in the plans. It is generally understood that a large number of Western manufacturers are intending to bring out six-cylinder cars for next season.

NEWS FROM THE INDEFATIGABLE MORGAN.

W. J. Morgan, writing from Jacksonville, Fla., denies the printed report that the Ormond-Daytona beach was ruined by a recent big storm. The Senator states that while the storm took away all the telephone poles and mile posts, and also the piers at Seabreeze and the small grandstand in front of the F. E. C. A. A. clubhouse, the beach itself came through the ordeal in fine shape.

Concerning the road from Jacksonville to the ocean, Mr. Morgan says: "The road will be built at once, and so confident was I of its worth that I agreed to build the highway for the tollgate privileges and sell it to the county at the end of five years at its first cost. However, the tollgate proposition did not meet with favor, and the County Commissioners are going to do the building and make it a free road. It will be at least 20 feet wide all the way to Atlantic-Pablo beach, some 20 miles, when it will then be possible to have a natural ocean boulevard of 60 miles or more, running direct to the North River, near St. Augustine, which either will be bridged or boat service provided by the time the road is constructed. An annual tournament may take place on the Atlantic-Pablo beach."

Mr. Morgan has gone to Galveston, Tex., to meet the Galveston Automobile and Business Men's League, inspect the beach at that place, and talk over the possibilities of a race meet next year.

OLDFIELD DID NOT BREAK TRACK RECORD.

Barney Oldfield's mile in :51 4-5, made recently on the Lakeside track near San Diego, Cal., was accomplished on a two-mile circuit, thereby placing it in the same class with Webb Jay's White steamer mile of :48 4-5, made at the Morris Park track, New York City, July 4, 1905. It will be remembered that the Morris Park track was 1.39 miles, the starting point for the mile being on the backstretch, and thus making only one turn necessary in reaching the finish wire. The Lakeside track is specially constructed for automobiling, and Oldfield believes that he will be able to drive his Peerless Green Dragon a mile in :46. The one-mile circular track record still remains at :53, held jointly by Oldfield and Walter Christie, the former having made his mark at Los Angeles, Cal., and the latter on the Empire City track, Yonkers, N. Y.

FIAT AMONG LATE ENTRANTS FOR GRAND PRIX

PARIS, April 22.—When Walter Christie cabled at the eleventh hour the entry of his front-drive car in the Grand Prix, the automobile world was convinced that no further entry fee would pass into the hands of the Sporting Commission. Automobile firms are human and are no more given to paying two thousand dollars where one thousand will do than the rest of us. There was thus a commotion in the upper room, where the business in connection with the Grand Prix is transacted, when, a few hours before the final closing of engagements at double fees, Emile Lamberjack walked in with a check for six thousand dollars as entry fee for three Fiat racers. A couple of months ago a formal declaration went forth from the Italian factories that neither Fiat nor Itala would participate in the French annual race. No reason was given, though it was generally rumored that there was dissatisfaction with the new conditions. France was disappointed, for the abstention of two of her most formidable rivals robbed the race of much of its interest. Emile Lamberjack was still more disappointed, for he looked upon the abstention as an acknowledgment of defeat. After a little hesitation he resolved on a bold course. At his own expense he ordered three racers to be built, commanded absolute secrecy, and at the last moment walked into the Automobile Club of France and paid over the double entry fee. The engagement has caused a sensation and created satisfaction all round, for such an entry adds considerably to the interest of the race.

But Fiat is not the only late comer. At 6 o'clock, within a few minutes of the closing of the books, Gustave Gobron crossed over the Place de la Concorde, mounted to the first floor of the club and handed to Secretary Sautin an engagement for one Gobron machine and a check for two thousand dollars in due and proper form. Within an hour the Grand Prix fees had mounted from \$34,000 to \$42,000, and the list of entries had gone up from 34 to 38. Although causing less sensation, the Gobron entry was as great a surprise as that of Fiat. Lancia, Nazzaro and Weilschott will, as last year, be in charge of the Fiat racers. The final list for the Grand Prix, no further additions now being possible, is as follows:

France, 24 machines, consisting of 3 Bayard-Clément, 3 Darracq, 3 Motobloc, 1 Corre, 3 Panhard-Levassor, 3 Renault Frères, 3 Lorraine-Dietrich, 1 Porthos, 3 Brasier, 1 Gobron.

Germany, 3 Mercedes.

Italy, 5 machines, consisting of 1 Marchand, 1 Aquila Italiana, 3 Fiat.

Belgium, 3 Germain.

England, 2 Weigel.

America, 1 Christie.

Forty-seven machines will rush round the Dieppe course on July 2, for in addition to the 38 Grand Prix racers there are nine smaller racers engaged in the Sporting Commission cup, seven of them being French and two Italian. Only three firms have entered for the tire competition run in connection with the race, but five other tire firms have engaged stands on the course, without taking any part in the competition. To distinguish between those tires taking part in the competition and those which are not, the former will be painted a bright yellow.

Lancia, Now Lucky, Will Set the Pace.

The wheel of fortune has at last favored Lancia. When lots were drawn to-day at the A. C. F. for starting positions in the race it was Lancia, the man whose engagement was sent in at the last possible moment, who was given number one, and with it the right to rush round the Dieppe circuit at 6 A. M. on the morning of July 2 with no one to hinder him or to stay his wild course. Number one is always looked upon as a position of honor, and there is no doubt that Lancia will take full advantage to be derived from a clear course on the initial round. D'Hespel,

on a Corre, takes second place, starting one minute after Lancia, and at 6.2 Wagner, the Vanderbilt champion, will rush over the line on his little Darracq, bearing number 3, which last year was carried to victory by Sisz on a Renault. This year Sisz starts ninth. Walter Christie has drawn twelfth position, and just behind him will be dare-devil Jenatzy with 13, of doubtful omen. Brasier has fared badly in the drawing, for his first machine starts seventeenth and his third one closes the procession.

An Original System of Numbering the Racers.

A new system of numbering the cars has been adopted this year. The cars are given a team letter and numbered one, two, or three according to the position they occupy on the starting list. Thus the Fiat team letter is F, and Lancia, the first starter, takes F 1. Darracq team letter is D, Wagner carrying D 1, Hanriot D 2, and Demogeot D 3. Walter Christie carries W C 1. There are thus seventeen machines with a team letter or combination of letters and number 1, eleven with figure 2, and ten with figure 3. This method of numbering has met with some criticism on the ground that it does not indicate the order in which the machines started. George Prade, the iconoclast editor, declares that it is a ridiculous arrangement, and that the only sensible plan would have been to number the machines from 1 to 38 and give a distinctive color or combination of colors for each team.

The following is the order of starting in the Grand Prix, the first machine being sent away at 6 A. M., the others leaving at intervals of one minute:

- | | |
|--------------------------------|--------------------------------|
| 1. Fiat, LanciaF 1 | 19. Darracq, Hanriot.....D 2 |
| 2. Corre, d'HespelC 1 | 20. Dietrich, Rougier.....L 2 |
| 3. Darracq, Wagner.....D 1 | 21. Bayard-Clément, |
| 4. Dietrich, Duray.....L 1 | GarcetBC 2 |
| 5. Porthos, Stricker.....P 1 | 22. MotoblocMB 2 |
| 6. Dufaux-Marchand, | 23. Renault, Edmond.....R 2 |
| F. DufauxDM 1 | 24. Germain, DegraisGE 2 |
| 7. Bayard-Clément, | 25. Panhard, HeathPL 2 |
| Albert ClémentBC 1 | 26. Mercedes, Werner.....M 2 |
| 8. MotoblocMB 1 | 27. Weigel, Weigel.....W 2 |
| 9. Renault, SiszR 1 | 28. Brasier, BarasB 2 |
| 10. Germain, Perpère.....GE 1 | 29. Fiat, Weilschott.....F 3 |
| 11. Panhard, Le Blon....PL 1 | 30. Darracq, Demogeot....D 3 |
| 12. Christie, | 31. Dietrich, GabrielL 3 |
| Walter Christie....WC 1 | 32. Bayard-Clément |
| 13. Mercedes, JenatzyM 1 | GaudermanBC 3 |
| 14. Weigel, Lee Guinness..W 1 | 33. MotoblocMB 3 |
| 15. GobronGB 1 | 34. Renault, RichezR 3 |
| 16. Aquila Italiana, | 35. Germain, Roch Brault..GE 3 |
| RichatA 1 | 36. Panhard, Dutemple...PL 3 |
| 17. Brasier, Barillier.....B 1 | 37. Mercedes, Willy Poegé..M 3 |
| 18. Fiat, Nazzaro.....F 2 | 38. Brasier, Bablot.....B 3 |

Starts will be made on the loop track, and not on the main course, the seventeen machines bearing number one being brought out at once and drawn up in Indian file, the second series with number two coming out later, and finally the third series. By this means the main track will be perfectly free. The racers engaged in the Sporting Commission Cup will be started two or three hours later, at intervals yet to be decided upon and in the following order:

- | |
|--|
| 1. Gillet-Forest, De la Touloubre.....GF 1 |
| 2. Darracq, CaffloisD 1 |
| 3. H. I. S. A., Moulin.....H 1 |
| 4. La Bulre, P. Dumaine.....LB 1 |
| 5. PorthosP 1 |
| 6. DarracqD 2 |
| 7. H. I. S. A., Baron de Caters.....H 2 |
| 8. La Bulre, Mottard.....LB 2 |
| 9. La Bulre, DessalagneLB 3 |

Official numbers must be immediately painted on the machines in either black on white or white on black. Elaborate precautions are being made to prevent violation of the rules. The night before the race the machines will be given their allowance of gasoline, the tank being filled and the surplus put into cans and

sealed. Each machine will be locked in a separate box and guarded all night by a commissaire. If the driver expresses a desire for a small quantity of gasoline to start the motor a quarter of a liter will be drawn from the tank and given to him separately. There will be a separate tire and gasoline station for each machine, and not for each firm, as last year, everything allowed by the rules being obtainable at the grand stand stations, and tires only at the second station, half way round the course. Eighty inspectors, or more than one per kilometer, will be stationed round the course to observe that no aid is given to the machines, and especially that they do not obtain gasoline from outside sources. As last year, all work on the racers, from the moment the start is given to the time when the contest is called off, must be performed by the driver and his mechanic only. At the second tire station the tires will be hung up on the outside of the barricade separating the stations from the course. Drivers will hastily grab new tires as they slow down for a second, throwing the old ones over the barrier.

Official measurement of the course shows that the total distance round is 47.8 miles; ten rounds will be covered in the Grand Prix, giving a total distance of 478.3 miles. Sporting Commission Cup racers will only cover six rounds, giving a total of 287 miles.

Britain's King May Go to the Races.

Hopes are high of King Edward witnessing the Grand Prix. Rumors have been afloat for some time that the King of England had considered the question and that a favorable decision was likely. Last week the sub-prefect of Dieppe and the mayor of the town left for London to use their influence in obtaining the presence of the British sovereign at the race and at the same time to make arrangements for the motor boat race across the channel from Newhaven to Dieppe, to be held in conjunction with the Grand Prix. Natives of the district are dissatisfied with the decision of the Automobile Club of France to open a large camping ground in the vicinity of the course, and declare that if this intention is persisted in they will withhold their subscriptions to the club. As the Dieppe district is contributing \$20,000 to the funds of the A. C. F., this body is obliged to pay some attention to the wishes of the inhabitants. Nothing has yet been officially announced regarding their reply to the anti-campers.

CHRISTIE RACER IS BEING TRIED OUT.

Walter Christie's Grand Prix racer made its first run on a quiet road near the factory this week. Excepting a leaky radiator, and a few details of little importance the test was most satisfactory, the machine showing remarkable speed and giving all that was expected of her from her builder. Walter Christie declares that a few slight alterations will be made and that the end of this week he will leave New York for a fortnight's thorough testing. It has been decided to use Diamond tires.

FRENCH SPRING WHEEL TEST.

PARIS, April 23.—There appears to be more interest on the part of the automobile public in the spring wheel problem than among wheel makers and inventors. Last year, when an exhibition and competition was organized in Paris for any type of wheel other than pneumatic, eleven machines were assembled, and three fulfilled all the demands of the test. This year there are thirteen starters, employing seven different systems, a smaller number than in the previous contest, only three of them being of recent origin. The test consists of a run from Paris to Marseilles and back, in four outward and four homeward stages, at an average speed of forty kilometers an hour. Repairs may be done on the wheels if necessary, but as there is an ever-watchful commissioner from a rival firm on board, who is enjoined to make a careful note of such attentions and report them to the jury appointed to examine the wheels on their return to the capital, drivers keep their fingers off as much as possible. The total distance to Marseilles and back is 1,300 miles, giving a daily average of 150 miles.

The competitors consisted of one Soleil, three Ducasble, three Elastes, two Edmond Levi, one Securitas, one Cosset, and one Sider. Securitas, Ducasble, Cosset and Elastes are, if not entirely new, at least newcomers in competitions of this nature. Elastes has come into general use during the past year, more especially on horse and gasoline cabs. Externally, the wheel does not differ from the ordinary type of pneumatic tire. Instead of being filled with air, however, there is an inner tube of rubbery composition made largely of glue, glycerine and chromatic salts. The outer shoe is forced on over this ring of composition. On the Securitas wheel a number of rubber balls of varying diameter and resistance, according to the nature of the car on which it will be used, are placed between the felloe and the outer rim. These balls are lodged in a chamber formed by the rim of the wheel, two steel beads solidly attached to the rim, and a strong steel collar holding the rubber bandage coming in contact with the road. This outer steel rim is of I-section, the two projections fitting into grooves on the felloe, and having a sliding movement. The rubber balls between the two give the necessary resiliency. There is a special arrangement to prevent the outer rim revolving on the inner, though not of a nature to prevent it being compressed.

Ducasble is a cushion tire with a number of independent air chambers, each of which has an air hole, out of which the air is forced when that part of the tire is compressed, and through which fresh air is drawn when pressure is released.

The Sider wheel consists of a shoe similar in external appearance to an ordinary pneumatic shoe, with a number of thin steel bands placed transversely to the rim, superimposed, but separated by layers of canvas. It forms a semi-metallic tissue, the springs forming the web and being united by a chain.

SECURITAS SPRING WHEEL.

THE DUCASBLE.

INVENTOR COSSET'S WHEEL.

MASSACHUSETTS REGISTRATIONS.

BOSTON, April 29.—Automobile registration in Massachusetts has shown a steady gain this spring, and for the first four months of the current year the registration with the highway commissioners is more than 300 cars ahead of the same months last year. Since the first of January there have been registered approximately 2,100 machines, against 1719 for the first four months of 1906. The number of licenses to operate, however, have not increased proportionately, indicating that not as many new owners are registered as last year. Since the first of last January there have been issued 824 ordinary operators' licenses, against 956 for the first four months of last year, and the registration of motorcycles remains about the same. There have been only 27 new manufacturers and dealers registered so far this year, against 58 for the corresponding time a year ago.

No Board of Examiners in Massachusetts.

The Committee on Roads and Bridges of the Legislature this week reported unfavorably on the recommendations of Governor Guild in his inaugural address. These were that a board of expert examiners be established to pass upon the applications of chauffeurs for licenses, and that a statute be passed giving pedestrians and horse-drawn vehicles the right of way over automobiles on the highways of the State. The report on both these recommendations was, "no legislation necessary." The highway commission already has sufficient power, if it wishes, to put applicants for chauffeurs' licenses through any sort of a reasonable test it may devise.

An Annual Registration, but Amount Undetermined.

The only legislative matter that is still unsettled is the bill to increase the fee for registration. As originally proposed this bill provided for a sliding scale of fees from \$5 to \$15 for pleasure cars based on horsepower. That feature of the bill, it is said, has been abandoned by the committee, and it has practically been decided to report a measure providing for a flat annual registration fee, the same for all sorts of pleasure motor vehicles. What the sum will be has not been settled, but it is stated that a majority of the committee favors a \$5 annual fee. This would provide approximately \$60,000, which is \$10,000 more than the amount which the highway commission estimates is necessary to make repairs on the highways of damage caused by automobiles.

WHAT'S DOING IN AUTO LEGISLATION.

MADISON, WIS., April 29.—All automobile bills have been practically killed. James T. Drought, of the Milwaukee Automobile Club, was exceedingly active in heading off unfavorable legislation and deserves great credit for his efforts.

ST. PAUL, MINN., April 29.—The State Senate has passed Senator Nelson's automobile bill after amending it so as to make the maximum speed in cities 15 miles per hour instead of 8.

LANSING, MICH., April 29.—The Secretary of State's office wants to inaugurate a new system of registering automobiles, compelling a comprehensive certificate to be issued for each machine, the original to cost \$5 and \$2.50 for a yearly renewal. There is also a provision for registering chauffeurs annually and providing them with badges at no additional cost, but their competency must be vouched for by two reliable persons.

PENNSYLVANIA REFUSES TO BE PROGRESSIVE.

PHILADELPHIA, April 29.—The Pennsylvania Constitution will not be amended in the interest of good roads. The bill to borrow \$25,000,000 to be devoted to the improvement of the roads of the State fell by the wayside last Wednesday when, by a vote of 91 yeas to 68 nays, it failed by reason of the two-thirds provision required for the passage of Constitutional amendments. The facts that the State has a big balance in the treasury and that several millions "graft" was gathered in on the new capitol without materially flattening the Commonwealth's pocketbook, were responsible for the failure.

BOSTON FIRE CHIEF'S STEAMER.

BOSTON, April 29.—Another important addition to the automobile corps of the Boston fire department is the steam car designed by Louis S. Ross and built in his factory at Newtonville, especially for the use of Chief Mullen of the department. Ross, besides being one of the best-known drivers of steam cars in the world, is also a fire crank, and for some time he has been endeavoring to construct an automobile for fire work. He finally interested Commissioner Wells, of the Boston department, and secured the order. The car in general appearance is a tourer, but it cost to build considerable more than Ross charges for his stock tourer, and in every part has been designed for fast and hard work. The frame, axles, springs and driving parts are all heavier than in the ordinary car, and the boiler, of the fire tube pattern, is 26 inches in diameter, while the two-cylinder vertical engine, it is claimed, will generate 75 horsepower and give a speed of 50 miles an hour. Such a speed has already been attained in trial runs and the car has climbed Parker hill, the worst grade in the city.

To protect the car from damage there is a bumper in front, and the car is equipped throughout with Kilgore shock absorbers. In the rear is a patent leather trunk in which are carried the coats of the chief and his aide, Lieutenant Webber, who has charge of

ROSS STEAM CAR BUILT FOR BOSTON FIRE CHIEF.

Chief Mullen in uniform and Fire Commissioner Wells in the rear seat; Lieutenant Webber, aid to the chief, and Charles Cosgrove in front seat.

the car. Under the rear seat are special compartments for the fire hats and rubber boots of the occupants of the machine. A speedometer, water, gasoline, air and steam gauges are placed on the dash, where there is also a special cut-out so that when the car is left alone at a fire it cannot be harmed by anyone who attempts to meddle with the machinery.

Both boiler and engine are carried under the hood, and Mr. Ross has exercised his ingenuity to a remarkable degree in providing arrangements by which every sort of a breakdown can be avoided. He has an arrangement, for instance, by which if the superheater is damaged wet steam can be used and every part is so made as to be quickly interchangeable. Under the front seat is a 40-gallon water tank, while in the rear is a 30-gallon gasoline tank. The air pressure is maintained mechanically and there is also an auxiliary air tank so that there is never danger of trouble from lack of air pressure. When the car is not in use the steam pressure is maintained by the pilot light, which always keeps up a sufficient head of steam to start the car at 25 miles an hour, and it is claimed by Lieutenant Webber that while the chief is getting on his coat he can have the car ready for a dash to the furthest section of the city at highest speed. The pilot light costs about 15 cents a day in gasoline.

A garage and repair shop has been opened at Brattleboro, Vt., by the E. R. Clark Automobile Company, of Springfield, Mass. The equipment is modern and complete.

A MERGER INVOLVING TIRE INDUSTRY.

There is a possibility of the affiliation of the United States Rubber Company with the Continental Rubber Company, which, if brought about, will unite the largest manufacturing and the largest rubber controlling bodies in one corporation.

Inquiries at the headquarters of the United States Rubber Company were met with the information that the merger was under consideration, and that an examination of the affairs of the numerous bodies affiliated with or controlled by the United States Rubber Company was being carried out. No definite action has yet been taken, and it is not likely that any definite move will be made for several months.

The amalgamation is of interest to the automobile industry from the fact that the United States Rubber Company controls some of the most important tire manufacturing concerns in this country.

The Continental Rubber Company holds the largest concessions of raw material in the world, some of which, in Mexico and on the Congo, have never been exploited. "Should the amalgamation be consummated, it will result in a reduction in the price of manufactured goods," declared the official of the United States Rubber Company.

A Rubber Affiliation Just Announced.

INDIANAPOLIS, April 29.—Charles H. Dale, president of the Rubber Goods Manufacturing Company, makes the first official announcement in his annual report of the affiliation between the Rubber Goods Manufacturing Company and the United States Rubber Company, which it is understood was brought about a few months ago.

The Rubber Goods Manufacturing Company is an organization of several manufacturers of rubber tires, including the G & J plant in this city, while the United States Rubber Company is composed of manufacturers of rubber boots and similar articles. It is said in the report that the affiliation of the two associations has resulted in considerable good to each, including better facilities for the purchase of crude material.

NASHVILLE, TENN., TRIES THE SHOW IDEA.

NASHVILLE, TENN., April 27.—A decisive impetus was given to automobile interests in Nashville this week, when, in connection with and as a feature of the Spring Festival, under the auspices of the Board of Trade, the automobile dealers and manufacturers' agents arranged an exhibit of cars. The garage of the Southern Automobile Agency was selected, and many examined the eleven makes of cars shown. The garage was beautified with palms and flowers.

A car that attracted much attention was the White steamer eight-passenger limousine. This car is the only one of its kind in the State, and was sold to W. J. Oliver, Knoxville, who will be remembered as the lowest bidder on the Panama Canal contract. Another car that called for admiration was the Dorris car, built by Preston Dorris, an old Nashville boy. Duncan R. Dorris, a brother of Preston Dorris, and manager of the Nashville Motor Car Company, himself personally demonstrated this car.

AN AUTOMOBILE SHOW IN DARKEST RUSSIA.

It seems that 1907 will go down into history as the year in which every country but Liberia and the Congo Free State held an automobile show. Spain makes her debut in this field this month, and now Russia has vitalized a project to do likewise. Consul-General Watts, at St. Petersburg, forwards a letter to the department from the chairman of the executive committee of the Automobile Club of Russia, requesting him to make known in the United States the regulations of the first international motor-car exhibition, to be held from June 1 to 17 under its auspices. The Russian Government has already granted special railway rates for all exhibits. The complete regulations, printed in French, are on file at the Bureau of Manufactures, where they are available to the trade.

FIRST AMERICAN AEROPLANE CONTEST.

Rules governing the competition for the *Scientific American* flying machine trophy, drawn up by a special committee of the Aero Club of America, stipulate that the competition shall be open to all nations, that it shall be held annually, and that the first contest shall be at the Jamestown exhibition on September 14, 1907. Entries are received at the Aero Club of America prior to September 1. Heavier-than-air machines of any type whatever are eligible for the competition, the trophy going to the one covering a distance of one kilometer in the shortest time and with the best display of stability and ease of control. The flights shall be made in calm air if possible, the start being made against the wind. If the trophy is won by the representative of a foreign aeronautical club, this club may become the custodian of the trophy, but all competitions, even if held abroad, must be carried out under the rules used by the Aero Club of America in the competition held here.

M. CHARRON WEDS CLÉMENTS DAUGHTER.

PARIS, April 22.—It was a strictly automobile gathering that assembled at the *mairie* of Neuilly-sur-Seine to celebrate the marriage of Ferdinand Charron, winner in the first Gordon Bennett Cup contest and the head of the firm of C. G. V., with Mademoiselle Jeanne Clément, daughter of M. Clément, founder of the Bayard-Clément firm. Ferdinand Charron, in addition to being one of the most important business men in the Paris automobile world, is an all-round sportsman, has been successful in bicycle and automobile contests, and lately has ridden his own horses to victory in races at Longchamps against the most experienced European jockeys. The brilliant ceremony was attended by representatives from nearly all the important French automobile firms, among the guests being Marquis de Dion, Louis Renault, René de Knyff and Dominique Lamberjack. The entire wedding party arrived in C. G. V. and Bayard-Clément automobiles.

NO HOPE FOR ITALY IN THE AERO CUP RACE.

PARIS, April 23.—All hope of Italian participation in the Gordon Bennett balloon contest at St. Louis on October 19 is at an end as the result of a recent decision of the International Aeronautical Federation. It will be remembered that Italy sent in an entry for the race several weeks after the official date of closing, and that their engagement was refused. A special appeal was made to the International Federation, which is alone authorized to judge in such a matter, on the ground that unforeseen circumstances had prevented the entry being sent in according to regulations. After due consideration the Federation declared that they regretted that they were obliged to apply the rules rigorously, and must in consequence refuse the Italian entry.

LIEUTENANT LAHM ILL WITH TYPHOID.

According to despatches from France, Lieutenant Frank P. Lahm, who is undergoing a course of special training at the French military cavalry school at Saumur, is ill with typhoid fever. Lieutenant Lahm was selected, with J. C. McCoy and Alan R. Hawley, to represent the United States in the balloon race for the Bennett Cup from St. Louis next October. Should he not be able to take part in this contest as the result of the illness, his place will be taken by one of the three substitutes yet to be named by the Aero Club of America.

AN AIRSHIP WHICH CARRIES TEN.

A cable despatch from Paris announces that a giant aerostat named the *Eagle*, with a capacity of 4,150 cubic meters, made a successful ascent from the grounds of the Aero Club at Saint-Cloud. There were ten of the best aeronauts of Paris in the car, among them being Santos-Dumont. The balloon vanished to the southwest before a fair breeze. M. Bahan, vice-president of the Aero Club of France, is the owner of the *Eagle*.

FRANKLIN MOTOR HAS INDOOR TEST.

Just to demonstrate that the Franklin air-cooled motor was everything that its name would indicate, the New York City agents, Wyckoff, Church & Partridge, mounted a complete 12-horsepower Franklin car on stilts at their establishment at Fifty-sixth street and Broadway last week and set it going in the presence of a number of technical men and newspaper representatives. It was started at 3 p.m. Wednesday afternoon by E. L. Ferguson, chairman of the technical committee of the New York Motor Club, who thereupon sealed the carbureter and ignition adjustments so that they could not be tampered with in any way, thus making the test particularly severe as the motor could not be "nursed" in any way to keep it going. The sealing was attested to by a committee composed of Mr. Ferguson, Sam Butler of the Automobile Club of America, and Alex Schwalbach of the Long Island Automobile Club. The observation committee consisted of Al Reeves, manager of the A. M. C. M. A., Fred Wagner and D. A. Ward. The motor was run at 400 r. p. m.—an equivalent of 9 miles an hour—without a fan and in the closed salesroom, thus depriving it of the most efficient of cooling factors, convection. It continued to run for 44 hours, which was equivalent to 540 miles, without other attention than a supply of gasoline and oil, at the end of which period it was stopped purposely. Wyckoff, Church & Partridge tried the Franklin motor beforehand, and had had it running steadily night and day since the previous Friday. It was simply stopped for a short time on Wednesday to go through the formality of sealing, so that when it was finally stopped it had been running a whole week in a closed room—something that speaks well for the Franklin auxiliary exhaust, which made the feat possible. The exhaust gases were piped out of the room.

EXPORTS BEGIN TO DOUBLE ANNUALLY.

While it is to be regretted that no statistics of automobile production are kept in this country, some idea of the rate at which the annual output is increasing may be had from the export returns. For the month of March, 1907, the total was \$545,347, representing an increase of more than \$250,000 over the same month of but a year ago, when the total was \$293,561. This sum is composed of the value of 307 complete cars, reaching a total of \$493,425, and parts to the extent of \$51,922. And the most striking feature of the report is to be found in the fact that a very large part of the increase is to be found in the returns from automobile-producing countries. The amount sent to Great Britain, for instance, more than doubled in that time, increasing from \$70,414 for March, 1906, to \$146,621 in the present year, while to France it more than trebled, the figures being \$16,035 and \$65,813; to Germany the increase amounted to but \$3,000 in round numbers, though to other Europe there was a jump from \$12,207 to \$59,573. Mexico, British North America and South America also show substantial increases.

During the period of nine months ending with March for three years past the increasing totals tell a similar story. For 1905 this was \$1,638,601; 1906, \$2,064,874, and 1907, \$3,418,593, the last-named total being composed of the value of 1,889 complete cars amounting to \$2,965,284 and \$453,309 worth of parts. The report in detail, showing the increase in March, 1907, as compared with 1906, and for the eight months ending with March in those two years follows. Prior to July, 1905, automobile exports were not considered of sufficient moment to state in detail.

EZRA KIRK.

Ezra E. Kirk, sales manager of the E. R. Thomas Motor Company, Buffalo, N. Y., for the past year and more, has resigned, and his address is now 915 Jefferson avenue, Toledo, O. Mr. Kirk is one of the pioneers of cycling who took to automobiling at its inception and is well known throughout the trade. His plans for the future he is not as yet prepared to announce, but his continuance in the trade is a certainty.

A VISIT TO BATTLE MONUMENT, WEST POINT, IN A PEERLESS.

[The monument is erected to the memory of officers of the United States Army, who have been killed in the service. Battle Mountain is in the background.]

NEWMASTIC WORKSHOP, WITH DEVICE FOR FILLING TIRES.

A SUBSTITUTE FOR AIR IN TIRES.

Substitutes for pneumatic tires have so frequently been introduced that the practical automobilist has ceased to prick up his ears when a new one is brought forth with beating of drums. Some months ago a spongy preparation for filling ordinary pneumatic tires was put on the French market and is at present being used with considerable success, more especially on horse and gasoline cabs. Avoiding details, it consists of a composition composed of glue, glycerine, and chromatic salts, liquefied, poured into the tire and allowed to set. The composition can be made as spongy or as hard as desired, and providing it does not lose its resiliency with use, forms what is claimed to be an excellent substitute for air-filled tires. We have not been able to watch the performance of the French product for long periods, but the extent to which it is being adopted for public vehicles in European capitals would seem to indicate that it satisfies.

It was somewhat of a surprise to discover that a substitute for the pneumatic tire, similar in principle, but improved in detail, to the article employed in Europe, had been manufactured in this country for over four years, considerably antedating the French rival. C. D. Nirdlinger had the honor of inventing a preparation for use in tires, to which he gave the title of Newmastic. For several years he worked in a quiet way, filling tires that were sent to him, established a couple of branches in distant cities, but failed to make his product known outside of a limited circle.

Only a few months ago Nirdlinger's patents were brought to the notice of interested capitalists, and immediately arrangements were made for lifting them out of the rut in which they had for so long been held.

In a store at Sixty-eighth street and Broadway, the Newmastic Tire Company has established its New York headquarters, and it is there that ordinary pneumatic tires for lordly touring machines and humble bikes are transformed from air-filled to Newmastic-filled. On the occasion of the visit of the representative of *THE AUTOMOBILE*, a group of workmen, with the inventor at their head, were just about to operate upon a batch of tires of all sizes and conditions. On a raised platform was a large copper-jacketed vat with a circular gas jet beneath it, in which for several hours a mixture of glue, glycerine and chromatic salts had been gently simmering, all the time stirred up by a revolving paddle within the vat. A glance at the illustration will show the arrangement of the vat.

Two men bearing a can of chemicals in solution mounted a ladder to the upper platform, poured the contents into the vat, and descended. A minute later the paddle was stopped, and a cock opened at the base of the vat, allowing the hot composition

to run out into another tank immediately beneath. From the lower tank a central outlet pipe runs with a number of branch arms, each one fitted with a tap. Over the piping were suspended a number of automobile wheels, fitted with pneumatic tires. They were a motley group; the smallest was for a bicycle, the largest for a big Panhard touring machine. Each one had had its valve drilled out, and was connected up to an arm of the main outlet pipe at the base of tank. A couple of needle valves had been pushed into each tire and were held there by a sleeve. On a given signal the flow of the hot composition was stopped, the inlet closed hermetically and compressed air allowed to enter the lower vat from a huge tank on an elevated platform. A few seconds later air could be heard hissing out of the valves pierced through the tires, and immediately after the grey composition began to issue. A half turn of the needle and the valves were closed, and each man stood with his fingers on the tire awaiting the moment when experience told him that it was necessary to shut off the supply. All that then remained to be done was to disconnect the tire valve from the pipe, take the wheel down, pull out the air plugs, which, being no thicker than a fine pricker, left a hole of no importance, clean off any of the composition which had oozed out about the inlet valve, fix the wheel on the car and go on the way rejoicing.

One of the qualities of this composition is that it sets almost instantly into a springy, rubbery mass, so that there is no delay in changing from air-filled tires to those provided with Newmastic. It is claimed that the composition will not harden with use; that, indeed, its tendency is to get slightly softer as it increases in age. Experiments with the hot flame of a soldering lamp proved conclusively that it could not be melted with heat. A section was placed in the flame for a few seconds; it frizzled, but would not melt, and apparently lost none of its resiliency by the application of the heat.

The first objection made to the preparation would be that of weight. If it were used on a light motorcycle the objection would hold. But if applied to a medium weight touring car or runabout there would be no increase, while if it were a very heavy and powerful machine a gain in weight would be made. Generally the weight of the resilient composition put into the tires is equal to the extra shoe, jack, inner tubes and repair outfit carried on the machine. Weight is taken off the machine and put on the wheels in an ordinary case; there is a distinct saving on the heaviest types of automobiles.

TRYING OUT THE POPE-TRIBUNE RUNABOUT.

CUMBERLAND, Md., April 27.—The hills of Maryland supply excellent trying out territory, and the Pope Manufacturing Company's plant at Hagerstown therefore has an ideal location. H. L. Pope, its general manager; V. M. Palmer, the superintendent, and eighteen others of the Pope staff came to Cumberland with ten 16-20-horsepower Pope-Tribune four-cylinder runabouts recently on a testing trip. At Sideling Hill it was necessary to ford the creek with the water up to the hubs of the cars. The party stopped over night in Cumberland.

POPE-TRIBUNE CAR TESTING PARTY AT CUMBERLAND, MD.

REO SUBMARINE MAKES DEEP SEA RECORD.

When sending a car off on a record-making or breaking trip on the Pacific Coast, there are more things to be thought of than gasoline, oil, tires and spares—many more—and not the least of them is the fact that, owing to the lamentable lack of bridges

H. M. HANSHUE IN HIS REO.

and other signs of civilization, there are apt to be many times when the car will find itself under water. Now the modern automobile, while amphibious to a certain extent, is not a diver, and when the wet begins to rise above the footboards there is usually a muffled sigh and a gurgle that sounds the death knell of the carbureter as well as the ignition system.

But he of the alliterative cognomen—Harris

Hanshue—took this into account when he assayed to do things to the Oakland-Los Angeles record in a Reo. On that stretch of 500 miles there is plenty of water, and lots of it pretty deep at that. He turned his car over to the mercies of L. T. Shettler before starting, and the latter used some garden hose with good effect; in other words, he brought the carbureter air intake and the exhaust above “sea level,” as shown by the protuberance sticking above the car in the accompanying photographs of the exploit. In addition, every part of the car susceptible to moisture was wrapped with tape, shellacked and then wrapped again. As a result, the 500 miles of mud, roughness and deep fords were made in two days and fifty-four minutes, every foot of it being covered by the little Reo under its own power, which is more than a mere record for a two-cylinder car. The time really gives no idea of the pace at which obstacles were overcome, for some seven hours were lost at Tulare by making a roundabout circuit on the wrong road and re-entering the same town that much later. Failure of the acetylene gas at Livermore accounted for more lost time, as in addition to darkness there was also fog.

EXHAUST CARRIED ABOVE SEAT BACKS.

Failure of the acetylene gas at Livermore accounted for more lost time, as in addition to darkness there was also fog.

CORLEW MAY HEAD NEW ENGLAND CONCERN.

Boston, Mass., April 29.—It is rumored that Frank S. Corlew, who organized the Dragon Automobile Company, of Philadelphia, and who lately resigned his position as vice-president and sales manager, has been approached by New England capitalists to head a proposed automobile industry, which, it is understood, will be one of the largest automobile companies in the United States. It is said to be their intention not only to build low-priced pleasure vehicles, but taximeter cabs and light delivery wagons, and the factory to be located in or near Boston. Full details and announcement of the proposed industry is expected to be given out in a short time.

The city hall commission of Newark, N. J., has decided to erect a garage in the rear of the city hall, which will measure 56x96 feet, and be two stories high.

A. M. C. M. A. SECURES REDUCTION IN RATES.

By an extremely illogical interpretation of a rule established by the Pennsylvania ferries before the advent of the automobile, a loaded five-ton truck was ferried for a charge of 90 cents, but one carrying machinery had to pay \$4 a trip. The gasoline-driven commercial vehicle contained machinery, ergo it had to pay the four-dollar rate over that ferry. In construing the rule, the officials never considered whether it meant machinery in or on the truck, and stretched it to cover both. The reason for charging more in the case of a truck loaded with machinery was due to the fact that very heavy pieces were frequently thus carried, and occasioned trouble and delay by being unable to leave at the other end owing to the grade of the bridge at low-tide.

As this was an unjust discrimination against the users of commercial vehicles, the freight committee of the American Motor Car Manufacturers' Association, working in conjunction with J. H. Wood, general manager of the Merchants' Express and Transportation Company, took up the matter with the Pennsylvania Railroad officials, and has succeeded in having the tariff reduced to 38 cents a trip, or, when bought in hundred lots, 30 cents a trip, as obtains on other ferries. When loaded with machinery the usual additional charge will be made.

GIVING INVENTIVE GENIUS ITS JUST DUE.

In the article on “The Importance of Facilities in Touring,” appearing on page 586 of the April 4 issue of THE AUTOMOBILE, Mr. Ellsworth is credited with being the designer of the ingenious arrangement for carrying luggage on a touring car. The honor is due to Dr. Wood McMurtry, an American resident in Paris, who designed this body and put it on the market under the title of “La Routière” touring body. It was Mr. Ellsworth who bought the car from Dr. McMurtry and introduced it into this country.

HAYNES RUNABOUT TO BE 30 INSTEAD OF 50 H.P.

After trying it out very thoroughly, the Haynes Automobile Company, Kokomo, Ind., have concluded not to market a duplicate of the high-speed runabout which was used in the Vanderbilt cup race last, except to order. Instead, they will specialize their 30-horsepower Model S chassis for the same purpose, the 50 having proved to be unnecessarily high-powered for the weight of the car. The new car, which is pictured in the accompanying photograph, is to be termed the Haynes semi-racer. It has practically unlimited speed and climbing power, and, with its great flaring fenders, thoroughly protecting the passengers from flying mud and stones, it is a snappy and serviceable looking car. A rumble seat in the rear is provided on top of the tool box, which is a permanent fixture, beside which there is a rack for a trunk or dress-suit cases. The finish is an attractive gray, set off by black striping.

HAYNES SEMI-RACER RUNABOUT, 30-HORSEPOWER.

FARMER'S AUTO, DESIGNED SPECIALLY FOR RURAL RESIDENTS.

AUTOMOBILES FOR THE AGRICULTURIST.

Though looked down upon with a curious and more or less kindly tolerance by the average autoist, the high-wheeler with its square body and abrupt dash, so closely approximating the ideal of horseless vehicle from which the present type of automobile was evolved, has come to stay. More than that, it represents a factor which, in the course of a few years, is bound to become of great importance. It is not too much to say that with the passing of another decade there will be more of this type by far in the hands of users than any other; they will outnumber the cars whose chief distinguishing features are luxury and speed, many to one. A car such as that shown by the accompanying photograph, is hardly as complicated as much of the present-day agricultural machinery used on large farms, and is, in consequence, not alone readily understood by the farmer and his sons, but by the village blacksmith as well, to whom it is bound to be taken once beyond the province of home repairs.

Its makers, the International Harvester Company, Chicago, Ill., know the farmer's needs and the farmer's limitations—better, probably, than he knows them himself—and have borne them in mind throughout the design of the vehicle, which is appropriately called the Farmer's Auto. It is expressly designed and constructed, not only for the rural highways over which it is to be run, but also for the rural owner who is to run it. The motor is a four-cycle air-cooled engine and is of the horizontal, two-cylinder opposed type. It is located centrally under the body in an accessible position. The cylinders measure 5 by 5 inches bore and stroke respectively, and provide ample power to carry the vehicle over the roughest of roads or steep hills at a speed varying from two to twenty miles an hour. Every part is of the most substantial nature; long pistons and an extra heavy crankshaft supported on liberal-sized bearings distinguishing the engine, while one-piece steel drop forgings form the front and rear axles. The valves are all in separate cages and are easily removable for inspection, while lubrication is automatically taken care of by a 10-feed mechanical force-feed lubricator. High-tension ignition is employed, the coil being mounted on the dash in a dust-proof case. The wheels are of the well-known Sarven type and are 40 inches in diameter on the front and 44 inches on the rear; they are shod with 1 5/8-inch solid rubber side-wire tires. The engine lies parallel with the body and drives by a single chain to a countershaft from which the final drive is taken to the rear wheels by double side-chains. Simplicity and accessibility have been studied and the results applied at every point, as is evident from the fact that the transmission is readily removable from the body for inspection or repair; the friction clutch is very simple and dependable and the differential is placed on the countershaft as is done on the most approved heavy types using a side-chain drive. Bronze and steel gears of substantial proportions are em-

ployed, running in amply large and long bearings, while all parts subjected to severe wear are case-hardened. Double elliptic springs are used both front and rear for the suspension.

It is evident from the illustration that while conforming to the farm standard of simplicity and durability, the matter of outward appearance has not been overlooked. The tilted wheel steer and the single-lever control, as well as the slight backward rake given the high-backed seats, give the car a business-like look that is more often lacking in this type of car than not. The seats are comfortably upholstered and finished with Pantasote, the rear seat being made detachable. The regular equipment consists of a pair of headlights and a taillight as well as a horn; the top is extra.

4,000 MILES, WHITE VS. ROLLS-ROYCE.

LONDON, April 20.—Much talk has been going on recently regarding the gauntlet thrown down by Mr. Frederick Coleman, English representative of the White steam car. There can be no doubt that all who are interested in the progress of the motoring industry will watch the performances which the following acceptance of the challenge will bring forth:

To the Editor of "The Daily Telegraph."

Sir—Referring to Mr. Coleman's challenge regarding a 4,000 miles' trial between a 30-horsepower White steam car and a 40-50-horsepower six-cylinder Rolls-Royce car, I think that most of your readers will agree that if the question of steam vs. petrol is to be fought out, no better car can be found to represent the steam interests than the White steam car, and being interested in the manufacture and sale of the six-cylinder Rolls-Royce car, I am naturally delighted that "A Member of the London Stock Exchange," in suggesting this competition, should have selected the Rolls-Royce to represent petrol, and that in the Rolls-Royce, Mr. Coleman acknowledges that he has a fit competitor.

Unhesitatingly I accept Mr. Coleman's challenge, on the understanding that fundamentally the trial is to be a test of trustworthiness, and with a view to deciding which is the better type of luxury-touring carriage.

I should like to be the first to point out in this connection that the selling price of the chassis of the 30-horsepower White steam car is £675, whereas, the selling price of the chassis of the 40-50-horsepower six-cylinder Rolls-Royce is £950, or with magneto, £980.

This difference in selling price will not, I hope, prevent Mr. Coleman from proceeding to formulate a system of classifying results which may be such as will satisfy the champions of both steam and petrol, and which can be accepted by me.

My hope is that we may be assisted in this task by suggestions from your readers, I am, sir, yours, etc.,

CLAUDE JOHNSON.

WALTHAM CARS SELECTED BY POST OFFICE.

Since learning the results of the long and exacting test to which the Orient buckboards were subjected in the rural free delivery service last summer, the Post Office Department has reversed its former decision of not permitting carriers to use automobiles of any nature without special permission, because "they were unreliable and did not serve a route with regularity," and has made one of the Orient 4-horsepower buckboards fitted with special pigeon-hole carriers as used in the tests, a part of its exhibit at Jamestown. In addition to thus upholding the car as typifying the most modern and economical as well as the most expeditious method of making rural deliveries, they have gone further and ordered two of the Waltham 8-horsepower delivery cars with regulation screened mail-wagon bodies, which will be used for transporting mail pouches between the Exposition grounds and the railway and steamship terminals. This approval of the Waltham cars as being representative of a maximum of economy and dependability in service is of much more significance than would appear on the surface, as the step was taken entirely on the initiative of the Government officials and without any solicitation to that effect by the manufacturers, the Waltham Manufacturing Company, Waltham, Mass.

The new Detroit store of the Winton Motor Carriage Company is located at 736 Woodward avenue. The company took possession on May 1.

BRIEF ITEMS OF NEWS AND TRADE MISCELLANY

A typographical error appeared in the advertisement of the Electric Vehicle Company, printed in the last issue of THE AUTOMOBILE. The price of the Mark XLVIII standard touring car should have been \$3,000, as stated in the current announcement of the same manufacturers.

The Reo Bird which holds the world's mile record for middleweight cars will make its appearance on the track again this spring. The Bird was designed by R. E. Olds, and built by the Reo Motor Car Company, from whose plant it was shipped to California this week. This year it will make its debut on the Los Angeles track during the race meet to be held there May 4.

James Joyce, who recently made public his opinion that a rule should be adopted for the Glidden tour this year looking to the sealing of the bonnets of the cars, has shown that he has the strength of his convictions by being the first to enter a car in the Automobile Club of America's four-day contest, to be run next June, under rules of this nature. He will drive a 40-h.p. Berliet.

On a recent tour through Germany and Austria to the Dolomites in his Winton, Dr. Wm. A. Spring, an American dentist residing in Dresden, visited Oberammergau, where the Passion Play is held every ten years. "We tried to see Anton Lang, who took the part of Christ," writes Dr. Spring, "but he was away, setting up a porcelain stove. We found 'Caiphas' and 'Judas' at home, and they received us very cordially. 'Judas' is said not to like his part."

Blood Bros. Machine Company, of Kalamazoo, Mich., manufacturers of universal joints and steering gears, have again found it necessary to increase their facilities to keep up with the rapidly growing demand. This time they have purchased a tract of land on Ransom street and the South Haven railroad and have moved into the factory buildings that were located there. With the new buildings they are putting up, they expect to have double the capacity for 1908 that they had at the beginning of this year.

That the gasoline truck is coming into its own in New York City is evident when Arnold, Constable & Co., who were pioneers in the adoption of the electric vehicle for delivery purposes, have come around to its favor. They have recently placed an order for four Maxwell delivery cars. What this means in the way of expediting service as well as reducing the cost of delivery, particularly on the heavy item for labor and maintenance, is apparent from the fact that nine electrics now in service permanently displaced 33 horses.

A new tire for motor trucks and commercial motor vehicles, very striking in appearance because it is made of white rubber, and for which much is claimed, has been developed by the Diamond Rubber Company. The tire is made in the well-known side wire type. It is extremely resilient, due in part to the

fact that it is made entirely of new and very elastic rubber. This, of course, is a factor tending to reduce the consumption of power and consequently increases the mileage, particularly that of electric vehicles. All tests indicate that this tire will attract marked interest in the commercial vehicle field.

"Troubleless Touring" abroad evidently appeals to many autoists, for Cecil Hodgman, manager of the foreign touring department of Smith & Mabley, Inc., is being overwhelmed with inquiries from all over the country. Several clients of this department are already enjoying the "Simplex" life on the other side of the pond and a number of Simplex cars have been chartered for the coming summer. The ease and certainty with which such a trip can be undertaken appeals to those owners of cars who do not regard a foreign trip favorably owing to the difficulty of shipping and the formalities involved, while to those of the non-autoing fraternity there is nothing to equal it.

Quite on a par with that story of the man who, failing any gasoline, kerosene, alcohol or sundry other fuel, ran his car home by breathing into the carbureter after taking a cocktail or two, is this one of C. W. Kelsey, formerly sales manager of the Maxwell-Briscoe Company. After the last Vanderbilt Cup race he found the gasoline tank empty with the car stranded in the Long Island woods. However, noticing the condition of the roads which had recently been oiled for the race, resourcefulness, such as automobiling proverbially inspires, came to his aid. It was the work of but a moment to disconnect the suction pipe of the motor and extend it to the road, whereupon cranking immediately started the motor and it ran perfectly on a mixture of —. The next member of the club is requested to step up and tell his.

NEW AGENCIES ESTABLISHED.

An agency for the Reo automobile has been secured in Augusta, Ga., by A. S. Ledbetter, with offices at 524 Broad street.

C. H. Foster, president of the Cadillac Company of Illinois, has been appointed Chicago and Western representative for the French electric automobile Gallia, manufactured near Paris by the Société Electrique des Voitures Gallia.

Arrangements have been made for the handling of the complete line of Waltham touring and runabout cars, also Waltham Orient buckboards, in Northern Indiana and Southern Michigan by the South Bend Automobile and Garage Company, at 228 South Lafayette street.

The Fawkes Auto Company, formally opened its new establishment on West Sixth street, St. Paul, Minn., last week. M. E. Woods, who formerly managed the local branch of the company when it had an establishment in Fifth street, will be the manager of the new place. The concern handles the Rambler, National,

Glide and Holsman gasoline cars and the National electrics.

The Acme Motor Car Company, of Reading, Pa., which was recently reorganized, has started on an aggressive sales campaign. Up to the present the following agencies have been appointed: Scull-Morris Motor Company, Philadelphia, Pa.; Boston Motor Company, Boston, Mass.; Theo. E. Schulz, New York City; Standard Motor Car Company, San Francisco, Cal.; John M. Larsen, Chicago, Ill.; F. W. Kavanaugh, Troy, N. Y., and central portion of New York State; Pecos Auto Company, Pecos, Texas, and vicinity.

PERSONAL TRADE MENTION.

J. L. Straub, secretary-treasurer of the J. S. Bretz Company, of New York City, will sail for Europe early in May. While abroad Mr. Straub will visit the factory of Fichtel & Sachs at Schweinfurt, Germany, manufacturers of the F. & S. annular ball bearings.

John E. Miller has been appointed superintendent of the works of the Deere-Clark Motor Car Co., Moline, Ill. Mr. Clark has a reputation for surrounding himself with strong men and this latest appointment adds to his record. Mr. Miller has been actively engaged in the manufacture of automobiles for a number of years.

The J. S. Bretz Company, of New York City, have secured the services of Harry J. Porter, of Rochester, N. Y., who will make his headquarters in Detroit and will cover the Western territory in the interests of the F. & S. annular bearings, Hartford universal joints and other lines the sale of which the Bretz Company controls.

Burton Parker, advertising manager of the Fisk Rubber Company, Chicopee Falls, Mass., is going the rounds of the principal branch offices of the company to obtain material for the "Pneus," the entertaining and instructive booklet that the company issues monthly. Copies are sent gratis on application to anyone interested in tire lore and the newest things in the field of rubber.

A. F. Justin has resigned as manager of the Penn Auto Supply Company, of Philadelphia, to take charge of the Providence branch of the Angier Company. The latter's establishment in that city has just been remodeled and enlarged, giving double the amount of floor space formerly used. In addition to the regular lines of automobile supplies, motor boats and boat supplies have been added.

F. L. Thomas, formerly local sales manager for the H. H. Franklin Manufacturing Company at Syracuse, has accepted a position as branch manager at Chicago for the Franklin Automobile Company. Mr. Thomas is well known in the automobile trade, having been associated with the Fredonia Manufacturing Company and also held the position of branch manager for the Knox Company at Buffalo.

INFORMATION FOR AUTO USERS.

The Breech Block Plug.—There are few things more exasperating than to have a plug that has gone wrong stick in the cylinder and refuse to budge despite every effort that can be brought to bear to get it out and particularly in the case of single and two-cylinder cars as

THE BREECH-BLOCK PLUG AND ITS CLIP.

further progress is impossible. With the Standard breech block plug, made by The Standard Company, Torrington, Conn., it is possible to remove and clean four plugs and return them in the space of sixteen seconds by the watch. It is especially valuable on old cars not provided with compression relief cocks in the cylinder heads, as it provides a means of injecting kerosene with equal convenience. It has numerous other advantages in addition, not the least of which is its round enclosed end preventing a cracked or chipped porcelain from falling into the cylinder and doing expensive damage. This protection also prevents burning off the glazed end of the porcelains and renders them easy to clean and long-lived. In connection with the "Breech-Block" clips, which snap the connecting wire onto the plug end in a jiffy, the breech block plug is a combination that is hard to beat for convenience and all round handiness.

Puncture Proof Tires.—The recently organized Akron Pneumatic Tire & Protector Company, Akron, O., is now placing on the market a new puncture proof tire and an extensible tread pneumatic

GREENWALD EXTENSIBLE TREAD TIRE.

tire, both of which are the inventions of L. Greenwald, formerly superintendent of the repair department of the Goodrich Rubber Company's works. The extensible tire is built on a new principle in

that it is designed to take the sudden heavy pressure caused by the tire striking an obstacle on the rubber instead of the fabric, thus preventing ruptures. This is provided for by a so-called hinged portion in which the fabric is omitted and replaced by rubber, which also permits the tire to have a greater heat-radiating capacity. This plan of building up the tire, which is shown by the accompanying illustration, Fig. 1, is also claimed to permit greater compensation for different loading than ordinary tires. The puncture proof type of tire is shown in Fig. 2; the tire is rendered impermeable by means of three layers of copper-plated steel discs placed in strata of rubber in such a manner as to present a

GREENWALD PUNCTURE-PROOF TIRE.

practically continuous band, this also making the protector of a very flexible nature, so that it does not interfere with the resiliency of the tire. This protector is so made that it can be interposed between the outer case and the inner tube, so that it may be readily removed whenever desired. Mr. Greenwald, who heads the new company, has also devised a reinforced inner tube with a fabric envelope designed to eliminate pinching by the clips or beads, which will also be manufactured. An active demand for its products is reported.

Stewart Speedometers.—Automobile manufacturers are not alone in taking time by the forelock by getting their 1908 models on the road ten months ahead of time. The Stewart & Clark Manufacturing Company, 502 to 520 Diversey boulevard, Chicago, announce that having booked orders for all the 1907 models of the Stewart speedometers that they can possibly turn out, they are now booking orders for the 1908 model, which will be made in four styles, 50-mile, 60-mile, 90-mile and 120-mile dials. This series will be fitted with the new swivel joint, which permits the flexible shaft to be carried straight back along the frame to the dash without the necessity of passing through or under the springs, thus doing away with the right-angle construction usually required, which adds a most attractive feature to the Stewart.

The accompanying illustration reveals the internal construction of the new 1908 model. The spindle or central shaft is made of selected steel hardened and ground and is mounted on ball bearings. An exceptionally long coiled spring of large diameter is employed to return the

indicator hand to the starting point. The steel shoe for moving the indicator is made file-hard. Every part is of the most substantial construction, thus insuring long life. The bevel gear angle-joint on

MECHANISM OF THE STEWART SPEEDOMETER

the instrument permits the flexible shaft to be carried down close alongside the dash and in connection with the new swivel joint makes the Stewart installation on the car an ideal one in every respect.

The Auto Light.—Considering that the car has always carried the necessary battery and coil equipment for electric gas lighting, it seems strange that some inventor has not taken advantage of them to apply it to the lighting of the acetylene headlights long ago. It has remained for the Rolfe-Fox Company, Livingston Building, Rochester, N. Y., to provide

such a device in the shape of the Auto Light, by means of which it is only necessary to turn on the gas and press a button in order to start the headlights—a decided convenience on blustery and rainy nights. The only apparatus involved is shown in the accompanying illustrations—a jump spark igniter to be placed on the acetylene burner and a flexible cable leading back to the dash or other

DETAILS OF THE AUTO-LIGHT.

convenient place where the push button is located; the rest is merely a matter of making the proper connections.

A Quarterly Calendar.—From the Winton Motor Carriage Company, Cleveland, is to hand a quarterly hanging calendar, well designed and produced, showing the various types of Winton machines from the early days of 1896 to the present date.

THE AUTOMOBILE

HOW NAZZARO WON THE TARGA FLORIO

PALERMO, April 25.—Italy is victorious. Of the first ten cars to finish this hard-fought fight seven are Italian and three French. First, second and third positions have been secured by the newcomers to automobiling; France takes fourth, sixth and tenth positions. Nazarro on a Fiat is the victor, at an average speed of 33.45 miles an hour, with Lancia on the same make of machine twelve minutes later and Fabry's Itala in third position.

that test the most powerful brakes. It is the thousand-bend course, for of the 92.47 miles forming the circuit there is only one stretch that can lay claim to be a straightaway run, and there are portions of the circuit where the road winds about on itself in the most intricate and perplexing manner. Three times round gives a total distance of 277.4 miles.

Opel, on an Opel machine, followed the leader; Wagner was

NAZZARO ON HIS VICTORIOUS FIAT PASSING THROUGH PETRALIA SOTTANI ON WILD SICILIAN COURSE.

After three or four days of rain the morning opened with a bright sky and gentle Sicilian breezes which wafted the aroma of citron and orange trees from the distance. Exactly at 5 o'clock Salvioni, an Italian piloting a French Pilain stripped touring machine went over the line amid the excited chattering of an Italian crowd encouraged by a cheer from the strong Franco element. Three times round a mountainous course, starting from the level of the sea and mounting up to giddy heights over one thousand meters above, with grades that stand up like walls, and descents

just behind him, getting away with a rush and a roar, the fastest of the lot. Lancia was about in the middle of the forty-six; Gauderman on a Bayard-Clement had the position that Albert Clement would have occupied had not the military martinets declared that he should not leave his barracks. Hémerly was at the wheel of a Deluca-Daimler, an English-Italian combination. An Isotta-Fraschini, Italian construction, De Dietrich design, closed the list of competitors, forty-six in number.

Hardly had the last machine passed out of sight than the first

WAGNER AT HIGH SPEED PREVIOUS TO BEING PUT OUT OF COMMISSION BY THE SKIDDING OF HIS MACHINE.

to finish the round put in an appearance. It was Opel, followed at an interval of one minute by Wagner, with Trucco and an Isotta-Fraschini on his heels. The Italian had gained one minute on the French champion, but the position was soon lost, for a broken chain put a stop to his wild flight. Trucco made the fastest time of the first round, and as events proved, of the entire course, finishing the initial round in 2:39.8, or more than 34 miles an hour, a splendid performance over such a mountain track. Lancia was only four minutes slower, and Wagner proved the fastest of the Frenchmen.

The outcome of the contest was very undecided at the end of the first round, and excitement increased at the official betting booths. From the outside news came through of accidents and cars broken down on the pitiless course. Salvioni, who set the pace with a Pilain, had finished his course in a ditch, a Berliet had broken an axle, Hieronymus, the German champion, had smashed three wheels, others were out of the race for unknown causes. Thirty-seven finished the first round.

On the second round Wagner made the fastest time and secured second position in the general classification, being only a few minutes behind Nazarro. For a time there was excitement and enthusiasm in the French camp, and just a fear that Lancia, who started 56 minutes behind the Frenchman, might make faster time than the Vanderbilt winner. There was a roar in the distance and Duray rushed by to the delight of the French, followed later by Lancia, who started later, but beat the Dietrich man by less than a minute. When it was possible to calculate the positions, Nazarro with a Fiat was found to be at the head, Wagner was second, Lancia third, Duray fourth and a couple of Italas fifth and sixth.

Wagner Breaks Down After Fast Run.

As the time for the first cars to finish the race drew near, excitement increased. Who would finish first, and would the first to finish be the victor? During the height of the clamor news went abroad that Wagner had abandoned. It was only too true, and instead of the light Darracq it was the heavy Dietrich with Duray at the wheel which was first to finish the course. French cheers had not died away when Lancia rushed up with a shorter elapsed time than Duray, followed a second later by Garcet on a Bayard-Clement. There only remained Nazarro and Fabry, the Fiat and Itala drivers, who could possibly beat Lancia, and in any case the Italian victory was secure. Thirty-nine minutes after Lancia finished his course, Nazarro rushed to the finishing line. He had started fifty-one minutes after him and was consequently the victor by twelve minutes. The strenuous nature of the contest is seen from a comparison of the times for the first ten machines. Between the arrival of Nazarro's Fiat and Garcet's Bayard-Clement in tenth position there is only a difference of 36.6. The first three machines were separated by intervals of twelve and three minutes respectively, and several of the following positions were only decided by seconds.

LANCIA, WHO HELPED TO MAKE FIAT TEAM VICTORIOUS.

Fiat had a most remarkable victory, for Lancia, Nazzaro and Weillschott were all among the first ten. Itala and Lorraine-Dietrich each had two with this select circle. The French, while admitting their defeat, point out that the two Isotta-Fraschini are really French machines being built in Italy under Lorraine-Dietrich designs.

Nazzaro, who in addition to the Targa, will pocket the first prize of \$3,000 in cash, was second in the last Gordon Bennett contest, in which Théry reached the pinnacle of his glory, and was second last year in the French Grand Prix, being beaten then by Szisz on a Renault, but defeating Albert Clement after the most exciting neck-and-neck races ever known. "Now we are ready for the Grand Prix," declare the Italians. "So are we," riposte the French.

Official Positions at Finish of the Targa Florio.

HIERONYMUS, A GERMAN VICTIM OF THE PITILESS COURSE.

Mechanical defects put very few machines out of the race, most of those not present at the finish being the victims of accidents due to the wild nature of the course. Wagner, who at the end of the second round appeared a certain winner, was forced to abandon, owing to his car skidding. His companion Hanriot was put out of commission in a similar manner. Both the Berliet machines skidded, smashing their wheels and breaking axles. Garcet, who was terribly fast on his Bayard-Clément, and looked certain for third place at one time, lost this position through a tire tearing off and his carbureter choking with dust.

FABRY AND HIS ITALA ON A ROAD IN THE MOUNTAIN WILDNESS AROUND PETRALIA SOTTANI.

IF THERE WERE NONE OF THE BOTHERSOME WATER-BARS, THE NATIONAL HIGHWAY WOULD BE AN EXCELLENT TOURING ROAD.

WHEN the tourist who has made the trip to the Jamestown Exposition, has seen all the exhibits, been up and down the "war-path," looked over the naval display, and visited the various points of interest around Norfolk, he may find that he has not sufficient time at his disposal to return north by the all-land route via Richmond, Staunton, and the Shenandoah Valley. To those who wish a shorter return route, and yet desire to pay a visit to a historic section where much of the fighting of the Civil War took place, I would like to recommend the route which our party traversed on our recent return from the Exposition.

After much consultation and studying of maps, we decided to take the boat to Baltimore and then proceed westward over the old National Highway to a point where we would strike the main route from the Shenandoah Valley to Hagerstown. Our choice proved a most fortunate one.

There are two lines of boats from Norfolk and Old Point Comfort to Baltimore: the Old Bay Line and the Chesapeake Line. Probably the competition between them explains the comparatively low rates charged—\$8 for carrying the automobile and \$2 per passenger, including stateroom, if my memory serves me correctly. The first named line has the more modern boats, and should probably be given the preference, but travelers should make inquiries as to just what vessel is to sail on any particular date, because the best boats may be diverted for the use of some

excursion. Leaving Norfolk at 6 P.M., and Old Point Comfort an hour later, the boat docks at Baltimore early in the morning.

Baltimore has entirely recovered from the great fire of February, 1903, and the "burned district" is now a solid section of new modern buildings. An hour or two might well be devoted to a ride around the city. Baltimore is called the "Monumental City," and well deserves the name. On the principal parkways there is a monument every block. The supply of national heroes has been long ago exhausted, and the more recent monuments are to individuals so little known that the visitor constantly exclaims, "Who was he?" The Automobile Club of Maryland has very comfortable quarters in the downtown district, and keeps "open house" to visiting A. A. A. tourists at all hours.

There are splendid macadam roads all around Baltimore, and there are no less than five distinct routes to Ellicott City, where the National Highway proper commences. We went in our White steamer by way of Oella, a little hamlet entered by means of as sharp a "Devil's Elbow" as I have ever seen. Just beyond here we saw the place where the first railway construction in this country was undertaken, the same right of way being now a part of the Baltimore & Ohio Railroad. At Ellicott City begins the famous National Highway, which was opened for traffic almost exactly one hundred years ago. The road is now in the hands of a private company, which charges toll, but keeps the road in very

RIDGEVILLE'S EAGLE HOTEL STILL POSSESSES ITS L. A. W. SIGN.

"JONAS ELLICOTT PRODUCED THE BOLD PLAN OF THIS BRIDGE."

HOMES LIKE THESE FREQUENTLY FOUND IN MARYLAND.

good condition, the only ground for criticism being the numerous water-brakes, which, if taken at speed, give both cars and passengers a severe shaking up.

Ridgeville, thirty-four miles from Baltimore and twenty-one miles from Ellicott City, is the first town of any size along the Pike. The Eagle Hotel here has a reputation for serving good meals, and our experience here led us to believe that its fame in this direction is well founded.

Just before reaching Frederick, we saw the famous old stone bottle which marks the approach to a long stone bridge, the age and style of which are best described by this inscription on the bottle:

"Jonas Ellicott first produced the bold plan of this bridge with arches of 65-foot span; built 1808-09."

Two miles further on we entered Frederick where, according to the poet, in the early days of the Civil War:

Up the street came the rebel tread,
Stonewall Jackson riding ahead.
Under his slouched hat left and right
He glanced; the old flag met his sight.
"Halt!"—the dust-browed ranks stood fast
"Fire!"—out blazed the rifle blast.
It shivered the window, pane and sash,
It rent the banner with seam and gash.
Quick as it fell, from the broken staff,
Dame Barbara snatched the silken scarf.

HARPER'S FERRY, BUSY, PICTURESQUE AND HISTORIC.

She leaned far out on the window-sill
And shook it forth with a royal will.
"Shoot if you must this old gray head,
But spare your country's flag," she said.

On the further side of Frederick, the National Highway bends northwestward toward Hagerstown. We had in mind to go by a longer but much more interesting route, and, accordingly, left the highway at this point, and, bearing left into a well-kept toll-road, passed through Jefferson and Petersville, and then over a rough road to Knoxville, sixty-three miles from Baltimore. Here we came out from the hills to the valley of the Potomac river, which we followed for four miles, and then crossed the old iron bridge from Maryland into Harpers Ferry, West Virginia.

Harpers Ferry is at the confluence of the Potomac and Shenandoah rivers, and is a natural strategic point. Here it was that John Brown, in 1859, after his mad attempt to free the slaves, was captured by the National troops. No vestige now remains of the arsenal in which he and his daring band of twenty-one men made their last stand, but a simple monument marks the spot. The arsenal, it should be said, was evacuated and destroyed by the Northern soldiers a week after the firing on Fort Sumter, to prevent the vast stores contained therein from falling into the hands of an advancing body of Confederates. While the arsenal is gone, many of the buildings of the old town date back to antebellum times. There is a distinct fascination about a place

A GLIMPSE OF FREDERICK, WHERE BARBARA FREITCHE WAVED HER FLAG FROM THE ATTIC WINDOW.

ANTIETAM'S BLOODY BATTLEFIELD, WHERE THOUSANDS DIED.

around which cluster so many historic memories, and we left Harper's Ferry with great reluctance. Four miles west, at Halltown station, we turned into the same road which we would have traversed had we returned by way of Richmond and Staunton. At Charlestown we again crossed a bridge over the Potomac back into Maryland, and, after passing through Sharpsburg, crossed

tourist should object to a few miles of bad going after having had more than one hundred miles of macadam.

The valley is finally reached at Fairfield, from which it is but an eight-mile stretch into Gettysburg. The magnificent battlefield there, and the two routes leading to Philadelphia, I have already described in the November 22 issue of *THE AUTOMOBILE*. I should point out, however, that the condition of the pikes is immeasurably better than when we made our trip last November. Considerable work has been done on the roads, including the smoothing out of many of the water-brakes. If the tourist returns to Philadelphia via York, Columbia, Lancaster, and Coatesville, he will find the Colonial Hotel at York, ninety miles from Philadelphia, a most desirable place to spend the night. In the morning it will be well worth his while to drive to the top of Reservoir Hill and have a view of the adjacent counties.

As I pointed out three weeks ago, the distance from Philadelphia to Cape Charles is 240 miles. That from Baltimore to Philadelphia by the route above described is about 250 miles. The tourist who makes this round trip, starting from and ending at Philadelphia, will agree with me, I think, that nowhere else will he find a route of approximately 500 miles which will make such a lasting impression upon his memory, particularly if undertaken while the Jamestown Exposition is in full swing.

Many whose touring has been limited to the New England and Middle Atlantic States have no idea of the wealth of scenic ter-

WHITE STEAMER CLIMBING THE BLUE RIDGE—ROADS NONE TOO GOOD, BUT SCENERY SUPERB, AND TOURIST WELL REWARDED.

the battlefield of Antietam. Here may be seen, on either side of the highway, numerous fine monuments, some in memory of the Blue and some to perpetuate the valor of the Gray.

Another ten miles and we were in Hagerstown, which is the first city of any size we had seen since leaving Baltimore, the distance between the two places being ninety-seven miles. This is the best place for the tourist to spend the night. By no means should he make the trip to Gettysburg, thirty-four miles further north, after nightfall, because the road between Hagerstown and Gettysburg offers no unusual scenic attractions. North of Waynesboro, Pa., it passes over the Blue Ridge, from the summit of which the view is indescribably beautiful. On this ridge there are several great hotels, a number of fine country estates, and one or two hunt clubs of wide reputation. After crossing the main ridge there is a smaller ridge to be crossed, and here will be found the only stretch of bad going on the entire journey. The road is not simply bad—it is fierce. It abounds in "Thank-you-ma'ams," it is deep with mud in wet weather, and is just wide enough for one vehicle. Those who drive gasoline machines, which have no provision for feeding gasoline under pressure should make sure that their tanks are full before starting over this mountain. Otherwise, owing to the steepness of the grade, they may not be able to get gasoline to their carbureters. This stretch of road, however, is thoroughly passable, and no seasoned

ritory farther south. True it is that some effort is required to reach this section, but the indifferent roads between could be much worse, and, as American highways average, the traveling is well within the power of a sturdy car, capable of doing some climbing when occasion demands.

TOLL GATES ARE FREQUENT AND DECIDEDLY ANNOYING.

SESSION OF A. L. A. M. MECHANICAL BRANCH.

HARTFORD, CONN., May 9.—This week the three days' meeting of the Mechanical Branch of the Association of Licensed Automobile Manufacturers is being held in this city. All day yesterday was devoted to a closed session held at the laboratory of Henry Souther, on Capitol avenue, the association's consulting metallurgical expert. Important subjects were taken up, the first being motor valve-timing, with a view to determining the exact point at which the inlet valves should fully open and close in order to obtain the maximum efficiency. This was followed by a series of tests on vanadium steel castings, and the results of the former are said to promise some information of an interesting character regarding this alloyed product. The subjects of detachable rims and the adoption of formulæ for the calculation of horsepower ratings were slated for the afternoon session.

To-day's session of the Mechanical Branch is being held at the Heublein Hotel. The subject is to be a discussion of the various standard cooling and lubricating systems in current use and a comparison of their merits. Upon the conclusion of this, the members will go in a body this afternoon to make their annual inspection of the association's laboratory, together with the new machinery which has been installed for the extensive tests of the metallurgical and physical properties of metals most largely used in automobile construction.

To-morrow (Friday) will be given over to the *annual* run. This will be about seventy-five miles, and the route lies through parts of the State that are distinguished both for their fine roads and their many historical associations. The start will be made at 9 A.M. from the laboratory, the first stretch being through Wethersfield and Rocky Hill to Middletown, about seventeen miles. This will be the first control, and here there will be a general shifting about, so that every engineer will have a chance to ride in the other fellow's car. Haddam is the next point on the route; it is a quaint old town that the march of progress has passed by, and is much the same to-day as it was generations ago. From here the route leads to Goodspeed's ferry, which will be utilized to cross to East Haddam—the lunch control.

The return trip will be up along the east bank of the Connecti-

cut, with the first afternoon control at Cobalt Crossing; other towns passed through being Portland and South Glastonbury, from the last of which the road leads to East Hartford and across the bridge and home. Though most of the roads included in the itinerary are fine macadam stretches there are some back country roads as well, besides one or two stiff hills.

The meetings have been well attended on both days, and it is expected that there will be additional members here to-morrow, bringing the total over sixty, who will be transported in the following cars: two Pope-Hartfords, Knox, Locomobile, two Thomas forties, Royal Tourist, Franklin, Corbin, Oldsmobile, Autocar, Studebaker, Pierce, Thomas Flyer, two Columbias and a Haynes.

COMMERCIAL SHOW TO BE ANNUAL FIXTURE.

Being of the opinion that a sufficient number of manufacturers of commercial vehicles can be secured to make a showing by themselves, the executive committee of the National Association of Automobile Manufacturers, at its meeting last week, decided to inaugurate the first annual national exhibition of commercial vehicles, to be held in conjunction with the regular show of pleasure vehicles at Chicago this year, which will take place during the week of November 30 to December 7, under the auspices of the national association, as usual. It has long been evident that commercial vehicles could not satisfactorily be shown together with pleasure vehicles, and while there has been more or less complaint on this score on the part of the makers of the latter, the number of manufacturers concerned was not sufficient to permit of the remedy now decided upon. There will be but one admission charged to both separate sections of the show, though it is expected that admission to the commercial end will be very largely by invitation, and to that end exhibitors will be liberally supplied with admissions. Those present were: Albert L. Pope, S. T. Davis, Jr., W. T. White, W. R. Innis, C. C. Hildebrand, M. J. Budlong, George W. Bennett and William Mitchell Lewis. R. D. Chapin, E. R. Thomas Motor Company, was elected to membership, vice Ezra Kirk, resigned, and James Joyce, American Locomotive Company, was elected in place of H. F. Ball.

GOING OVER THE ROUTE OF THE A. L. A. M. ENGINEERS' RUN TO BE HELD MAY 10. H. P. MAXIM, CHIEF ENGINEER OF ELECTRIC VEHICLE CO., AND H. I. CLINTON, A. L. A. M., IN 24-H.P. COLUMBIA, NEAR GOODSPEED'S FERRY.

FIRST APPEARANCE OF THE SIX-WHEEL AUTOMOBILE.

NOVEL SIX-WHEEL CHASSIS DESIGNED BY PRATT.

With the present four-wheel construction, automobiles appear to have reached their limit of wheelbase, and if further length is required it appears likely that the six-wheel type, already in use in Europe, will have to be adopted. Charles T. Pratt, president of the Pratt Chuck Works, of Frankfort, N. Y., has designed and secured patents on a vehicle of this nature. The front and intermediate pair of wheels are steerable, the intermediate pair turning in a lesser angle than the leading pair, power being supplied from a 75-horsepower gasoline engine to the rear pair of wheels only through the medium of an ordinary transmission gear and two-part rear axle shaft. The truck frame is so flexible that any of the four rear wheels may be raised or lowered to a considerable degree without reference to the others and without binding the driving mechanism or straining the frame. An advantage of the machine is that the additional pair of wheels prevents skidding and the two pairs of steering wheels also afford a much better control in directing the course of the vehicle. The car has a wheelbase of fourteen feet, one of the longest ever made, and is built to carry seven people, though additional seats may be added as desired.

ABOUT THE THOMAS MOTOR CAB.

The E. R. Thomas Motor Company, of Buffalo, motor cabs and town cars, have a four-cylinder, water-cooled motor, three speeds forward and reverse, selective transmission, and a shaft drive. The weight of the car is slightly over 1,500 pounds, and the wheels and tires are larger than have been used on cars of this weight or for this purpose before. The designs for these cars were worked out by Gustave Chedru, head of the foreign designing department of the company, who has made a careful and exhaustive study of the cab business in France, and who has designed the cab to embrace the qualities of the French article, with the different essentials incident to the requirements of the American public.

As soon as the plans were completed, months ago, it was found that a separate plant and special machinery would be necessary for the making of this class of cars. Deliveries of these cars will be made early in the fall.

THOMAS MOTOR CAB, THE LATEST THOMAS PRODUCTION.

BOSTON'S SHOW TO BE FOR AUTOS ONLY.

Boston, May 5.—The Boston Automobile Dealers' Association has at last taken the bull by the horns, so to speak, and has absolutely divorced the boat interests from its annual show. Practically ever since automobile shows began in this section the boat makers and the automobile manufacturers have exhibited side by side. But the automobile business has grown by such leaps and bounds and the boat business has increased so rapidly that for the past few years it has been absolutely impossible for all parties that wished to secure space in the Mechanics Building, the largest show building in New England. For some years past, therefore, it has been necessary to hold overflow shows in other buildings, and these have been anything but satisfactory to the management or to the exhibitors. When the show was held last March it became very plain that something radical would have to be done next year. The result was the decision of the Dealers' Association at a recent meeting to admit only automobiles and accessories to their annual show, and the concurrent decision of the New England Engine and Boat Association, backed by the National Association of Engine and Boat Manufacturers, to hold a show of its own in Mechanics Building the week beginning January 27, 1908. The automobile show will be held as usual in the middle of March, and Chester I. Campbell will manage both exhibitions.

Besides the general congested condition of the past shows, the situation as regards space was aggravated by the recent action of the Motor and Accessories Manufacturers' Association in deciding to exhibit in Boston next year. This association cut out the Boston show last March and some of its members thought it was a mistake. Therefore next spring all the accessories makers will be represented and they have already taken 10,000 square feet of exhibition space. This will give room for the display of new novelties, of which New England produces many.

CHINA AS AN AUTOMOBILE MARKET.

United States Consul Wilbur T. Gracey, writing from Tsingtau, states that there appears to be an excellent opportunity for the introduction of automobiles into the colony of Kiachow, his report reading:

There are at present only one American and two German machines in this city, but there is no reason why automobiles could not be used here to a large extent. The roads throughout the colony are excellent, being made through solid rock in many places, and all well macadamized. They run for a distance of 30 or 40 miles into the surrounding country, and with the gradual slope of the hills, about 15° to 20°, would be excellent for automobiles.

I believe that a cheap grade of automobiles could be introduced here for general use. They must be made to compete with the carriages which are now in use. Ponies can be purchased here for about \$40 to \$50 each, are used in pairs, and can be kept at about \$7 per month for feed and \$7 for a hostler. Carriages are either open Victorias, closed broughams, or dog carts, and cost, respectively, about \$350, \$400, and \$100. Small automobiles which are good hill climbers might be introduced if they could be supplied at a low price. Gasoline can be purchased at about 10 cents per gallon, and arrangements could be made for a lower price if there was a call for larger quantities.

The best way to introduce automobiles would be to ship a small number to some local firm to be sold on commission. It would be difficult to introduce machines here through catalogues. If the automobile manufacturers in the United States will forward copies of their catalogues to this consulate this office will retain one copy and pass the others to parties who may be interested. In quoting prices the machine should be given complete, with lamps and all necessary adjuncts. Some of the German firms quote their goods not only complete in every detail, but including extra parts which are liable to wear quickly, such as tires, etc. It must be remembered that American machines must compete with low-priced German goods. There are a good number of motorcycles in use in this city, and there would undoubtedly be a good sale for cheap machines of this kind. In both automobiles and motorcycles one of the most important points to be considered is that the purchaser is three months distant from the United States, and in the event of the breaking of any part of his machine it will be laid up for several months before he can secure new parts. Simplicity of construction is therefore important. Some local dealer should be well supplied with extra parts.

work with critical eye, modifying, improving and changing until both are satisfied. A working draft follows, and when this and the patterns are completed structural work is commenced. With very few exceptions, all high-class closed bodies are built up of wood and aluminum strengthened with iron stays. An open touring body is, with the exception of the frame and the stiffening irons, built up wholly of aluminum. Practice, of course, varies in different factories, but we are dealing with the method followed in the Locke works as descriptive of the highest development

in the modern art of automobile body building.

THERE are two kinds of automobile bodies, the ready-made and the made to measure, the difference between them being precisely that existing between the clothing store product and the article with which the sartorial expert covers your nakedness and hides your natural defects.

The man who lays down ten thousand dollars for a machine is in a position to pay the necessary quota to obtain the elegance and material comfort of which his automobile is worthy, and indeed modern tendency is towards greater elegance and more comfort in automobile bodies.

As can be readily imagined, the building of the highest class of automobile body demands the finest of materials, considerable skill and experience, and is not a task that can be rushed through in a few days. To form an idea of the nature of the work, to watch the up-building of the best bodies on the best chassis, and follow through all the processes from the day the bare machine enters the works to the moment it comes out in the glory of its graceful curves, its well-designed body, its convenient fittings and its mirror-like finish, one must spend a few hours wandering around the works of a reputable body builder.

At 218 and 220 West Eighty-fourth street, a few yards from Broadway, a large proportion of New York's automobile body-work is turned out under the signature of Locke & Co. Incidentally the six-story factory generally contains an assortment of the latest models of foreign chassis awaiting their upper half, only equaled in importance by the annual shows.

Stages in the Growth of a Body.

The high-grade body, such as would grace a Fiat, a Mercedes, or other "de luxe" chassis, is put in hand weeks before the chassis makes its appearance at the carriage works. Frequently, indeed, a closed body begins its growth before the chassis for which it is intended has left its native land. The necessity for this will be obvious when it is learned that the best closed bodies require three to four months to build.

The first stage in the body construction is a full size drawing on a blackboard, made to fit and harmonize with the chassis from blue prints of the latter. Customer and designer examine the

Making a Combination Wood and Metal Body.

For the frame work ash is generally employed. It combines strength and flexibility in desired proportions; it is nearly as strong as oak, without having the brittleness and unbending nature which is that wood's chief defect; it is stronger than hickory without having the excessive springiness of that wood. A machine which is constantly subjected to shocks must be constructed of materials of the very best quality and of such a nature as to combine strength with a certain amount of flexibility. For such panels as are not filled in with aluminum, what is known in the trade as white wood is employed. The varied parts forming the frame having been cut out according to patterns, they are assembled on a pair of trestles and form a skeleton body. There are big gaps between the wooden ribs which must be filled in. Sheet aluminum, about one-sixteenth of an inch thick, is the material employed. It would be almost impossible to accommodate wood to the curves of a stylish automobile body. Sheets of aluminum, cut out to pattern, can be made to fit the most difficult bends by judiciously beating with a hammer on the inside of the curves. Each plate is screwed down to the frame and its edges hidden by a beading of aluminum securely fastened in position, the heads of the nails being filed down so that nothing mars the smoothness of the finish, nor is any joint visible. The illustrations show a number of bodies in course of construction, some of which are in the skeleton stage, while others have been given their sheathing of aluminum.

A rough coat of paint and the body is sent down to the blacksmith's shop in the lower depths, where it is strengthened and bound with metal stays. The amount of strengthening and the position of the stays depends entirely on the nature of the body, whether it is open or closed, whether it will carry a hood or be uncovered, and finally the type of hood used.

How the Upholsterers Make a Transformation.

Up-stairs it travels, to the well-lighted paint shop under the roof, where the preliminary filling coats are applied, coming

WOOD AND ALUMINUM BODY UNDER CONSTRUCTION.

TOURING BODY AWAITING ITS METAL STAYS.

WHERE THE UPHOLSTERY IS PREPARED.

FITTING A SUIT OF CLOTHES TO A FIAT.

down a few days later to be transformed by the upholsterers. Preparations have been made for its arrival, much of the upholstery is already mounted on canvas stretched on large wood frames. One of these is shown in the illustration and is the upholstery for the rear seats of a big touring body. The canvas is cut out of its frame and the complete piece fitted in position on the car. The finest quality of curled hair is used in this work, the covering being either hand buffed leather or various kinds of cloth, according to the nature of the car for which it is intended. Operating as carefully and as critically as a Worth dressmaker, the upholsterer fits the leather or cloth panels, upholsters arm-rests and various parts for which material cannot be made in advance, transforming the bare wood body into a luxurious, well-padded interior, pleasing to the eye and restful to the body.

By this time the chassis will probably have arrived. It is at once sent up to join its companion; the two are bolted together, and any modifications in detail which may seem necessary in order to obtain perfect harmony are here attended to. Now the painter comes on the scene. Filling stuff, rough coats, color coats, succeed one another in quick succession, each one being rubbed down until the previous coat shows through. Altogether a high-class body receives anything from seventeen to twenty coats of paint. The average is eighteen, but the exact number depends on how the finish comes out. If when the final operations are arrived at the body has not a glossy finish to suit the critical foreman, it is passed over and rubbed down again, until

the surface is as smooth as glass. Last of all the varnishing coats are given. A specially prepared room, with double floors, walls and roof, having varnished paper between them, is reserved for this delicate process. Automobile and workmen are left together in perfect stillness, no one being allowed to go near them and not a sound being uttered or an unnecessary movement made.

Finishing Touches to an Elegant Toilette.

Although practically finished when the machine leaves the varnishing shop, there still remain a number of small attentions which give a finishing touch to the creation. Mudguards and other fittings have been prepared and assembled as the work on the machine advanced, and are fixed at the last moment.

Even now the work is not terminated, for every self-respecting body must have a suit of clothes, a suit made of waterproof material, cut and fitted on the body itself. It is the only way to get a good fit; the workman operates with scissors and needle, cutting out here, taking in a stitch there, in much the same manner as a conscientious tailor would operate upon his clients, could he find any with sufficient patience to submit to such treatment.

Ninety-five per cent. of the work in the Locke & Co. factory is for automobiles. Here and there a horse carriage is being built side by side with an automobile body, and some rather instructive contrasts are formed by the juxtaposition of horse buggies of doubtful age with a coterie of automobile bodies of the first blood. There is a large amount of work, too, on retouching and repainting cars.

A GENERAL VIEW IN THE PAINT SHOP, WHERE EACH AUTOMOBILE RECEIVES TWENTY COATS.

HORSEPOWER IN RELATION TO MOTOR DIMENSIONS*

By F. W. LANCHESTER.

WHEN we discuss relative importance of bore and stroke as determining the h.p. of an engine, we have to consider the question of engine speed as limited by inertia and the strength of the materials employed. We may either suppose the maximum to be reached when the material is stressed up to its elastic limit by the inertia of the reciprocating parts, or at some stated point short of this extreme. In any case, the first step in the solution of the problem is the determination of the mass of the reciprocating parts in terms of the bore and stroke, in order that the conditions of σ (stress) = constant may be ascertained.

It is evident that to support a given pressure the piston end will require to be of a thickness proportional to its diameter; this applies whether the form is flat, or conical, or whatever its shape; its mass will therefore vary as D^3 . The piston ring, with its containing "junk" is also a part that evidently should preserve its geometrical proportion; its mass is, in any case, independent of the stroke, and therefore varies as D^2 . The small and large ends of the connecting rod are also unaffected by the stroke, and their linear dimension requires to increase directly as D ; the same applies to the gudgeon pin and the lugs and belt of metal, by which the connecting rod stresses are taken by the piston; the mass of all these parts, therefore, varies as D^3 . The only remaining portions are: the shank of the rod, which evidently varies as $D^2 \cdot S$; and the "shell" of the piston, which is a rather doubtful quantity. If we assume that the length of the piston varies in the direct ratio of its diameter, then this also falls into line with the majority, and varies as D^3 ; this probably is not exactly true, but very nearly so.

We thus have the shank portion of the rod varying as $D^2 \cdot S$, and the remainder of the major reciprocating parts as D^3 , and as the shank only constitutes about .15 of the total mass, I propose to ignore the exception and take the mass of the reciprocating parts as a function of D only, and as proportional to D^3 . The error will be small, and such as it is it will favor the long stroke.

Let R = revolutions per second, then:—

$$\text{H.P.} \propto D^3 \cdot S \cdot R, \tag{3}$$

and maximum inertia force $\propto m \cdot R^2 \cdot S$; but this force is sustained by an area (the area of the rod), which varies as D^2

or stress varies as $\frac{m R^2 S}{D^2}$, but m varies as D^3 , so that stress

varies as $D \cdot R^2 \cdot S$, which, by the conditions, is constant. We can thus eliminate R in h.p. quotation (3) by dividing by the square root of the constant $D \cdot R^2 \cdot S$, and we get:

$$\begin{aligned} \text{H.P. varies as } & \frac{D^3 \cdot S}{\sqrt{D} \cdot \sqrt{S}} \\ \text{or, H.P.} = & c \cdot D^{2.5} \cdot S^{.5} \text{ or, } c \cdot D^2 \cdot \sqrt{D} \cdot \sqrt{S} \end{aligned} \tag{4}$$

where c is a constant.

In order to show the possible magnitude of error introduced by the neglect of the shank of the connecting rod, I have also worked the above calculation on the basis of m varies as $D^2 \cdot S^2$, which seems a sufficiently liberal allowance; we have:

$$\begin{aligned} \text{Stress varies as } & D \cdot R^2 \cdot S^{1.5} \\ \text{H.P. varies as } & \frac{D^3 \cdot S}{D \cdot S^{1.5}} = D^{2.5} \cdot S^{.5} \end{aligned}$$

so the influence of our assumption is not, at most, very serious. As a rating rule I should feel disposed to support any values lying between $n=1.5$ and $n=1.6$ in the L^2 law of § 5. Any value

*Paper read before The Institution of Automobile Engineers, London. Continued from page 742, issue of May 2.

between these limits would not leave much opening for a "special design." For the further purposes of the present paper I employ the form $D^{1.5} \cdot S^{.5}$.

Conditions of Least Weight.

It is evident that for any given type of design, there must be some particular proportion of stroke to diameter appropriate to the condition of *least weight*. By the term *type of design*, as here used, it is intended to convey the condition that, in different engines, the arrangement and function of the parts is identical, the parts compared each to each are situated in the same relation to each other, and are alike functionally.

The *proportion of least weight* may be different in engines designed on different plans; for instance, one engine with an open and another with a closed crank chamber; it may also be different where different materials are used for like parts of different density or thickness.

In order to determine the proportion of least weight for any given type, a trial design is first made, preferably about the proportions that are known to be near the mark. This design is then dissected into its functional components after the manner in which we treated the piston and connecting rod, and the weight of each component is separately considered as a variable, and expressed as a function of D and S . The results are then classified, all functions of like indices being lumped together, and the total weight calculated from the trial design is added up under each heading.

Either D or S is then eliminated (preferably the latter), by dividing by the appropriate power of the h.p. factor $D^{1.5} \cdot S^{.5}$, which is, of course, constant, and so we have the weights of the different functional components expressed as functions of D alone, the total weight being the sum of the expression.

The next step is to differentiate in respect of D , and solve the resulting expression in the usual manner for zero value; the value of D so obtained will be the value appropriate to *least weight*. The corresponding value of S will then be obtained from the constant $D^{1.5} \cdot S^{.5}$. The final design for least weight can then be made.

Influence of Density and Stress on H.P. Developed.

We will now revert to the general expression (1) of § 4—

$$\text{H.P.} = \frac{\sigma^{1.5}}{\rho^{.5}} \cdot l^2 \times \text{constant} \text{—and discuss the influence of changes}$$

in the physical attributes of the materials employed; *i.e.*, variations of σ and ρ .

Translated into ordinary language the expression (1) shows:

That in similarly-designed engines, the h.p. varies as the 1.5th power; that is, as the cube of the square root of the stress, and as the square root of the density of the materials employed.

Now it is evident that the weight of the engine also will depend upon the variables p and l , and for the conditions of geometrical similarity the form of this expression is $W = p \cdot l^3 \times \text{constant}$; (5) so that the h.p. per unit weight, which is the quantity which is

H.P. of most interest to us— $\frac{\text{H.P.}}{W}$ —will be:

$$\frac{\sigma^{1.5} \cdot l^2}{\rho^{.5} \times p \cdot l^3} \times \frac{\left(\frac{\sigma}{\rho}\right)^{1.5}}{l} (\times \text{constant}).$$

Let us denote the quantity $\frac{\sigma}{\rho}$ by the symbol O , and term it

the "specific strength" of the material; then we have:

$$\frac{\text{H.P.}}{W} = \frac{\phi^{1.5}}{l}$$

We have now the question of weight-saving in a nut-shell. The above expression shows that to which I have already drawn your attention—the importance of sub-dividing the power unit by employing a multiplicity of cylinders of individually small size, for we have the *h.p. per unit weight inversely as the linear dimension*, the latter, *l*, being the denominator in the above expression. We can also see at once the importance of employing materials of high *specific strength*; the form of the expression shows that if we can, by employing *all round* a higher grade of material, say of 10 per cent. greater specific strength, we shall effect a saving of weight of approximately 15 per cent.

Of course, it is not always possible to effect an improvement in the quality of the material in every part of a machine, and it is of considerable interest to us to ascertain where and how the saving in weight is most usefully effected.

Weight Saving Considered in Detail.

Let us, to fix our ideas, suppose that we have at our command two kinds of material, one of which has just four times the *specific strength* of the other; and let two carefully-designed engines be built to the same specification, one from each kind of material. Now it is evident that, part for part, the one engine can be built one-fourth the weight of the other. There may be some slight difficulties in design, owing to the slenderness of some of the parts, but we can brush this difficulty to one side by supposing the difference of *specific strength* to be wholly due to a 4 : 1 *difference of density*; that is, σ remains constant.

$$\text{H.P.}$$

So far we have accounted for the $\frac{\text{H.P.}}{W}$ varying in the direct

ratio of ρ only; but the one engine will not only be lighter than the other, but it will develop more power, for its reciprocating parts will give rise to less inertia and the revolution speed can be increased. The extent to which the revolution speed can be increased is in the inverse ratio of the square root of the weight of the parts, or in the case in point, the revolution speed can be doubled. Thus, the h.p. of the lighter engine will become

$$\frac{\text{H.P.}}{W}$$

twice as great as the heavier one, or its $\frac{\text{H.P.}}{W}$ will be 4×2 ; that

is, eight times as great, which is $4^{1.5}$ in accordance with the equation.

We thus see that on the former supposition of a 10 per cent. improvement in the material, producing (approximately) a 15 per cent. improvement in the power-weight factor, 10 per cent. of this improvement is due to the direct lightening of the engine and 5 per cent. to the increased power derived from the higher revolution speed rendered possible.

It is thus evident that by far the greater importance attaches, relatively speaking, to the quality of the material employed in the pistons and connecting rods, for these reciprocating parts do not usually exceed 10 per cent. of the total weight of the engine and attention given to this 10 per cent. is of as much effect as similar attention devoted to any other 50 per cent. of the engine. It is thus found advantageous to adopt the very highest class of material for pistons and connecting rods. For some years past I have employed a high grade of nickel steel, both for the connecting rod stampings and for the blanks from which the pistons are turned, and I believe that the results would justify even more attention still, being paid to the reduction of weight in these organs.

A Secondary Effect.

There is a secondary effect which must not be lost sight of, and which results in a saving of weight which is not obvious from a mere inspection of equation (6).

We have seen that the change in the power-weight factor, as due to $\phi^{1.5}$, takes the form of a saving of weight in the direct ratio of ϕ , and in an increase of power in the relation $\phi^{1.5}$. But we may not want increased power; it is usually some stated power that is required, so that by equation (1) l^2 will require

to vary inversely as $\phi^{1.5}$; that is, $l \propto \frac{1}{\phi^{.25}}$, substituting in equation (6) we have:

$$\frac{\text{H.P.}}{W} \propto \phi^{1.75}$$

under the conditions of stated h.p.; that is to say, h.p. = constant. This may be alternatively expressed by saying that for a given h.p. (for an engine of given number of cylinders), the weight varies *inversely*, as $\phi^{1.75}$.

The equation (1) may be written in the form:

$$\text{H.P.} = \sigma \cdot \phi^{1.5} \cdot l^3 \times \text{constant.} \tag{7}$$

In this form the σ relates to the stress in the working fluid; that is, the cylinder pressure; taking this as constant we have h.p. varies as $\phi^{1.5} l^3$, and when h.p. is constant, we have $\phi^{1.5} l^3 =$

constant, or, $l \propto \frac{1}{\phi^{.25}}$, which, substituted in equation (6),

gives the same result as before; *i.e.*, $W \propto \frac{1}{\phi^{1.75}}$.

We thus see that the saving of weight, to be effected by employing high-grade material, is even more than we had hitherto concluded, so that a 10 per cent. higher specific strength would give about 17.5 per cent., instead of 15 per cent., as previously concluded. The earlier figure was perfectly correct so long as the linear dimension is the constant, instead of the h.p.

Conditions of Least Weight—Continued.

The present method of investigating the proportions of *least weight* is comprehensive, and includes such appurtenances as ignition mechanism, fly-wheel, etc., and may even be extended to include the whole power transmission and change speed gear.

Under these circumstances, it is evident that there are certain factors that may be ignored as being independent of the variables *D* and *S*; for example, the ignition organs, the valve heads, portions of the valve boxes, etc.; that is, (a) parts that are *essentially constant* (example, *sparking plugs*), and (b) parts that are constant in respect of h.p.; that is, vary as $D \sqrt{D} \sqrt{S}$ (example, *valve heads*), and which consequently would vanish automatically in the process of calculation. As a general rule, in practice the whole of the valve and ignition gear may be thrown out at the start, though there may be exceptional cases in which parts of the valve gear must be taken into account.

(To be concluded.)

SOME OF THE USES OF ANTIMONY.

Antimony is a white metal which fuses at a low temperature and is readily vaporized, says the *Canadian Engineer*. It is of a laminated or crystalline texture and is very brittle. It is used in several valuable alloys, but is not used in the pure state; its most important alloys are type metal, britannia metal, pewter and various anti-friction metals. Type metal consists essentially of lead and antimony, with, frequently, the addition of tin, nickel or copper in small quantities. Britannia is a white-metal alloy much used for tableware, and consists of antimony, with tin, copper and bismuth. A similar alloy, containing, however, a smaller percentage of antimony, is pewter. The anti-friction alloys usually are known as babbitt metals. One of them consists of thirty parts of tin to five antimony and one of bismuth, but as is well known, various proportions are employed. Antimony has a hardening effect when added to lead; a small quantity of bismuth gives the alloy the property of expanding at the instant at which it solidifies, the result being a perfect cast from the mold.

TYPES OF AUTOMOBILE TRANSMISSIONS*

By E. H. BELDEN.

AT the outset it will be necessary to give some definition of transmission, which is one of the most improperly applied words in connection with the automobile industry. It is understood to mean, generally, change-speed gearing. In other words, the change of ratio and direction of motion between the rear wheels and motor, but that mechanism is only one element in the train of devices, which transmits the power of the motor to the road wheels. So, therefore, we will designate the change-speed gearing as the "gear-set," and leave the word transmission with a broader meaning, to apply to the entire moving mechanism between the motor shaft and the road wheels.

The available energy, at the road wheels of the automobile, is transmitted from the engine through what is commonly known as a "transmission or gear set." The gear set may be one of many types, but in any case it must perform the office of changing the direction and ratio of motion, between the engine and road wheels, at the option of the operator. Means must be provided for the compensation of the relative motion between the driving axle and frame of the car, to allow for the use of suitable spring suspension, without interference to the uniform transmission of motion. Compensation must also be provided to allow one road wheel to operate independently of the other. Connecting and disconnecting of transmission devices, from the motor, must be accomplished in such a manner that the car may

FIG. 1.—Usual arrangement of double chain drive.

be set in motion without shocks, sudden jerks, or danger of stalling the motor.

Let us now leave out of consideration the advantages or disadvantages of any particular type of "gear set," to which we shall revert later, and take up the advantages and disadvantages of two methods, *i. e.*, the transmission of motion from engine to road wheels by chain and by propeller shaft.

The Double Chain Type.

During the early days of automobile designing it was considered desirable by the majority of the best engineers to use the double chain drive, as shown in Fig. 1. The chain drive was considered to be the more flexible, because the spring action was not deadened by the use of short propeller shaft, as shown in Fig. 2. The speed ratio could be easily changed by changing the size of the sprockets. It was considered to be the more efficient, because of the low efficiency of the bevel gears, when they were forced to transmit the enormous multiplied power of the larger engines. The frame could be hung lower when the double chain drive was used, because the solid rear axle could be dropped the same as the front. In the double chain type of transmission all of the gears, including the bevel, were relieved of the greater strains on account of the ratio of the sprockets.

The principal disadvantages of the chain type are the constant stretching of the chain while the pitch of the sprockets remains the same, producing shocks and noise as the teeth come in con-

tact with the chain rollers; the inability to provide suitable means for protecting the chain and sprockets from dust and mud; the excessive strain on the bearings of the road wheels caused by the pull of the chains, and the deadening effect on the springs caused by the angle of chains and distance rods. There are now being put upon the market three or four types of cars that are provided

FIG. 2.—Power-wasting angle of shaft.

with cases to protect the chains. In each instance the construction of the chain cases are so unmechanical that there can be no doubt but what the propeller shaft will soon antiquate the chain type.

The mere fact that the manufacturers of automobiles, with the double chain drive, are forced to provide their cars with chain casings that cannot possibly prove of advantage to this type of transmission, for the reason that they are only a makeshift, expensive to build, unmechanical, only partially dust-proof and subject to the danger of being totally destroyed every time the chain breaks, is sufficient proof that this type of transmission is far from the ideal.

Propeller Shaft Type.

Now that the trend of automobile designing has been constantly away from the chain types, we must admit that the bevel gears have been perfected, both in material and design, to such a degree that their efficiency and durability is equal to that of the chain type when operated under road conditions. Bevels can be changed to alter the ratio as readily as changing the sprockets and the lengthening or shortening of chains. The matter of lowering the frame has been taken care of by the use of a drop frame, as shown in Figs. 3, 4, 5, instead of a drop axle. The propeller shaft transmission has an advantage over the chain type of being completely enclosed, protected against dust and mud and always well lubricated. This enclosed transmission maintains constant efficiency and is practically noiseless.

The sliding "gear set," as shown in Figs. 6, 7, 8, has an average efficiency of about 78 per cent. The "transmission" efficiency (*i. e.*, the efficiency of all moving mechanism between the motor and wheels, including cardan joints), with the gear set between

FIG. 3.—Shaft drive with gear box on rear axle.

the propeller shaft and motor, as shown in Fig. 2, has an average efficiency of about 67 per cent., while the average transmission efficiency of the more modern car, using the propeller shaft type, with the transmission in the rear axle, with no multiplied power in the cardan joints, is 88 per cent. The transmission efficiency

*Paper read before the Engineers' Society of Western Pennsylvania.

of the "Belden system," with no multiplied power in either the cardan joints or bevel gears, as shown in Fig. 3, is 98 per cent.

After comparing carefully a number of efficiency tests on both the chain and propeller shaft types, we find that the chain type, when the chains are new, clean and well oiled, has about ten per cent. more efficiency than the propeller shaft type when

FIG. 4.—Design of shaft drive for maximum efficiency.

the shaft is placed at a great angle and forced to transmit the multiplied power of the gear set. But comparing the chains on modern cars under ordinary working conditions, with the chains exposed to mud and dust, as they usually are, and the propeller shaft type with the transmission in the rear axle, thereby eliminating the great angle of the shaft and the multiplied power in same, we find the efficiency decidedly in favor of the latter type, as is naturally to be expected under the circumstances.

Power Loss.

Engineers are agreed that the greater part of power loss of the transmission of motion in automobiles is in the propeller

FIG. 5.—The Belden 30-horsepower car.

shaft and cardan joints, due altogether to the friction of the cardan joints when transmitting power at a great angle, as shown in Fig. 2.

Now, considering the fact that bevel gears are inefficient when under excessive strains, we must come to but one conclusion. The automobile of the future will be built on the lines of the car shown in Figs. 3-5, with the motor set back of the front axle. With the motor shaft in line with the rear axle (which will eliminate all loss of power in cardan joints); with large wheels to increase road clearance and decrease road shocks, as well as road resistance; with drop frame for the purpose of keeping the center of gravity low.

With "gear set" placed in the rear axle, for the following reasons:

First. To eliminate the transmitting of the multiplied power of the gear set through the propeller shaft and cardan joints.

Second. To allow sufficient road clearance midway between the front and rear axles, which could not be possible if the gear set is placed under the body, as shown in Fig. 4.

Third. So that the multiplied power will not pass through the bevel gears, but pass through more efficient gears, as arranged in the Belden type of transmission, thereby eliminating the inefficiency of the bevel-gear drive.

(To be continued.)

[EDITOR'S NOTE.—The illustrations referred to under the paragraph captioned Propeller Shaft Type, and denominated as Figs. 6, 7 and 8, picture change-speed gears of the different standard types and were necessarily held over to the second part.

FUEL CONSUMPTION IN MOTOR 'BUSES.

London omnibus companies using gasoline vehicles have discovered to their cost that there is an enormous waste in fuel owing to the inexperience of the drivers they are obliged to employ. A writer in *Le Poids Lourd* says that he has made consumption tests on a number of London 'buses, using a gasoline indicator on the main feed pipe, and is of opinion that one company having 100 vehicles in service has a loss of \$30,000 annually. Certain 'buses of a uniform type, and on the same roads, showed differences in fuel consumption reaching 42 per cent.; drivers in each case were equally capable.

The driver alone on a given car could vary the fuel consumption 25 per cent. per machine kilometer. This shows the need for constantly verifying the fuel consumption for each motor in order to maintain it in the most effective condition. The regulation of the carbureter should always be entrusted to an expert and should never be left for drivers and mechanics to do on the road. Too often the men remedy a loss of power by enlarging the hole in the *gicleur* and some have been known to use the pointed end of a file for this delicate operation.

Every motor 'bus repair shop should be fitted with the necessary instruments for testing not only the power developed but the fuel consumption per horsepower per hour. If these tests were thoroughly carried out every time a motor is dismounted for repairs a great saving would result. Drivers, most of them recruited from the ranks of horse drivers, do not sufficiently understand the mechanism of their machines. The disastrous effects on the consumption when a 'bus is stopped and allowed to run simply with the clutch withdrawn, should be pointed out to them; at such a time the gasoline consumption is higher than if the machine were running at its maximum speed. He should be made to understand that to restart his motor it is not necessary to flood the carbureter until gasoline runs onto the ground. He should be taught to throttle down gradually before stopping so as to have no need to use the brakes harshly. Another important point on which he should be instructed is the effect on the fuel consumption from an abuse of the change speed gear.

Generally motor 'bus drivers travel too fast. Often the last journey is a wild rush through deserted streets, the driver and conductor being only concerned to accomplish the stipulated number of journeys. A system of payment by journeys is better than payment by day, but it has its disadvantages; frequently passengers are left behind who would be able to board the 'bus if it were traveling at a moderate speed. A bonus system on fuel consumption, as is in use by railroad and steamship companies, should be introduced by gasoline omnibus companies. In Paris, where the high price of gasoline renders economy essential, each gasoline cab driver is allowed a fixed sum off his daily takings for fuel. Whatever he can economize by skillful driving is to the driver's personal benefit; naturally if the motor is at fault the driver speedily remedies the matter himself or causes the regulation to be made without delay at the repair shop.

ILLUSTRATING THE WORKING OF A CHAIN.

Hans Renold, Ltd., Manchester, showed at Olympia the latest improvements in silent driving chains, in which the links are not allowed to bear directly on the rivets, but carry removable hardened bushings which turn with the links, says *Engineering*. This arrangement gives to the rivets a bearing the full width of the chain. In order to demonstrate the principle embodied in the construction of these chains, this firm had an electric motor driving by means of a sprocket wheel and chain, an idle chain wheel on one side of the motor, and on the other side of the motor the disks of a stroboscope. The main chain is of the silent pattern. The transverse shaft carrying the stroboscope is fitted at its remote end with an arm bearing an eye-piece on a level with the slots in the disk, the slots being in line with the chain links and the wheel teeth. Viewed through the eye-piece, and when in motion, the teeth and chain appear practically at rest, and the positive contact between the two is shown in a very clear manner.

CONSIDERED IN THE BUYING OF A SECOND-HAND CAR

By CHARLES B. HAYWARD.

IF a locomotive or a marine engine has a useful life of anywhere from ten to twenty-five years before finally being relegated to the scrap heap, why is it that an automobile reaches the same haven of rest in a mere fraction of that time? is a question very commonly asked. Or, to put it in a slightly different form: Why is it not possible to buy a second-hand automobile with the same assurance that any other piece of machinery could be bought in the open market? It is evident that the questioner places the automobile in a special category by itself, and to a large extent this is true; just why it should be so, is another matter entirely.

As a business, dealing in second-hand automobiles sprang up contemporaneously with their entrance into daily life—as soon as there were new automobiles, there were second-hand cars. Probably a man has to be pretty shrewd to sell anything at second-hand and make a living; at any rate, a second-hand dealer is always a second-hand dealer, whether his specialty be old clothes or automobiles. Paint and varnish are cheap, while talk is evanescent and only remembered by the buyer when he discovers his purchase to be something quite different from the glowing account of the salesman—the latter seldom remembers having promised anything of the kind. But how about buying a car that has been used from its original owner?

Many Things to Be Considered.

Of course, all dealers are not dishonest by any means, nor given to making ambiguous statements, such as the automobile equivalent of David Harum's assurance to the clerical buyer of his horse that "he would stand without hitchin'." Whether dealer or individual seller, the statement that the car is "in good condition"—the "best of condition" or its equivalent is bound to be forthcoming. It is utterly meaningless, and may be disregarded, or at least not given any more weight than the grocer's statement when he makes the assurance that the eggs he is selling are "fresh laid"—he may have just laid them on the counter.

No car that has been used one or more seasons can be expected to be in the pink of condition—it is never that way but once, and that is when it is brand new, but given a good foundation to start with and reasonably decent care during its period of use and there is no reason why a secondhand car cannot be considered as an excellent investment. Depreciation is the greatest bugbear of the automobile owner—his new car loses 20 to 25 per cent. of its original value every year; it goes out of style and drops further and further down the price line with the passing of each season. Now this is not actual mechanical depreciation—after two years' use it is practically impossible to sell a car for more than 50 per cent. of its list price, but its actual depreciation with fairly good usage should not exceed 15 per cent., and much of the latter may be remedied by replacement and repair. It is still a good car, and can be had at a comparatively low price, but the buyer of a second-hand car expects to get a good one for next to nothing. There's the rub—alluring prices attract him far more than mechanical soundness. Next to expecting to become the owner of a big car—the second-hand buyer is always looking for the most for his money in the shape of size—the chief cause for dissatisfaction lies in the fact that he expects his purchase to be in a condition to take the road immediately and keep it. It usually does by showing a decided affection for a certain particular spot on the highway where it persists in standing without being hitched.

Slight Defects and Ordinary Wear Immaterial.

Bearing in mind that it is not reasonable to expect to buy a car second-hand that will look or act as if it had just come out of the factory, due allowance must be made for ordinary wear and tear—what may aptly be termed legitimate wear. Mudguards,

headlights and the radiator form excellent indices of the manner in which a car has been used; if it has tried conclusions with sundry obstacles off and on, these parts will reveal it, and they may be taken as an indication that the remainder of the car has not come in for any greater degree of consideration. Naturally there is bound to be a great deal of wear where it cannot possibly be seen—in the motor itself, but the manner in which the latter operates will show whether it is such that a little overhauling will make it good or whether it has damaged to an extent that an outlay for repairs would be money wasted.

Observe the motor closely while it is running with the car standing—it may have an ominous knock in its interior; it may clank, sigh, hiss and groan as it labors, but these signs of infirmity need not necessarily condemn it. A loose big end or piston pin will cause one and leaky, poorly adjusted valves be responsible for the other, while worn out piston rings may account for the fact that the power developed is not all that it should be. Unfortunately, the average seller of a used car is not disposed to let the intending purchaser take it down for inspection, but much can be done by observation of its actions. The interior of the change-speed gear box can be inspected as well as the interior of the bevel-gear drive in case of the shaft-driven car, and the differential in either case. These parts are expensive to replace, and under abuse are short-lived, but with reasonable care are usually good for years of service. The object to be borne in mind throughout the entire inspection is whether, all things considered, the car is in such a shape that a reasonable outlay will render it fit for continued service.

Make a Note of Repairs Needed.

To arrive at this conclusion, a note should be made of every repair and replacement that is needed. It is obvious that a car in which the gears are badly stripped, the differential worn and the motor in need of a number of replacements, is not a good investment even at a very low price. The wheels should be removed and the condition of the bearings noted, and care should be taken to see whether the wheels track or not, as the rear axle unit is an infirmity of many a low-priced shaft-driven car. After a season's use many of them are hopelessly out of true, wasting a large percentage of the power and wearing the tires unevenly, and while the repair required may not be an expensive one, making a good job of it is apt to be so, as the trouble is the result of inherent weakness that is bound to crop out again. It goes without saying, of course, that when the purchase of a used car is in question, only one of a well-known standard make should be considered. Many old cars find their way into the second-hand market for no other reasons than the fact that their owners have purchased others of a later model, but there is also an eternal crop of failures that end up in the same place. They were hopeless at the outset, and no amount of tinkering can better them; they should be avoided as the plague, and particularly because they are frequently offered as "brand new, never run," which, of course, is a fact, but one that should put the buyer on his guard.

In no other field does the ancient maxim of law *caveat emptor* apply with greater force. Let the buyer beware! If the seller gives an absolute warranty that the machine is in a certain condition of fitness, he may be held responsible, but sellers are wise individuals, and much of what the average buyer construes as a warranty is nothing more than mere puffery—the seller's inflated opinion of his own merchandise—and is so considered by the courts. It is just as well to disregard the seller's laudation of his wares *in toto*; the car itself will tell its own story to the experienced eye, and the intending autoist who knows little or nothing about automobiles will find this a roundabout way of saving money unless he goes accompanied by some one who

knows the ins and outs, and is not retained by the other side to sell a car.

Some of the Would-be Buyers' "Don'ts."

Of course there is a whole category of *don'ts* for the man about to purchase an automobile, whether it be new or otherwise, but, like most admonitions, they do not carry a great deal of weight as a rule. There are a few of them, however, that may well be borne in mind, and the first is not to be misled by the appearance of a car. Refinishing its exterior is a far less expensive and far less important item than providing it with new mechanism or other essentials. The car with the shabby appearance gained in a season's legitimate wear is apt to prove far better than the creak of ancient vintage that has been rehabilitated to look like new. Some people are so gullible that a second-hand dealer could sell them a good looking car without any *works* in it at all. It seems to be impossible to avoid referring to the man who makes a living at selling cars that have been discarded by their original owners in discussing the matter of buying such a vehicle, and while on the subject for the moment it may be as well to cite an instance or two of his knavery—only the unembellished facts being given in each case.

For ways that are dark and tricks that are vain, some second-hand automobile dealers have Bret Harte's heathen Chinese "*faded*," to use an expressive bit of vernacular. If the car had existed in the days of the when-is-a-thing-not-a-thing conundrum, the answer to when is an automobile not an automobile? would have been when a second-hand dealer has it for sale. Take instance number one—the misleading for-sale ad. in a daily paper furnished the *come-on* as usual and under the blandishments of the salesman the purchaser became the happy possessor of a car that was guaranteed to be the 30-horsepower model of a well-known maker who failed only a year or so before; in absolutely first-class condition, and good for 30 miles an hour anywhere on the level. The dealer simply hated to take the money for it, so good was the car, but under compulsion was willing to accept about six to eight times what it was worth. The next day the newly-made autoist invited his friends for a ride in his new acquisition, and after getting fifteen miles out at the rate of something nearer three than thirty miles an hour, paid his friends' carfare home and a truckman to tow the car back. Within twenty-four hours later the deluded buyer had found out what any well-informed autoist could have told him before he had been trapped. The car was a model of some four years previous, and had never been anything but a failure. It had a 40-horsepower body and chassis and a 10-horsepower motor to pull it.

The second case was, considerably worse, in that the buyer was a trained machinist, unfamiliar, however, with automobiles. The car was one of the best known of French makes, selling at a high price when new. It was offered at a fraction of its original cost, and guaranteed as having only been run a few thousand miles and as being the model of the year previous. To make a long story short, the car was three years old, and had been abused so that there was scarcely a perfectly sound part in it—which the new owner found out from its original possessor a short time *after* he had parted with his money for it. An electric that was sold as being but a year old and good for thirty miles on a charge, and in good condition, proved to be three years old likewise, with single tube tires that could not be made to hold air, and not good for more than six miles a charge at the most.

The Other Side of the Question.

Instances like the foregoing could be multiplied indefinitely, but there is no necessity for it. They are not cited to discourage the intending buyer of a used car, but simply to put him on his guard, for there is a totally different side to the question, and with the exercise of due care and discretion, considerable money can be saved by investing in a used car. The number of cars of well-known makes that are discarded simply because their owners have become the possessors of others of higher power or later model is legion. A very large proportion of them have been carefully maintained, and even in the condition that they are

offered for sale are capable of immediate running and good service for some time to come. The fact that it will invariably prove more expensive to maintain an old car than a new one must always be taken into consideration, and the question to decide before making the investment is whether the car is in such a condition that the expense of maintenance and repairs is going to prove such as to effectually wipe out any saving that may be made on its initial cost.

It must be remembered that on a used car of whatever make and regardless of its original *quality or standing*, there are always pieces that have seen their best days and will sooner or later need replacement. It depends upon how many things are just about on the point of giving out in a car that will decide whether it is a good investment at second-hand or not. The man who is fond of tinkering and has the facilities and time for the work will be able to take advantage of what would be considered little more than a wreck by the average buyer, who would be unable to get any service out of it except on the payment of an excessive outlay for repairs. Not many autoists are so situated, however, so that this is really an exceptional instance or class of buyer who need not be considered in this category at all.

Figure up as closely as possible what these repairs and replacements are going to cost, and as a much needed factor of safety in such calculations multiply by two. The result should be added to the selling price of the car before its availability is considered. Naturally the seller will be quite positive that either no repairs whatever are needed, or that the car can be *thoroughly overhauled* for a nominal sum, say \$25 or so. Let these things go in one ear and out the other as fast as they will travel, and don't take any stock in the thorough overhauling that is promised. It has been italicised here because it may mean anything from rubbing the outside of the motor off with a piece of waste to cleaning the spark plugs.

To properly overhaul a motor it must be dismantled; transmission ditto, rear-axle unit, steering and running gear likewise; when all these parts have been taken down, carefully inspected after cleaning, due replacements made and carefully adjusted and reassembled, a car can be said to have been overhauled, but it is the better part of a week's job for two good men, or at least one good man and a helper. Not one repair shop in ten would go to this extent in fixing up a car when merely directed to give it a thorough overhauling—it was done earlier in the game, but the customer usually howled long and loud at the size of the bill, so that now such things are only done to special order. It is easy to see that such a job cannot be done for a nominal sum. The thorough overhauling that can be done for a few dollars consists in cleaning things up generally from the *outside*, taking a look at the valves, timer and carbureter and seeing that the motor will run of its own accord for more than five minutes at a time. The size of the repair bill in a case where a genuine thorough overhauling is undertaken depends not alone on the number of hours put in by the two good men, at 60 or 70 cents an hour—and to the man who has to foot the bill they move exasperatingly slow—but also on the replacements that will be needed. Just what these consist of cannot be told until the motor is all in pieces and the condition of its parts is ascertained. New babbitt bearings may have to be poured or new bronzes fitted, new piston rings fitted, new valves, new valve springs, and what not else in the shape of small parts, as well as that of other replacements needed—they all add surprisingly to the bill, but with a fairly good car their cost should be covered by the calculation already referred to.

Given a car of reputable make to begin with and one that has not been unduly abused or that is so old as to have passed the limit of economic usefulness, there is no reason why it should not prove a good investment at second-hand. The buyer must make up his mind to spend at least 10 to 15 per cent. of the purchase price in putting the car in good shape, and unless the car is to be had at a very low price, this appropriation should not include more than one new tire, though it should cover retreading and spare inner tubes.

LETTERS INTERESTING AND INSTRUCTIVE

A Peculiar Case of Smoking and a Remedy Therefor.

Editor THE AUTOMOBILE:

[736.]—Will you please give me some information on the following:

I have a two-cylinder Reo car which makes a great deal of smoke when climbing a grade with the throttle almost wide open, but in traveling level road and when standing it makes no smoke. But when speeding up the motor and then throwing in the gear, it makes entirely too much smoke. Can you suggest a remedy?

Also, my engine misses quite frequently since I had one of the carbureters off to repair a leak. The missing occurs in the cylinder on which I removed the carbureter, but I did not move the adjustment of the carbureter at all. And when on the road it misses oftener with open throttle than otherwise and sometimes will slow down on opening the throttle instead of picking up speed. I discovered that both my carbureters will leak when engine is stopped if the valve under tank is not closed, but when engine is started it stops leaking. Would there be danger of it getting too rich a mixture on that account?

Aukenytown, O.

O. J. WORKMAN.

It would appear that under the conditions first mentioned as the cause of the production of smoke, that the latter comes from the fact that when mounting a grade all the lubricating oil in the crankcase of such an engine runs back into the rear cylinder and burns as long as the car remains in that position, as the rear cylinder will always have an excess supply of oil under such circumstances—or the forward cylinder when things are reversed by going down hill. This would account for the fact that no smoke is produced either on a level road or when standing. Both the foregoing and the fact that it smokes when speeding up the motor would appear to point to an excess supply of oil in the crankcase, and the simplest remedy is to ascertain the proper level and maintain it. Probably the adjustment of the feed cups or oiler has jarred loose somewhat and permits considerable more oil to enter the crankcase than was formerly the case.

Failure of the motor to pick up when the throttle is opened, or actual slowing down under such circumstances, usually point to defective air regulation. It is sometimes the case that when the throttle is opened the auxiliary air-valve remains closed and the mixture becomes so rich that it will not burn, also causing more or less smoke. The fact that the carbureters drip gasoline when the motor is stopped indicates that the float level is too high; the only reason the leak ceases when the engine is running is due to the fact that the gasoline is then being used up faster than it can come through the nozzles. To remedy this the height of the float on its spindle should be altered slightly; the level of the liquid in the float-chamber should be such that it is just slightly below the orifice of the jet. Yes, this would tend to make the mixture too rich at all times, as the gasoline would flow without depending upon the suction of the engine to start it and may account for some of the smoke. See that there is no air leak when the carbureter that was removed is fastened to the cylinder.

Explaining the Acetylene Explosion Mystery.

Editor THE AUTOMOBILE:

[737.]—Mystery of No. 636 is correctly explained by Mr. Covert, Number 703. Accident was caused by explosion of cuprous salt of acetylene, $C_2H_2Cu_2O$. It is a reddish-brown substance, insoluble in water, but decomposes by hydrochloric acid, with the evolution of acetylene. When dry it loses the molecules of water and becomes carbide of copper, C_2Cu , and when dry it explodes violently at $120^\circ F.$, or by friction (see Keyser, Remsen, Newth on Acetylene and Its Compounds). No doubt, if the editor of "The Automobile" would ask Dr. Keyser of Washington University, the authority on acetylene and its compounds, he would be glad to write an article, on either the prevention of the formation of this dangerous explosive in acetylene generators and tanks, or on its safe removal without injury to generating apparatus.

St. Louis, Mo.

E. T. SENSENY, M.D.

Your explanation of the mysterious explosion, set forth in letter No. 636, as well as that of Mr. Covert and others who have shed light on the matter, are of considerable general interest.

Why Are Two-cylinder Vertical Motors Not Used?

Editor THE AUTOMOBILE:

[738.]—Will you kindly tell me through your columns why the two-cylinder upright motor with valves is not used in automobiles. I have seen two-cylinder upright motors without valves, but none with them.

Newman, Cal.

BYRON PACKARD.

To put your question in a slightly different form, it would be: Why are not vertical, two-cylinder, four-cycle motors more generally used? The chief reason is because such an engine is not as well-balanced as a four-cylinder engine, either mechanically or in its impulses. The two-cylinder vertical motors you refer to as being without valves are of the two-cycle type. It just so happens that you have only seen examples of the latter, though, as a matter of fact, there are far more of the four-cycle type in use. However, they are seldom used except for city work, and are coming into demand more and more for this purpose. Hundreds of the gasoline cabs now in service, and more than a thousand that are building or to be put on the market abroad within the next year or two, are equipped with two-cylinder vertical four-cycle engines. They are mainly of French design and construction where motors of this type have been very much favored for light work. In earlier days some of the best known American cars employed the two-cylinder motor, but now there are not many.

Regarding Variable Inlet Valves and Steering Pivots.

Editor THE AUTOMOBILE:

[739.]—In your issue of April 4, "Angelos" inquires on page 587, "What American cars have variable inlet valves?" and you say you do not know of any American cars now on the market so fitted. Duryea vehicles have always been built with the variable lift valve, the valves being suction operated and prevented from lifting by the throttle slide. This arrangement insures the least possible action of the valve with consequent little hammering and noise. This saves destroying the valve and makes them very long lived. I have always used very light valves. A 1-4-inch valve weighs but 3 ounces and is closed by a spring that when the valve is closed has a strength of 8 ounces, and when the valve is opened a strength of 12 ounces. By careful adjusting of these valves each engine can be made to take a charge of such size that it will fire with the same strength as its neighbor, whereas a throttle at the carbureter may not permit such nice regulation. Further, the atmospheric pressure acts against the outside of the valve instead of against the outside of the throttle, some distance from the valve. This means that the engine will take fuller charges if throttled at the inlet valve than if throttled farther away. It is therefore quite essential for suction-operated valves that they also serve as throttles, and when so arranged speeds of 1,200 to 1,500 can be readily obtained, which is enough for long life. Doubtless "Angelos" will submit other reasons.

On the same page is an article on "cambering wheels" and you mention that steering is facilitated "by placing the point of support on the ground under where a prolongation of the steering pivot axis would strike." You do not mention, however, that the best way to get this result is to incline the steering pivot axis so that it strikes under the wheel instead of cambering the wheel so that it strikes under the axis.

CHARLES E. DURYEA.

Reading, Pa.

While for typographical purposes, the heading placed over the letter in question reads "Variable Inlet," the letter itself reads *variable lift*. Though we may be in error in the matter and are open to correction from those better informed on the subject, we have always construed *lift* to apply solely to a mechanically-operated valve, and took it that our inquirer had cars using mechanically-operated valves in mind when he asked the question. On that account we did not include the Duryea car in the category referred to, though had it been in mind at the moment mention would certainly have been made of its exclusive feature in this respect. As you are aware, the automatic type of inlet valve has all but disappeared from the automobile motor, and particularly from American cars, and has not been a usual feature of construction for two or three years past, so that it is not

at all strange that this type was overlooked in making the reply referred to. We are glad to call this exception to our inquirer's attention, particularly as he states therein that he is a strong advocate of the variable lift method of throttling.

We are also glad to call Joseph A. Kimber's attention to your further explanation with regard to the best method of inclining the steering pivot axis, so that it strikes under the wheel instead of cambering the wheel so that it strikes under the axis.

Balancing a Three-Cylinder Air-Cooled Motor.

Editor THE AUTOMOBILE:

[740.]—Being a close and greatly interested follower of the Letters Interesting and Instructive department of "The Automobile," I take this occasion to "butt in," and ask if you will kindly give me a little information.

A friend and myself are contemplating the building of a three-cylinder, 12-horsepower, air-cooled engine, of which we intend to buy the cylinders with the pistons and rings already fitted as well as the valves, also the crankshaft, and are having the aluminum crankcase cast. We realize that we can purchase practically the same engine in complete running order for less than it will cost to build it, but that is not the idea.

The stroke is to be 4.1-2 inches, giving a crank throw of 2.1-4 inches; the crankshaft with plain square web cranks set 120 degrees apart will be supported on four bearings. We are aware that such an engine is self-balancing as a whole, if each of the sections is of the same weight, but what we want to know is whether it will be necessary to attach counter weights to the "heels" of each crank to prevent any tendency toward an endwise "teeter." The engine is intended to be driven at speeds ranging anywhere from 200 to 2,000 r. p. m. You will confer a great favor by answering this question through your columns. H. W. CYRUS.

Astoria, Ore.

Assuming that the weight of each moving unit—i.e., piston, piston pin and connecting rod—in each cylinder be equal, a three-cylinder engine with the cranks set at 120 degrees, such as your design calls for, has an almost perfect mechanical balance, and as in operation a compression stroke in one cylinder will always be opposed to the working stroke of one of the other cylinders, the impulses will also be balanced to a considerable extent. In such an engine it is not necessary to use counter weights on the ends of the crank webs, as is imperative in the case of the single-cylinder type. Nor is it necessary to employ this expedient on either two or four-cylinder vertical engines for automobile or marine use, although an occasional instance will be found.

FUEL AND OTHER CALCULATIONS.

Editor THE AUTOMOBILE:

[741.]—I am enclosing several calculations relating to gasoline vapor as a fuel in the internal combustion motor which I think may be of interest. The basis of these calculations is as follows:

Temperature of hydrogen..... 8,259° C.
Temperature of carbon..... 2,468° C.

When burned in air, in accordance with Bunsen and others, therefore

H equals 3,269 times 9 divided by 5 plus 32 equals 5,898° F.

C equals 2,468 times 9 divided by 6 plus 32 equals 4,466° F. and C₈ H₁₈ equals gasoline equals 6,466° F. equals explosion temperature.

Constants used in these calculations.

Temperature of compressed volume equals 840° F.

Fall in temperature from the moment of explosion until piston descends on power stroke equals 5,466 divided by 3 times 2 equals 3,644° F.

Fall in temperature during power stroke equals 722° F.

Fall in temperature during the compression stroke equals 260° F.

Mean effective temperature equals M.E.T. equals 1,100° F. and 1,100 times 0.002 equals increase in pressure due to heat and M.E.P. equals M.E.T. times 0.002 times CP minus CP plus 14.7, and CP equals absolute compression pressure.

Example:

CP equals 80 times (1,100 times 0.002) equals 176.0 minus (CP plus 14.7) equals 81 equals M.E.P.

in accordance with heat and compression factors, but not including the most radical change that takes place, owing to the proportion that the diameter bears to the stroke. When the diameter is less than the stroke the formula is 176 minus (S minus D times 15) and 13,760 divided by 176 minus (S minus D times 16) equals M.E.P.

When the diameter is greater than the stroke, from a point at

which both the bore and stroke are taken as 3 inches and upward, the formula is: equals 13,760 divided by (176 plus (D minus 8 times 12)); the 175 minus or plus (S minus D times 6) or (D minus S times 2) equals volume per horsepower hour in cubic feet. But for motors in which the dimensions are less than 3D and 2S, the formula changes, owing to the small volumetric charge, as the efficiency is greatly affected by the overcharge of air and as the liquid fuel feed is so small that it can hardly be further controlled. As one volume of the liquid equals 1,740 volumes of the charge, the slightest change in the charge would mean 5 to 50 per cent. decrease in the M.E.P., and in these motors the formula would be: equals 6,466 minus (6,466 divided by 3) minus 612.00 equals M.E.T. and M.E.T. times 0.002 equals constant 2.42. However, small motors vary greatly, the same motor with the same fuel giving different results at different tests, the variation being from 5 to 50 per cent. The most effective motor I ever took a card from had a 6-inch bore by 4.1-2-inch stroke, and showed an M.E.P. of 87 pounds to the square inch.

In my opinion the two-cycle motor is the thing to use, and all these figures refer to it, as I do not consider the four-cycle a scientific production. Nevertheless, you cannot convince the manufacturer; he wants to show a lot of brass and iron for his money.

The following calculation illustrates a method of obtaining the correct volume of vapor from one volume of gasoline.

First calculation:

Gasoline equals C₈H₁₈ at 0.67 specific gravity.

Water at 62° F. equals 62.321 pounds per cubic foot and 62.321 times 0.67 equals 41.755 pounds per cubic foot for gasoline.

Hydrogen equals 0.089523 grams per litre.

Carbon equals 1.07191 grams per litre.

H equals 0.0055912 pounds per cubic foot.

C equals 0.0669442 pounds per cubic foot.

C times 6 plus H times 14 divided by 20 equals 0.0239,971 pounds per cubic foot for gasoline vapor equals 0.024 pounds app. per cubic foot equals C₈H₁₈ equals 0.024 pounds per cubic foot.

41.755 pounds divided by 0.024 equals 1,740 cubic feet of gasoline vapor from one cubic foot of gasoline, which equals 1,740 volumes of gas from one volume of gasoline and one pound divided by 0.024 equals 41,666 or 41.2-3 cubic feet of gas from one pound of gasoline.

Gasoline vapor requires for complete combustion from seven to nine volumes of air. Then 7 plus 9 divided by 2 equals 8 equals one volume of gas to 8 of air.

41.2-3 volumes gas times 8 equals 333.36 cubic feet of air equals total available volume per pound of the gasoline, and volume per horsepower hour equals V.P.H.P.H. and 333.36 divided by V.P.H. P.H. in cubic feet equals pounds of gasoline per horsepower hour consumed.

Calculations to ascertain the B. T. U.:

Formula equals 8,080C plus 34,462 H per Kg in degrees Centigrade.

C equals 6,610 and H equals 28,190 per pound in degrees Fahrenheit.

6,610 times 6 plus 28,190 times 14 divided by 20 equals 21,716 B.T.U. app. per pound of gasoline.

Value of gasoline as a fuel for explosion motors; gasoline at 20 cents per gallon; 7.48 gallons per cubic foot.

7.48 times 20 equals \$1.496 per cubic foot.

\$1.496 divided by 41.755 equals \$0.0358 or 3.58 cents per pound and 0.0358 divided by 333.36 equals \$0.0001076 per cubic foot or 10.75 cents per 1,000 cubic feet of gas, and if 173.7 cubic feet equals one horsepower hour, the cost per horsepower equals 173.7 times 0.0001076 equals \$0.01867 equals 1 cent 8 2-3 mills per horsepower hour.

Gasoline as compared with coal gas:

One pound gasoline vapor equals \$0.03583 equals 41.2-3 cubic feet of gas, then

0.03583 divided by 41.666 equals \$0.00086 per cubic feet of gas, or \$0.86 per 1,000 cubic feet of gas, and it is 25 per cent. less than coal gas, or as 8 is to 6. Then as

Coal gas equals 6 of air equals 6,000 and

Gasoline vapor equals 8 of air equals 8,000 and 2,000 plus air equals 25 per cent. or 0.0001076 times 6,000 equals 64.5 and 0.0001076 times 8,000 equals \$0.86 at \$1 per 1,000 for gas, and \$1 divided by 8 equals \$0.126 and \$1 divided by 6 equals 0.1667 and \$0.1667 minus 25 per cent. equals 0.126 or

Gasoline vapor and air, volume equals 8,000 cost \$0.86.

Coal, gas and air, volume equals 6,000 cost \$0.86.

Gasoline vapor and air volume of 6,000 cost \$0.645.

Gasoline as an economical fuel for test run.

48 divided by hours of run equals power consumed during run for a 26-pound limit, as

Run equals 4 hours and 48 divided by 4 equals 12 horsepower consumed in 4 hours from 25 pounds of gasoline.

48 equals (333.36 times 25 divided by 173.7 or x volume).

x volume equals volume per horsepower hour.

I consider this a just rating for gasoline. R. C. MATLACK, Chicago, Ill.

A THREE-TON TRUCK FROM KANSAS CITY

AFTER a wide experience in all classes of pleasure vehicles, the concentration policy of the Kansas City Motor Car Company, of Kansas City, Mo., has led to the production of a three-ton truck only, a vehicle which benefits from the earlier diversified work of the firm and profits by its present equipment and well-selected international staff. The vehicle has been designed with a full knowl-

AS SEEN WHEN APPROACHING.

edge of the conditions under which the mechanical truck has to work, with the result that simplicity, accessibility and robustness form distinguishing features.

Carried forward on a Bethlehem chrome nickel steel frame, where it is in the most accessible position possible, is the power plant of the truck. The channel section frame is 168 inches long, 7 inches deep, 48 inches wide, narrowed to 36 inches at front to permit

of big steering angle; it is reinforced by five cross members and large gusset plates riveted in pairs. Realizing the importance of a good suspension in the life of tires and engine, special steel springs, ten leaves 40 by 2 1-2 in front and 13 leaves 48 by 2 1-2 in the rear, are provided. The rear springs are double-shackled with extremely stiff distance rods, pivoted on sprocket shaft supports. The front axle is one-piece hammered-forged Krupp special steel, I-beam section, with Elliott-type steering yokes, with one H. B. ball thrust bearing, spring seats being integral. Steering knuckles are very heavy, hammer-forged with two large H. B. ball bearings on spindles. The rear axle also is one-piece hammer-forged Krupp steel, with integral spring seats, and H. B. ball bearings on each sprocket. The position of the motor forward leaves nearly the whole body of the truck avail-

able for the load, actual dimensions being 4 behind the driver's seat. Actual weight of the truck

is four thousand pounds, and full load capacity three tons. Wheel-base is one hundred and fourteen inches, track sixty-four inches and maximum speed is ten miles an hour.

A look through the big inspection plates in the frame forming driver's seat reveals a four-cylinder, four-cycle vertical motor with cylinders cast in pairs, mounted directly on the side frame. Valves are on opposite sides, each camshaft being machined out of the solid with cams integral; compression reliefs are provided for ease in starting. Very large water jackets, with 1 1-4 inch water connections, surround the cylinders; water circulation is assured by a large gear-driven centrifugal pump through a stiff tubular radiator equipped with a belt-driven aluminum fan.

Double ignition is provided by a high-tension magneto and battery and coil. There is fixed sparking point, spark being only retarded automatically when cranking the motor. Control is entirely by throttle lever on top of steering wheel, and by acceler-

REAR VIEW SHOWING DRIVE AND KINDRED MECHANISM.

ator pedal for quick-speed regulation in heavy traffic. The speed of the motor being automatically regulated by the governor to 1,000 revolutions a minute, corresponding to ten miles an hour, and the governor being built foolproof as a part of the motor, nothing is to be feared on this score from the antics of unskilled drivers. The carbureter is of a special design of the double-jet type, water-jacketed, so constructed that one jet only can be used for starting and slow speeds, the other being brought into play for maximum power.

The transmission is of the progressive type, giving three speeds forward and reverse. The aluminum gearcase has three-point suspension. Final drive is from countershaft to sprockets on rear road wheels by double side chains of the Mors silent type. Twenty-two H. B. ball bearings are used.

SIDE ELEVATION OF THE KANSAS CITY THREE-TON TRUCK, SHOWING LOCATION OF MOTOR.

THE GEARLESS TRANSMISSION.

In perfecting the gearless transmission, the constructional details of which are illustrated and described herewith, it would appear that a long step toward the realization of the goal of many a designer—the gearless car—had been taken. Both the shortcomings of the present system in which, with few exceptions, gears are slid into mesh while in motion, as well as the reasons which have worked for its retention, are matters of too common knowledge to need recalling. "Simpler than a planetary, stronger than spur gears, more lasting than either," is a brief condensation of the maker's claims for the gearless transmission which consists of but three parts in all. These are a cup, a cone and a cage holding six rolls, the simplicity of these parts being evident at a glance from the illustrations. All are contained in a single housing, a view of which is shown. This comprises two-thirds of the entire change-speed gear, or rather device, as its chief feature is its lack of gears, in that with its aid, the low and reverse speeds are obtainable. The direct drive is obtained by means of a special clutch encased in a second housing, shown facing the first in the illustration referred to.

From the foregoing it will be noted that the gearless transmission bears considerable resemblance to the well-known planetary type, the similarity being very great so far as outward appearance is concerned, this being evident from the plan view of the chassis showing the complete gear in place, while the method of operation is actually the same. The remaining essen-

SIMPLE ESSENTIALS OF THE GEARLESS TRANSMISSION.

tial of this change-speed device consists of a crab-clutch splined upon the driving shaft and sliding thereon by means of a hand lever. As the forward end of the driven shaft is journaled in the hub of the driving cone, and the latter is permanently attached to the driving shaft, carrying the internal portion of the high-speed clutch, the external portion of the same is rotatable thereon, as is also the cup of the transmission. Thus the high-speed clutch is only connected with the driven shaft of the car when the crab-clutch is shifted so as to engage it, connecting it with the driving shaft from the motor.

The details of the working of the device can most readily be understood from a description of its operation rather than of its parts and their relations. To obtain the first or low-speed forward, the crab-clutch mentioned is shifted forward engaging the cage of rolls forming part of the external portion of the high-speed clutch, thereby connecting it with the driven shaft of the car. The cone keyed permanently to the motor shaft revolves the cage of rolls permanently fixed to the external member of the high-speed clutch by means of studs, in the same direction that it revolves, and as the cup of the transmission is held stationary by one of the brake bands operated by a foot pedal, it will be evident that the cage of rolls must roll around the interior face of the cup. This transmits the power to the driven shaft through the crab-clutch, which is splined on it. For the direct-drive or high-speed, pressing another pedal forces the cone forward, causing its tapering face to engage the roller on the end of the lever, raising the lever and opening the ring of the clutch against the inner side of the periphery of the housing.

From the foregoing, it will be apparent that the crab-clutch mentioned is always in engagement with the cage of rolls for the forward speeds. In order to obtain the reverse speed, the side

lever is called into play to slide this crab-clutch rearward, thus disengaging the external portion of the high-speed clutch from the driven shaft of the car and connecting therewith the external cup of the transmission. As the cone is permanently keyed to the motor shaft, it revolves continuously and thus turns the rolls,

THE TWO CLUTCHES READY TO MOUNT ON CAR.

thereby transmitting power from the cone to the cup through the medium of the rolls, which cause the cup and driving shaft to revolve in the opposite direction, thus giving the car a reverse motion.

The transmission is held in proper adjustment by means of a pressure bar located back of the cup, as shown in the plan view of the chassis, the required tension being maintained by springs exactly as employed in the familiar cone type of clutch. The cup is always in contact with the rolls at the required pressure. To start the car, it is only necessary to depress the pedal corresponding to the low-speed brake band, which compresses it around the cup of the transmission and gets the car under way. As soon as it is moving, this pedal is released and the other depressed, shifting the trunnion cone which operates the high-speed clutch. To shift from high to low-speed is even simpler, as it is merely necessary to depress the first pedal, again tightening the first brake band and automatically withdrawing the trunnion cone from engagement. The emergency brake is also interconnected with this cone and releases it when put on. There is a third pedal, which, when the car is running on either of the forward speeds, acts as a powerful transmission brake, as it compresses the band surrounding the high-speed clutch. The

PLAN VIEW OF CHASSIS SHOWING TRANSMISSION INSTALLED.

drum upon which it acts is 18 1-4 inches in diameter by 2 1-2 inches face, so that it provides a very powerful retarding agent. The gear ratio is 9 to 1 on the low-speed and 3 to 1 on the high-speed, this driving being alterable by changing the size of the pinions. The Gearless Transmission Company, Rochester, N. Y., are the makers.

It seems fitting that the builders of the Darracq cars whose experience has led them throughout the entire range of automobile construction from the single-cylinder car up to the eight and back again, as they are at present devoting attention to a one-lunger, should also specialize on a "six." This is a 50-horsepower shaft-driven car that attracted considerable attention when first uncovered at the Paris Salon last December, and is characterized throughout by features of design and methods of construction that have carried cars of this make to victory in more fields than one. The pressed steel frame forming the foundation of the chassis is of the type long characteristic of this car, all its members being of a deep-flattened "U" section in the model under consideration. There are four cross-stays, all of which are webbed at the corners to reinforce them. A sub-frame construction is employed and is carried on the first, second and third cross members. The side members of the main frame taper each way from the center, where they are six inches wide; they are turned in three inches at the dash in order to give an increased steering radius, and at the forward end of the rear springs they are given a four-inch camber in addition to being narrowed, this construction providing for additional spring play. The first cross member, which also acts as a radiator support, is carried low, so that the bottom of the radiator sets below the level of the main frame; it is placed just to the rear of the front axle. At the other end long S-shaped drop-forged dumb irons are employed to extend the spring length, besides carrying the body on lugs. The groundwork of the chassis is completed by the drip pan, extending from the radiator to the rear of the gear-box.

Motor Design.— The cylinders are cast in pairs and bolted to a comparatively shallow aluminum crankcase, provided with a large handhole opening on the right side. The base is divided into two parts, and a departure has been made in the method of fastening it to the sub-

frame by providing a continuous flange in place of the customary arms or lugs, thus making a much more solid form of construction with practically the same amount of metal. The cylinders measure 112 mm. bore by 120 mm. stroke, all the operating mechanism being placed on the left-hand side of the motor. All the valves are mechanically operated and interchangeable, and the single camshaft is utilized for driving the magneto and the gear pump, as well as operating the valves, while at the end it carries a bevel gear, driving a short vertical shaft carrying a Nieuport auxiliary timer on the dash, as well as the LeFevre mechanical oiler, by means of a Powco wire belt, the complete oiler being placed on the dash. The right-hand side of the motor is totally unencumbered except for the water-intake pipe and three oil feeds, thus permitting a free hand in working at the internal parts of the motor through the openings in this side of the base.

In an engine of the length necessary for six cylinders, it is quite a problem to so dispose the piping as to make it most convenient with the least length. In the case of the exhaust this has been accomplished by the use of two separate exhaust manifolds, each of which takes care of the exhaust from three cylinders, and is piped independently to the muffler, thus providing ample expansion space and rapid cooling. A short branch, made fast to the rear exhaust pipe, is led around the carbureter to provide a supply of hot air for the latter.

One of the most striking features of the motor design is to be found in the webbed construction crankshaft. As will be seen in the illustration showing this essential of the motor, the regulation type cranks or throws have been replaced by solid disks, each of which acts in the capacity of a small flywheel, thus tending to improve the balance of the motor. These disks are 15-16-inch thick and 7, 1-16 inches in diameter; there are nine of them in all.

The crankshaft is sup-

CARBURETER SIDE DARRACQ "SIX" SHOWING INTAKE MANIFOLD.

THE PECULIAR ONE-PIECE DISK-CRANKSHAFT.

ported on two four-inch babbitted bearings at the ends and two three-inch bearings at the center, the latter being placed between the second and third, and fourth and fifth cylinders. The flanged connecting rods are provided with cups to scoop up the oil from the shallow crankcase, while runways are fitted to carry oil to the crankshaft bearings. The camshaft is in one piece with the cams integral, the cylinders firing in the order of 1-4-2-6-3-5. The flywheel is 15 inches in diameter and has a 5-inch face. Cooling is taken care of by a gilled tube radiator and gear-driven pump, supplemented by a fan.

Carburetion.—Quite in contrast with some of the cars that have been on the market as long as the Darracq, the carburetor is of the simplest type, consisting of a float-feed chamber and single nozzle with an auxiliary air inlet controlled by a helical spring. It is always adjusted at the factory to give the best results, and the success that has attended its use on the many cars of this make turned out shows that its factor of reliability is very high, and quite in keeping with its simplicity. The problem of designing an intake from the carburetor to the cylinders that would represent an approximately equal length of tube from the central point to each has been solved in an ingenious manner, as will be plain from the illustration picturing the valve side of the motor. Brass tubing of 1 3/4-inch diameter is used and is of uniform size throughout. The carburetor is centrally placed between the third and fourth cylinders, and the intake attachment to it is in the shape of the customary Y, which turns upon itself after rising a few inches, and is converted into an inverted Y, forming a diamond as shown. The upper Y communicates with the third and fourth cylinders, while the two branches which leave it on either side carry the fuel to the first and second on one hand, and the fifth and six cylinders on the other. With a six-cylinder engine, as the impulses overlap one another, the suction stroke of one-cylinder is not quite completed before that of another begins, which results in exerting a uniform suction on the nozzle.

Ignition Details.—In accordance with current practice on high-grade cars where this essential of the motor is concerned, two independent systems of ignition are employed, both of them being of the high-tension type. One consists of a self-contained unit—a Simms-Bosch high-tension magneto, while the other is a synchronized system employing accumulators as the source of current supply. Though each system is complete in itself the wiring has been simplified and the amount of apparatus reduced to a minimum. The accumulator system consists of a single Nieupert coil mounted on the dash, which also supports the combined timer and distributor driven by bevel gearing from the camshaft. The contact breaker cam is hexagonal and is mounted on the same shaft as the distributor, which has been made as simple as possible. The six terminals representing the plugs

THE REAR AXLE UNIT SHOWING GEARS AND BEARINGS.

from the cylinders are housed in a recessed vulcanite chamber, while a revolving disk of the same material carries the moving connection of the other side of the circuit. As there is very little necessity for advancing or retarding the spark when using the magneto system—and this, of course, is the constant-service system, the battery merely constituting a reserve—no ignition lever is fitted on the steering wheel. Instead, a small lever is carried forward from the magneto, ending in a ring near the starting crank in order to retard the time of firing to start; once under way, the lever is pushed back, and the car is run without altering the time of ignition. A ratchet lever and sector is placed on the dash for advancing and retarding the spark when the battery system is used.

Transmission.—The first step in this essential consists of the conventional type of leather-faced cone clutch, which, however, is not wanting in original features. It is entirely self-contained, both the flywheel and the aluminum cone being carried on the crankshaft of the motor, the retaining spring being housed between the two. To prevent the clutch from taking hold with a jerk in starting, four strips of clock spring-steel press against

CHANGE SPEED GEAR BOX SHOWING PEDAL BRAKE AND SPRAG.

the flywheel rim, and take the pull of the clutch until the latter is firmly engaged, permitting an easy start, even on the high gear. These strips are pressed outward by four small helical springs.

The changespeed gear box provides four speeds forward with the usual *marche arriere*, and is operated on the selective system, the hand lever being provided with a trigger which must be pressed in order to set the lever in the reverse position, the slot corresponding to the latter being fitted with a gate. The countershaft of the changespeed gear is placed beneath the main shaft, instead of parallel, and is idle on the direct drive.

General Details.—Two sets of brakes are fitted and the practice of making the running brake act on some part of the transmission system has been adhered to. This brake is pedal-operated, and consists of a drum placed on the propeller shaft just behind the gear box; it consists of a drum and metal band. Just behind it, on the same shaft, is a ratchet sprag operated by a small lever from the dash. The emergency brake is of the internal expanding type and is located on the driving wheels.

The steering gear is of the worm and segment type, supported on ball bearings, and the steering pillar is given just sufficient rake to place it in the most convenient position for the driver: the steering knuckle is a three-piece drop forging. Semi-elliptic springs are employed for the suspension, the forward pair directly under the frame measuring 37 inches in length, and have eight 1 3/4-inch leaves, while the rear pair is shackled outside the frame, and measure 45 1/2 inches, having nine leaves of the same width. The wheels measure 980 mm. by 120 mm.; they run on two-point ball bearings and are shod with the Michelin racing type of tires having a ridged tread. The gasoline tank, holding 17 gallons, is located under the front seat, and is of seamless brass, bolted directly to the frame. The wheelbase is 132 inches, tread 53 inches, and the clearance 11 1/2 inches. The gear box fitted gives the car speeds of 9, 17, 38 and 60 miles an hour.

Continuing An AUTOMOBILE in OLD PROVENCE Around The ETANG de BERRE

"I HAD rather discover a new road across France than blaze a trail across 'Darkest Africa,'" said the chauffeur; and he was quite right. There's a wealth of novel experience to be had, besides no end of out-of-the-way information to be gathered, if one will only leave the beaten track and strike out for himself anew, not necessarily into a wild unpeopled region, but at any rate off the track of conventional travel. The byroads are not so "fast," as the automobilist puts it, as the high roads, but, like Prince Charlie, one often arrives before the others who stick to the well-worn roads. The shortest distance between two given points is often not by the "Routes Nationales," but by the *routes secondaires*, and even those of the third class, all of which are more than ordinarily good in France when judged by any other standard of road values.

There is a little outlying section of Provence, just off the great highway which runs from Paris to Antibes and known as the Route d'Italie, which Riviera tourists by road or rail know little of. Nîmes, Arles, and Avignon they know, and at times linger in beyond the hour and a half usually devoted to déjeuner, but the vast wind-swept tracts of the Crau and the Camargue, with their olive groves and cypresses and their flocks and herds and their little, sleepy, old-world towns, are a terra incognita to many who would revel in their delights if they only knew.

This, then, is a plea for that part of Provence known as the Bouches du Rhône. It has been shamefully neglected by winter birds of passage to the Riviera and the stale divertissements of Monte Carlo and the bridge parties and the tea-fights of Nice and Cannes.

Between Arles and Marseilles, then—after one has made that delightful excursion to the Gallic Pompeii, Les Baux—is a region full of quaint charm and novelty which the "personally conducted" know nothing of, and which must truly be seen to be appreciated.

Off at a tangent, southeast forty kilometers or a little more, from Arles, is Les Saintes Maries, the landing place in Gaul of the three Marys of Judea, who were "exiled in an open boat without sails or cordage," as the legend has it. The great fortress-

church of the little fishing village of "Les Saintes" is one of the wonder works of architectural art. Within is the shrine containing the relic of the Marys of Judea, and beneath in the crypt is the burial place of the gypsy Sara, their servant, and the *patronne reine* of all the gypsies and vagabonds in Christendom. Here, on the twenty-fourth of May of each year the nomads and *romany chiefs* from all parts of Europe gather to pay their devotions at the shrine of their sainted Sara.

At any time of the year it is a pilgrimage not to be neglected by any who pass by Arles. Go down and back between breakfast and lunch, or between lunch and dinner, or lunch at the Hotel de la Poste at "Les Saintes," if you will; but, anyway, you will have to pick up your wheel-tracks again back as far as Arles, as there is no other way of crossing the Rhône, and taking up your route again towards Marseilles.

Taking the road again from Arles, the route is due east for Salon, forty kilometers straight away over the stony Crau, with a road absolutely level for most of the distance.

Highways Which Are Not of Yesterday.

Here's a good place to consider how and why these first roadways across southern Gaul were made: The Phoceans made the first great thoroughfares in Provence, the *via Héraclea* being the oldest of all which can be traced with certitude. It began in the south of Spain, and freeing the Pyrenees reached the Rhône, near Arles, where it branched out into three arms, one going north by Avignon, another easterly or northeasterly via St. Rémy, Cavaillon and Apt to the Alps, and the other striking across the Crau to the south of the Alpilles, the latter, probably, being the precursor of this very Arles-Salon road, continuing on to the Italian frontier over Les Maures and the Estérel.

The last portion alone—the southern route—is that actually traced by Hercules, but the nomenclature is generally given to the entire trunk-way. None of the villes formerly existing on this *via Héraclea* exist to-day, none dating in fact as settlements of magnitude, before the Roman era.

The Massaliotes reviewed and resurveyed this route and put up the progenitors of the modern mile-stones every eight *stades*, one of which may still be viewed in the Hotel de Ville at Salon.

For forty kilometers one crosses this strange nondescript land, the Crau, peopled only by an occasional lonely Mas or farmhouse and immense herds of sheep, goats and long-horned cattle and their guardians, a sort of a cross between a cowboy of the far West and a Swiss shepherd.

Mostly this vast, vague land, and its neighbor, the Camargue, the other side of the Rhône, is nothing but a grazing-ground, however. The cattle are chiefly a race of Spanish-crossed bovines, the bulls of which are frequently driven wild into town and put through their paces in the old arenas of Arles and Nîmes, or even in an improvised Plaza in the smaller towns, such as St. Rémy or Salon. It is commonly thought that bull-fighting is not a French institution, but be that as it may, there is no question but that it is as much the Provençal's pleasure as it is the Spaniards'.

Salon, the center of the olive and olive-oil trade of France, is an ancient bourg and a modern one; it has a fine old city gate, an ideal old battlemented château, and other relics of days gone by, and it also has cafés that would do justice to Paris, two or more exceedingly up-to-date hotels, and a typewriter agency (American, of course). The Grand Hotel at Salon is an efficient establishment which has a "good-enough" garage, and which caters for the inner man bountifully and excellently, if in somewhat a reminiscent fashion of a *grande ville*.

From Salon to the shores of the Etang de Berre, a great landlocked inland sea, is not more than a dozen kilometers, and one should first make for St. Chamas, there to visit the Pont Flavian, one of the world's bridge-building wonders. The road can easily be missed coming out from Salon, and if you are not careful you will bring up in the ugly, disgusting, little railway junction of Miramas, instead of St. Chamas, which you will not want to do at all if you have the true automobile spirit.

We went first to St. Chamas avowedly for the purpose of seeing the Pont Flavian, which our remnants of memorized history told us existed. We wanted to see it because we wanted to drive our automobile over a Roman bridge, whose foundations were first laid in the reign of the conquering Augustus. One meets with a genuine surprise when he first comes upon the Pont Flavian. It spans the rocky bed of the Touloubre and remains to-day one of the finest of those Roman monuments which were scattered up and down Gaul in the days of the Western Empire.

Skirting the western shore of the Etang de Berre, one arrives, in another dozen or fifteen kilometers, at Istres, a veritable Italian hill-town in France, as quaint and picturesque as anything to be seen in Piedmont. To eat and sleep, one must keep on as far again, when he will find the Père Chabas at Martigues' Grand Hotel ready and waiting for him.

Something of Interest to the Epicure.

One comes to Martigues' for two things, because it is known to the French as the Provençal Venice, and because of Chabas and his *bouillabaise*, the famous plat of Provence, but cooked nowhere with the quintessence of delicacy and aroma as by le Père Chabas, as he is affectionately designated.

As we drew up before Chabas' ever-open welcoming door, a perfume and an incense floated out which brought again to mind

dress of Arles—and runs the finances. As she puts it herself: "Paul he makes the bouillabaise and I keep the purse-strings. otherwise we should be as poor as a Martigaux." (Chabas comes from Cavaillon—the home of all good cooks, and Madame—being an Arlésienne—can afford to talk this way.) From this you may judge what a "good sort" Chabas really is. He knows how to cook baked beans, too, and makes a wonderful concoction which he calls an "*omelette Américaine*," which is nothing at all American, but the most glorious *omelette au rhum* you ever ate, or are ever likely to eat.

Where Modern Industrialism Jostles Antiquity.

Four kilometers from Martigues, at the outer end of the Canal de Caronte, and at the very edge of the surging, shimmering Mediterranean waves, is Port de Bouc, with a great shipbuilding works and a population which is as Italian as it is French, and in some respects more picturesque.

St. Mitre is six or eight kilometers to the westward, and is an old Saracen hill-town, once a stronghold of renown, as its old ruined walls and gates still show. Fos-sur-Mer, hardly known except to antiquarians, is between St. Mitre and the sea, and is the ancient Roman Civitas Marius, a poor, wind-worn relic to-day of a power long since dead and buried. The old walls, or such as remain, are as lively a representation as one may find of a

THE ROADS OF THE BOUCHES DU RHONE.

the days when three American artist folk put in one long, bright winter here and ate *bouillabaise* once a day for a hundred days on end, and didn't get tired of it either. We also ate langouste—as much of an improvement over the lobster as the lobster is an improvement over a crab—and oysters, and even mussels—which no one in America ever thinks of eating, though here we thought them an excellent dish.

There may be many good and sufficient reasons why all automobile tourists cannot find the time to explore all the highways and byways of Provence that he would like, but there is absolutely no excuse for giving Martigues and Chabas, and his *bouillabaise* the go-by. To do so would be doing one's self an injustice, since the route via Martigues, from Arles to Marseilles, is as good a road, and but a trifle, if any, longer than that which is known as "la grande route."

Martigues is known of all Provençaux, by some Frenchmen, and by a few—a very few—outsiders, mostly artists and Americans at that; seldom if ever an Englishman. There are no tea-shops! Martigues is Venice without the palaces and history; its quais and canals are every whit as picturesque as the Guidecca, and nowhere along Mediterranean shores are to be seen so wonderful a collection of those queer lateen-rigged, *tartanes*, *balancelles*, *bêtes* and *catalans* as here. And then there is Chabas again with his cookery which can't be beat by anyone, and equaled by but few. Nothing in the Palace Hotels of Cannes, Nice or Monte Carlo can offer the zest of the cuisine *chez Chabas*, and for that reason the memory of these eulogistic lines should not be put away in a foggy corner of the mind. It's all very crude and rough and ready; all but the welcome of Chabas and his Arlésienne wife, who wears always the picturesque head-

mediæval walled town, the general outlines being reminiscent of Carcassonne in the Pyrenees, the finest walled relic of its class to be met throughout the length and breadth of France.

Leaving Martigues behind, and heading east towards Marseilles via Carry, Saussay and Estaque, another new world is opened up for the automobilist who has just come down from the sterner north. There are forty-eight kilometers of superb up and down and twisting, turning road from Martigues to Marseilles by this route, mostly by the very fringe of the great, tideless Mediterranean. The background panorama rising off to the eastward of Marseilles is as brilliant and fairylike as anything on the Riviera itself, besides which there is a touch of actuality lent by the smoke of many factory chimneys and the steamships in the harbor, with the prominent accented notes of Notre Dame de la Garde and the Chateau d'If ever in the foreground.

The other route from Martigues to Marseilles still skirts the shores of the Etang de Berre to Marignane, where one should stop long enough to visit the Hotel de Ville, the ancient family chateau of the Mirabeaux. A half a dozen kilometers farther on is Les Pennes, a curiously perched and ravishingly quaint hillside town, with a population of less than a thousand, all living along one main street, and having no occupation in life but to remark on the weather and dance the Farandole and drink their aperitives twice a day on the café terrace of the tree-bordered place, where all through the winter the "*cheminée du Roi et de la Rene*"—the brilliant southern sun—gives all the heat necessary for comfort. Where the money comes from to keep all this population alive is a question—probably from pensions.

Just beyond Les Pennes is the Côte d'Assassins, an ominously-named three kilometers of bad road surface, and as steep a climb

as one will find on any main road in France. The hill climbs up to the crest of the Estaque range and drops down with a much gentler slope on the other to Marseilles without more ado. Its nomenclature is ascribed to two causes; that murderous highwaymen preyed their pestiferous calling here in days past with great regularity—and do to-day less frequently; and that to-day, as ever in the past, a wagon or an automobile gets out of hand and dashes down one side or another of the murderous hill to the death of the occupants, or any who may be in the path. Both explanations are plausible. It's a dangerous hill, either up or down, and the traffic over it is enormous in quantity.

Something About Bustling Marseilles.

The coast down the Mediterranean side to St. Antoine, the first tramway suburb of Marseilles, and so on for another ten kilometers to Marseilles' famous Cannebière, is a continual heart-in-the-throat procedure. One must travel slowly or take the consequences, which are as likely to be as direful for the occupants of the automobile as for outsiders. If you are Riviera bound, branch off the main road just before the Côte d'Assassins and go east via Aix, leaving your machine *en garage* at Aix, and go into Marseilles by electric car

force you must stop and convince the officials that you are not smuggling in a juggled hare or a can of French peas, and thereby defrauding the municipal coffers of some sous.

Marseilles' hotels are of all sorts. The great hotels, like the Louvre et de la Paix or the Grand Hotel Noailles, are big, expensive establishments, excellently appointed and excellently well-kept, but the same sort of thing you will find in Paris with prices about the same. The Hotel de Russie et d'Angleterre is more modest in fit-up and price, and has garage accommodation for three automobiles.

The best thing in the hotel line at Marseilles, for the automobilist or other traveler, is the Hotel du Touring, on the Cours Belzunce, with "*chambres hygiéniques*," and, what's more, hot and cold water in every room and electric light, a combination that is rare in France, or indeed in Europe. It supplies rooms only, and there are no accommodations for automobiles. Its prices are very moderate, and the inconvenience of going outside for your food is one of the pleasures of coming to Marseilles anyway; its restaurants are apparently more numerous, excellent, varied and modest in price than in any other city on the globe.

For garage accommodation one should go to l'Archeveques or the DeDion Agency, Masse

MARTIGUES, THE PROVENCAL VENICE.

AT CHATEAU NEUF.

THE WALLED TOWN OF LES PENNES.

in an hour. You will save the need of a big insurance premium by so doing, also the possible chance of killing yourself.

The last ten kilometers after the crest of the Estaque is simply awful (as indeed are all the roads in and out of Marseilles). There are great, long, tandem-drawn trucks and drays without number, often with five horses in line. There are two lines of tramway all the way, and a bad lot of badly worn pavé as well; besides which there is the Bureau d'Octroi, placed in a most convenient spot, where per-

et Cie., each nearby. It will cost two francs a night for storing your automobile, but land values are dear in Marseilles, and if you want any repairs afterward, such as a new thread or a bolt, probably a franc will cover it. The garage proprietors of Marseilles are not robbers, simply good business men. The days of the overcharging garages are drawing to a close, and one finds more often than not places where the prices are fair and the work mainly satisfactory.

Marseilles, also, is big enough to offer a wide choice.

ROYALTY AT FIRST MADRID AUTO SHOW.

MADRID, May 4.—King Alfonso presided at the inauguration of the first Madrid automobile show to-day in the Palace of Industries and Fine Arts. His Majesty, who was accompanied by the Queen Dowager and other members of the royal family, was received by representatives of the municipality.

French firms take the lion's share of the exhibition space. Only the most important German firms have stands; Britain's representatives are but three in number and the Spanish industry is not able to claim a greater numerical value. Competitions will be held for the most artistically decorated stands and for the most elegant and comfortable bodies. During the two weeks that the show remains open garden parties, bull fights, banquets, balls and galas will be held daily.

GOLD CUP MANAGER LANDS IN EUROPE.

ANTWERP, April 25.—Among the passengers arriving on the Red Star liner "Vaderland" from New York to-day was Georges Dupuy, manager of the American Gold Cup tour. Mr. Dupuy has brought with him a 60-horsepower Stearns, on which he expects to start immediately for Paris. After a few days in the French capital engaging seats for the tourists who will visit the Grand Prix, securing hotel accommodation for the main party, etc., the Stearns will set out on its 6,000 miles run through Europe, covering the entire route to be traveled later by the caravan.

Emperor William and Prince Henry of Prussia, accompanied by several government officials and members of the I. A. C., toured recently over the Taunus course.

TO EXAMINE THE PROFESSIONAL CHAUFFEURS

BOSTON, May 6.—The Massachusetts Highway Commission created consternation in the ranks of the professional chauffeurs last week when it announced that it proposed putting into operation a system of written and road tests for applicants for licenses to operate motor vehicles for hire. The present requirements for obtaining a professional chauffeur's license are very light, the applicant having to swear merely that he has driven a hundred miles or more. But even under these conditions the commission found that many applicants, mostly the product of "Automobile Schools," were perjuring themselves in order to obtain licenses, and that they were really unfit to drive. The Governor also recognized this state of affairs, and in his inaugural address recommended that a board of examiners for chauffeurs be established. The Legislature turned down the Governor's proposition, but it is expected that it will be willing to provide the necessary funds, \$3,000, which the Highway Commission wants to carry out its examination system.

Some weeks ago the commission directed its secretary, A. B. Fletcher, to make an investigation into the professional chauffeur

To Malden — Salem Street — To Medford

STREET DIAGRAM USED FOR DRIVERS' EXAMINATION.

situation, and, as a result of that direction, Mr. Fletcher drafted a system of tests, and has been experimenting upon applicants for licenses. The test is in two parts, one a written examination which counts for 50 per cent., and the other a road test which counts also 50 per cent. It is figured that a candidate who can pass the road test and make at least 15 per cent. on the written test should have a license. The secretary has examined recently forty-one applicants, and eleven of these failed to meet the requirements.

The road test that has been used in the experimental examinations consists of driving up and down hill in clear and crowded streets and turning corners, besides a demonstration of the applicant's familiarity with the machine. The applicant was required to provide the machine with which the examination was made.

If the Legislature provides the appropriation asked for, the Commission will at once put its system of examination into effect. It will probably appoint examiners in most of the principal cities of the State to conduct the examinations, so that applicants will not be obliged to come to Boston. The examination applies only to applicants for professional driver's license, the commission not deeming it necessary to subject applicants for private operators' licenses to such a test. The written examination form used by the commission is as follows:

PART I.—(Written Examination.)—The applicant will answer each of the following questions without assistance from any person and without consulting any book, note or paper of any kind. The answers may be as brief and concise as is consistent with the subject.

1. When, in operating a motor vehicle, another vehicle approaches you, on which side of the center of the traveled way should you pass the approaching vehicle?
2. When you desire to pass a vehicle going in the direction in which you are going, on which side of the center of the traveled way should you pass the other vehicle?
3. When approaching a horse-drawn vehicle or a horse upon which a person is riding, what do you understand is your duty under the laws of Massachusetts?
4. Mark on the diagram the path you should trace in going from Ashland street into Salem street, assuming that you wish to go to Medford. Indicate also the path you would take if you were going to Malden, assuming in each case that the automobile is to start at the point marked "A" on the diagram.
5. As you approach Salem street, describe in detail how you would operate the automobile and just what you would do.
6. Where, in accordance with the automobile law, should the operator's license and the certificate of registration be when a motor vehicle is being operated?
7. Where should the badge of a professional chauffeur be worn when he is operating?
8. Describe how the number plates should be placed on an automobile, and give the rules of the Massachusetts Highway Commission concerning them.
9. During what period should the lighted lamps be on an automobile under operation?
10. What special appliances and safeguards does the law require to be on every automobile?
11. What precautions is an operator required to observe on leaving an automobile in any street, road or public place?
12. What is the penalty for operating an automobile recklessly or while under the influence of intoxicating liquor?
13. When about to leave the garage, shop or place of business of a manufacturer or dealer in a car owned or controlled by a manufacturer or dealer, what is the duty of the operator?
14. What is the provision of the law concerning the attachment of number plates assigned to a motor vehicle to another vehicle to which they do not belong, and concerning the obscuring of the figures on number plates to conceal the identity of a motor vehicle?
15. Define "thickly settled or business part" of a city or town, as used in the automobile law.
16. What speed, under the automobile law, should never be exceeded by a motor vehicle?
17. In excess of what speed, outside of the thickly settled or business part of a city or town, is the rate of speed prima facie evidence of improper operation?
18. In excess of what speed, inside the thickly settled or business part of a city or town, is the rate of speed prima facie evidence of improper operation?
19. In excess of what speed on approaching a crossing of intersecting ways, in traversing a crossing of intersecting ways, or in going around a corner or curve in the highway where the operator's view of the road traffic is obstructed, is prima facie evidence of improper operation?

GEORGIA WILL HAVE AN AUTO LAW.

ATLANTA, GA., May 4.—A bill will probably be introduced at the coming session of the legislature regarding automobiles. The proposed legislation is similar to what has been adopted in a number of other States. The law requiring the registration of owners of automobiles with the Secretary of State is the kind which is now wanted for Georgia. It also provides for registering the name of the owner and his chauffeur. Such a law as the present New York State statute would be considered generally satisfactory by the automobilists of Georgia.

ILLINOIS AUTOMOBILE BILL MAY PASS.

SPRINGFIELD, ILL., May 6.—Indications are that the automobile bill prepared by the Illinois Automobile State Association will become a law. President Sidney S. Gorham has been doing some energetic work. Last week, when the bill was advanced to third reading in the House, Mr. Gorham incurred the wrath of the presiding officer by his persistent lobbying, he urging members to vote against amendments.

AUTO APPRENTICESHIP FOR FRENCH ARMY OFFICERS

PARIS, May 1.—A course in automobile construction has been added to the curriculum of the Ecole Polytechnique, at Paris, the government school in which are trained the cadets for the artillery and engineering services of the French army. M. Darracq has loaned a chassis to be used for demonstration purposes in the school, and as a send off to the new branch of instruction invited the military cadets to visit the huge factory on the banks of the Seine, where are produced such varied types as single-cylinder runabouts and 200-horsepower racing monsters. Over a hundred "Pipos," as the polytechniciens are popularly termed, accepted the invitation and spent a couple of hours wandering through the works with M. Darracq and his most distinguished engineers as guides. Taximeter cabs, small runabouts, and powerful Darracq-Serpellet steamers have called for separate buildings, making the Darracq factory now the largest automobile works in France. Much interest was shown by the military cadets in the Darracq apprentice shop, in which 80 youths undergo a three or four years' training to fit them for positions in the works.

In our illustration the future army officers are shown around a six-cylinder chassis, the features of which have been explained to them by one of the engineers. M. Darracq is standing on the extreme left, Paul Ribeyrolles, chief designer, is in the center, and M. Vacherot, business director, is on the extreme right.

Although the French military authorities own but a small number of automobiles, a large quantity of material is put at their disposition through the operation of the conscription laws. In case of necessity the army can requisition thousands of automobiles now in private service and can call to the colors the pick of the mechanical world at a few hours' notice. Thus the method of making use of the automobile as an auxiliary of the army is entirely different to that of countries where military service is voluntary.

After two years active service in the army, every Frenchman must serve two periods of twenty-eight days each with the colors, followed by a couple of periods of thirteen days each, and is liable to be called on for active service in the army until the age of 45. Not only is he required personally, but his automobile, or any other vehicle he may possess, must be put at the disposition of the military authorities at certain intervals. When called upon to pass his twenty-eight days in the field, the reservist, if he is the happy owner of an automobile, takes his machine with him, is attached to the headquarters staff, and passes a much easier four weeks than if he had a knapsack slung on his back and a rifle over his shoulder. Occasionally a rich reservist will provide not only his machine, but a chauffeur in addition. Most of the cars used in the *grands manoeuvres* are supplied in this manner. Among the officers there are a certain number thoroughly versed in automobiling and capable of organizing an automobile corps to the best advantage from the diversified material placed at their disposition at all the

great mobilizations. The new course at the Ecole Polytechnique will tend to increase the number of such men, and even though they may not all become experts of the highest order, they will have a knowledge of the automobile in general and be better fitted to make use of this auxiliary in time of war.

Among the officers having paid special attention to the automobile for army purposes none is better known than Captain Genty, who figures in all the important French automobile races under the *nom de guerre* of De la Touloubre. Familiarly he is known as *tant que ça peut*, which may best be translated by "never give in." In the Ardennes and last Gordon Bennett on a Darracq, in the Grand Prix on a Bayard-Clément, De la Touloubre has shown himself a daring driver and skilled mechanic.

Only a few days ago an example was afforded of the part private automobiles would play in the army in case of mobilization, at the Vincennes garrison. Orders were given for all machines available for service in that district to be assembled at the old fort. Seventy automobiles of every possible type gathered

for the peaceful mobilization, among the drivers being such well-known automobilists as M. Dumont, the son-in-law of M. Clément, with a Bayard-Clément, Pawlowsky, the motor journalist, and Edmond, the Renault racing driver. Instead of the summary inspection to prove that the machines were capable of performing the service that the Government may demand of them, Captain Genty made a speech to his chauffeur reservists, telling them that it was his intention to put them to a practical test. "En avant," and the battalion of Pan-

EXPLAINING FEATURES OF DARRACQ "SIX" TO FRENCH MILITARY CADETS.

hard, Renaults, Brasiers and others was led into the hilly district in the neighborhood of the Marne. After four hours' traveling, including a grade of 18 per cent., which they were not all able to negotiate, the troop was led by its captain back to the garrison and dismissed from service.

There are probably about 250 machines belonging entirely to the army and in constant service. All of these are used for transport work and are all of special design to meet the requirements of the particular branch of the army in which they are used. The major portion are naturally designed for carrying ammunition and stores; a smaller number have tank bodies for the rapid transport of water, and a few are employed in the red-cross service. Delahaye, Peugeot, Dietrich, Gillet-Forest and Panhard are the firms having supplied most of the army vehicles. Drivers and mechanics for these machines are at hand in the young workmen who have left the automobile factory for a couple of years to wear the ill-fitting uniform that the patrie provides free. At the present moment Albert Clément is undergoing a three years' military training, and there are always hundreds of others, less conspicuous in the eyes of the public, but just as capable of handling a military automobile wagon as the dashing driver of the Bayard-Clément factory. Conscription provides the fast machines needed for officers' use.

HEARD IN AND ABOUT THE CLUB ROOMS

Quaker City to Attend Wilkes-Barre's Big Climb.

PHILADELPHIA, May 6.—Knocked about from pillar to post in its efforts to secure a suitable course for its Decoration Day hill climb, the Quaker City Motor Club, at its regular monthly meeting at the Majestic, decided to abandon the event entirely. While Monk's Hill, the course finally decided upon by the Contest Committee, had not been forbidden them, the glowing accounts of the fun in store for the Quakers if they would drop their climb and go up to Wilkes-Barre and contest for the prizes there, turned the balance in favor of the latter.

The new scheme had an ardent advocate in C. W. Matheson, president of the Matheson Company, who came all the way down from Wilkes-Barre and talked so glowingly about "keys of the city" and "nothing too good for you" that the vote in favor of the change was practically unanimous.

The Quaker City members will make a three-day outing of it, going up on the 29th and returning on the 31st. To insure some plunder for the Philadelphians, the Wilkes-Barre Automobile Club climb committee will add a couple of special events open only to them. Quite a few Quakers, however, will also enter the open events.

Baltimore's Club to Have Touring Series.

BALTIMORE, May 6.—The first of the series of the H. M. Rowe touring contests, which are to be held under the auspices of the Automobile Club of Maryland, will take place June 7. The remaining two of the series will be held in September and October. The tour, which will be held in June, will be from this city to Hagerstown and return, a distance of 150 miles, while the next run will be over 200 miles, and the last run will be 400 miles. The contests will differ from the Glidden tours in that no professionalism will be allowed, and the owners will be compelled to drive their own cars. A handsome trophy will be awarded to the winner by Dr. H. M. Rowe, one of the automobile enthusiasts of this city.

Arrangements are being made by the local organization to entertain over 800 children on June 12, which has been set aside by the American Automobile Association as Orphans' Day. The children will be given a ride through the city and the Green Spring Valley, after which they will be entertained at luncheon. The automobiles necessary will be furnished by the Automobile Club of Maryland and the garages.

Committee Chairmen for Wilkes-Barre Auto Club.

WILKES-BARRE, PA., May 6.—The Wilkes-Barre Automobile Club officers are busily engaged on the plans for the May 30 hill climb, the scene of which will be "Giant's Despair," up which a successful contest was run last year. President P. A. Meixell has named C. W. Matheson, W. E. Steelman, Laning Harvey and George Lee as a committee to decide upon the events and also complete arrangements with the Quaker City Motor Club, of Philadelphia, for the endurance run from that city to Wilkes-Barre. The regular committee chairmen named by President Meixell are as follows: Good roads, R. B. Vaughn; membership, W. F. Newberry; entertainment, E. W. Davis; club runs, P. A. Wright.

Yale's Autoists to Have Another Meet.

NEW HAVEN, CONN., May 6.—The recently-organized Yale Auto Club will hold its second auto meet at the Branford Driving Park on the afternoon of May 11. The list of events includes motorcycle races, open and college races for touring cars and racers. Gold, silver and bronze medals will be awarded to the winners in the different events. Entries should be sent to W. P. Morden, 124 Wall street, New Haven.

Buffalo Club Answers the Bison City's Mayor.

BUFFALO, N. Y., April 6.—The Automobile Club of Buffalo has answered the Mayor's criticism of the club's action in engaging a former Supreme Court justice to test the legality of the new vehicle ordinance requiring automobilists to pay an annual license of \$5 each. In its statement the club says:

"In view of the criticism of the Mayor, the Automobile Club of Buffalo desires to make its position clear with reference to the recent ordinance imposing a tax upon automobiles for the use of highways in the city. This ordinance was passed in total disregard of a general law of the State, which forbids any municipality enacting ordinances the effect of which is to exclude automobiles from the free use of highways. We purpose testing the validity of this ordinance in the courts. We have always assumed that it is one of the inalienable rights of a citizen, either individually or in conjunction with others affected in like manner, to ask for a judicial decision as to the validity of any law which may affect him either in person or property, and we cannot see how the exercise of that right is a fair subject for criticism.

"If this city can impose such a tax, then other municipalities may assume the right to tax automobiles for the privilege of passing over their highways, whether the owners be resident or non-resident, and the cumulative taxes thus imposed would become practically prohibitive of the enjoyment of our property. The ordinance imposes a tax of \$5 upon automobiles, while other vehicles are taxed \$1 or \$2. Such discrimination cannot be justified upon a fair comparison of the wearing effect on the pavements between automobiles and other vehicles."

A total of sixty-four applications for active membership were favorably received at last Saturday's meeting of the Automobile Club, bringing the total membership up to 711. With the exception of the Automobile Club of America, the Buffalo club is now the largest individual automobile club in the world. Of course, not all members live in Buffalo. However, local autoists appreciate the value of the club membership. During the past winter thirteen objectionable bills were brought up at Albany, but were defeated principally through the efforts of the Buffalo club.

Exciting Election of Newark's Flourishing Club.

NEWARK, N. J., May 6.—The annual election of the New Jersey Automobile and Motor Club to-night was the most exciting affair in the history of the organization. If the Chancery Court decides that proxies are allowable, the following ticket was successful: President, Angus Sinclair; vice-president, L. T. Wiss; treasurer, J. C. Coleman; secretary, H. A. Bonnell; trustees, J. H. Wood, W. F. Kimber, W. C. Crosby.

With the 135 proxies cast and counted, Mr. Sinclair received 198 votes; Mr. Wiss, 203; Mr. Coleman, 207; Mr. Bonnell, 213; Mr. Wood, 201; Mr. Kimber, 197; Mr. Crosby, 198.

The independent nominees received the following votes: President, William C. Shanley, 97; vice-president, Frederick C. Pratt, 92; treasurer, William I. Fisk, 88; secretary, Leslie T. Ward, 82. Trustees: Charles W. Baker, 100; Edison Z. Seitz, 93; Dr. Frank B. Meeker, 96.

It is expected that there will be a quick decision from the Chancery Court on the constitutionality of voting proxies, the club being incorporated under the State law.

Bridgeport Autoists Announce Their Hill Climb Program.

BRIDGEPORT, CONN., May 6.—Considerable interest is being displayed in the hill-climbing contest to be held at Sport Hill, Easton, on May 30, under the auspices of the Automobile Club of Bridgeport. The hill, which is one of the best known in Eastern Connecticut, and is five miles from Bridgeport, is about

one and a quarter miles in length, and has some steep grades.

The events have been arranged on the basis of selling price. Cars selling up to \$1,000 inclusive in class 1; up to \$2,000 inclusive in class 2; up to \$3,000 inclusive in class 3; over \$3,000 in class 4. Free for all, open to stripped touring cars and stock runabouts up to \$5,000, will compete in class 5. Entry fee is \$5. Elegant and valuable silver prizes will be awarded winners in all classes. A. L. Riker will be marshal, and the timing of the cars will be in charge of A. K. L. Watson and Archibald McNeil. Chairman Ralph M. Sperry, of the hill-climb committee, announces that all events are open, and autoists from all sections are invited to attend.

St. Paul Automobile Club to Have a House.

ST. PAUL, MINN., May 6.—A clubhouse and garage for the Automobile Club of St. Paul is assured and work upon a building, 75 by 138 feet and two stories high, will be begun at once. The building will be located on Fourth street, between Minnesota and Cedar streets, in the heart of the city. The definite announcement of the success of the clubhouse plans was made at a banquet given by the club at the Commercial Club last week. The building will be erected by Oscar L. Taylor for the club, and will have a garage on first floor and commodious rooms on the second. The membership of the club is now 125, and it is expected that it will reach 200 during the summer.

The banquet of the club was an enthusiastic affair, with representatives of the Minneapolis Automobile Club and other State association clubs in attendance. L. A. Wood acted as toastmaster and President Frank M. Joyce, of the Minneapolis club; Ambrose Tighe, president of the St. Paul Club; Judge Finchout, George H. Daggett, of Minneapolis, and others made addresses.

Annual Gates' Mill Climb of the Cleveland Club.

CLEVELAND, O., May 6.—Without doubt the hill climb of the Cleveland Automobile Club at Gates' Mill, east of Cleveland, this year will prove of greater interest than ever before. So many manufacturers and representatives of foreign cars are making inquiries regarding the event that it is likely to take on an aspect of international importance. In part the open challenge of F. B. Stearns against all comers is responsible for the attention that has been attracted toward this event. As yet the entry blanks have not been issued, but many inquiries have already been made for them.

The hill at Gates' Mill is being prepared for the test in the best manner possible. The only really dangerous curve has been banked and the course graveled and steam rolled. It will be in admirable shape in every way.

First Run of the City and Country Motor Club.

NEW YORK, May 6.—The first run of the City and Country Motor Club to the Lake Mahopac clubhouse was held yesterday, some twenty cars participating in the pleasure jaunt. On the return J. Stuart Blackton was the victim of a "holdup" in the village of Briarcliff, the rural Justice of the Peace giving the prisoner the choice of one of three penalties, the court announcing its decision in this manner: "Either loan me \$200, which you may call bail; stay in jail here until next week; or pay a fine." The victim decided to pay the \$30 fine, realizing that he was in the hands of the enemy.

The Cohoes Automobile Club, of Cohoes, N. Y.

COHOES, N. Y., May 6.—The Cohoes Automobile Club has been formed with a membership of 35 and the following officers: President, Dr. J. H. Mitchell; vice-president, J. Henry Williams; treasurer, F. J. Gardiner; secretary, E. R. Clifton. The club is a member of the New York State Automobile Association of the A. A. A. Meetings have been held at the garage of Kennedy & Son, but subsequently other quarters will be obtained.

**THE AUTOMOBILE CALENDAR.
AMERICAN.**

Shows and Meetings.

- May 28-31.....—Indianapolis, Ind., Annual Meeting American Society of Mechanical Engineers.
- Oct. 31-Nov. 7...—New York City, Madison Square Garden, Eighth Annual Automobile Show, Association of Licensed Automobile Manufacturers.
- Nov. 30-Dec. 7...—Chicago, Coliseum and First Regt. Armory, Eighth Annual National Automobile Show and First Annual Commercial Vehicle Show, National Association of Automobile Manufacturers.

Races, Hill-Climbs, etc.

- May 30.....—Wilkes-Barre, Pa., Second Annual Climb, "Giant's Deepair," Wilkes-Barre Automobile Club.
- May 29-31.....—Philadelphia to Wilkes-Barre and Return. Endurance Run of the Quaker City Motor Club.
- May 30.....—Chicago, Memorial Day Race Meet of the Chicago Motor Club.
- May 30.....—New York City, Race Meet, Empire City Track, for Oldsmobile cars.
- May 30.....—Bridgeport, Conn., Hill Climb, Bridgeport Automobile Club.
- May 30-June 1...—Newark, N. J., Three-day Endurance Run of the New Jersey Automobile and Motor Club.
- June 12.....—National Orphans' Day, instituted by the American Automobile Association.
- June 19-22.....—New York City, Sealed Bonnet Contest, under the auspices of the Automobile Club of America.
- June 20.....—Albany, N. Y., Annual Tour of the Albany Automobile Club; Route, via New York and Asbury Park, to Atlantic City.
- June 27-28.....—Chicago, Elgin-Aurora Reliability Run, Chicago Motor Club and Chicago Automobile Trade Association.
- July 10.....—Cleveland, O., Start of Fourth Annual Tour of the American Automobile Association, for the Glidden Trophy. Finishes in New York City on or about July 23.
- Aug. 1.....—Algonquin, Ill., Hill Climb, Chicago Motor Club and Chicago Automobile Trade Association.
- Sept. 5.....—Chicago, Cedar Lake Economy Run, Chicago Motor Club and Chicago Automobile Trade Association.
- Sept. 14.....—Albany, N. Y., 95-mile Road Race, under the auspices of the Albany Automobile Club.

FOREIGN.

Races, Hill-Climbs, etc.

- May 15-31.....—Belgium, Industrial Vehicle Trials, Automobile Club du Nord.
- May 18-21.....—Milan, Italy, Touring Club Trials.
- May 22-25.....—Irish Automobile Club Reliability Trials.
- May 24-27.....—Voiturette Contest, Automobile Club of Austria.
- May 28.....—Isle of Man, Tourist Trophy Race, Automobile Club of Great Britain and Ireland.
- May 30.....—Isle of Man, Heavy Touring Car Race, Automobile Club of Great Britain and Ireland.
- June 3-12.....—Paris, Electric Vehicle Competition, Automobile Club of France.
- June 3-12.....—Herkomer Cup, Automobile Club of Bavaria.
- June 10.....—Pekin-Paris Automobile Tour, Start from Pekin, Inaugurated by "Le Matin."
- June 14.....—German Emperor's Cup, Taurus Circuit, Imperial Automobile Club.
- June 20-22.....—American Gold Cup, Start from New York of European Tour for American Cars, Georges Dupuy, secretary, 1402 Broadway, New York City.
- June 14-29.....—Scottish Reliability Trial, Scottish Automobile Club.
- July 2.....—Grand Prix, Automobile Club of France.
- July 14, 1908.....—Paris to London, Aerial Race.
- July 15-18.....—Ostend Week, Record Trials, Automobile Club of Belgium.
- July 21.....—Ardenne Circuit (Belgium).
- July 31.....—Liederkerke Cup for Touring Cars, Ardenne Circuit, Belgium.
- July 31-Aug. 8...—Belgium Regularity Contest for Touring Cars, A. C. of Belgium.
- Aug. 1-7.....—Criterion of France, 1,750 Miles Touring Competition and 250-mile Race for the Press Cup, A. C. of France.
- Aug. 11-29.....—France, Coupe de Auvergne.
- Sept. 1.....—Italy, Brescia Circuit, Florio Cup, A. C. of Italy.

Is There a Place for the Second-Hand Car? In the early days of the great wave of popularity of the bicycle that swept over the land, models changed so quickly and so radically that the dealer looked askance at the purchaser who requested that his former mount be taken in trade. History repeated itself in the case of the automobile, and for the first three or four years the dealer confined himself to new cars, and most of the dealers would have preferred to see things remain thus. In fact, many of them set their faces resolutely against inaugurating the practice, but all to no purpose. Not that all have been compelled to adopt it, but circumstances proved too strong for many, while others have done so as a matter of policy. The time was not long in coming when the purchaser who invested in a new car every season held his order until he could dispose of his used car. This buyer represented a relatively large class, and it paid so well to cater to him that the dealers found it profitable to bid for him, and thus his car was taken off his hands, and the practice imperceptibly took hold. Except for the fact that it necessitated larger quarters for the storage of such cars and the maintenance of a larger repair force, there appears to be no reason why there should have been any hesitation about adopting the practice, except on the part of the manufacturer, who considered it wholly out of his line. But how about the common garden variety of second-hand car and the second-hand dealer? A thousand and one reasons bring as many used cars into his hands; they are in all conditions and of all sorts, but in many cases much of the depreciation is fictitious. It is not actual mechanical depreciation, as measured by

the normal life of such a piece of machinery with reasonable care, and it is probably safe to say that a great many, if not a majority of the cars that find their way into the mart of the cast-offs, have a useful life of several years before them—again with reasonable care, of course, for abuse shortens mechanical as well as human life. Is there a place for such cars? The thousands of them that change hands ever year would appear to give an emphatic affirmative to the question.

There Will Soon Be No More Worlds to Conquer. When the automobile first distinguished itself by demonstrating its ability to cross the American Continent in record time, it was justly considered that here, indeed, was a conquest that would be hard to surpass. Since then the Continent has been crossed and recrossed, and, though the first attempts were considered something of a marvel in the shape of rapid travel under such trying conditions, the time has been cut in half. It is not too much to say that granted half the advantages possessed by the railway train in the shape of a solid roadbed with easy grades and curves, the automobile could make a cross-continental record, lowering the time of the best through mail trains.

Trips such as those referred to have become so tame by frequent repetition that enthusiastic believers in the capability of the auto have had to go further afield for something worthy of their mettle. Hence the Pekin-Paris propaganda, which is not merely a test of endurance, but a race. The daring nature of the project is such that no reward would appear sufficient to induce competitors to enter in such a trial, yet with no stake other than the glory of achievement, no less than fourteen cars have been shipped to the Far East with some of their drivers and the remainder have already left by rail. There is no reason to doubt that at least some of the competitors will succeed in traversing the 8,400 miles—much of which is an unknown wilderness—in what may be considered record time. Among the drivers there are some who have demonstrated their ability to take an automobile anywhere that four wheels can be made to run, so that it would seem as if the automobile would soon have no more worlds to conquer.

The Automobile as an Aid to Fire Fighting. With the present high factor of reliability that the past few years of improvement have brought it, the automobile stands second to nothing in its unification of all those qualities that go to make the fire-fighting machine par excellence. Its speed, ease of control, weight-carrying capacity and wide radius of action place it at once so far beyond any other known method of transporting fire apparatus to the scene of action as to render any comparison utterly out of the question. Numerous instances of its value in this rôle could be brought to bear. But a short time ago the services of three automobiles saved a Western town from total destruction; it was without adequate fire protection and half the town had already gone down before the fire, when the automobile saved the day. To do so, it had to cover twenty miles of rough road intervening between there and the nearest help. Other instances of an equally convincing nature are not wanting, and in all of them the rôle is played by the stock touring car. How much more effective would the specially designed machine, not alone providing its own motive power, but also carrying its own fire-fighting apparatus, prove in such emergencies? The question is readily answered at home as well as abroad. Paris and other Continental cities have come to regard the automobile fire engine as a matter of course; it represents an innovation that was inaugurated two or three years ago in quite a few instances, and not alone its permanency in this rôle, but its eventual usurpation of it to the exclusion of the horse is looked forward to at no distant day. Progress has not been so rapid here, but the all-round capacity of the automobile for this work makes it only a matter of time when it will be the mainstay in serious fire-fighting the world over.

LAYING OUT THE A. A. A. TOUR ROUTE.

On Tuesday morning last Dai H. Lewis, secretary of the Touring Board of the American Automobile Association, left Buffalo in a Pierce-Arrow six-cylinder to map out the course for this year's A. A. A. tour. He is accompanied by a photographer, and Chairman F. B. Hower, of the Touring Board, under whose direct supervision the work is being carried out, will be with him a part of the time. Distances are to be carefully measured, and all landmarks and turns in the road are to be noted. In the tour itself, the "Big Six" Pierce car will probably act in the same rôle as last year—that of picking up the checkers, it having been secured as the chairman's official chariot.

After due consideration, it has been decided to make the Hower trophy, which is now on exhibition at the Harrolds Motor Car Company's salesrooms at 1789 Broadway, an individual, instead of a club prize, to be won permanently by one entrant. The trophy is a four-foot bronze figure entitled the "Signal Man," who holds a torch above his head in one hand, a spear at rest in the other, while a fire burns at his feet. Its relation to automobiling is problematical, though there is no doubt as to its status as a work of art. A new set of rules, under which it is to be competed for, are now being compiled.

The most important announcement in connection with the tour made up to the present is to the effect that the tourists will go "a-Cooking" it this year, instead of having to rely upon the efforts of amateur advance men for proper hotel accommodations. It will be easier to do this, as nearly all the stops will be made in large cities. No stone is being left unturned by the committee, however, to insure satisfaction for all concerned. Work was undertaken several weeks ago, and the hotels will be obliged to sign contracts not to raise their rates in any way. A professional advance man engaged from Thomas Cook & Son's will precede the tourists and make all arrangements. He will carry a complete list of the occupants of each car and of the parties traveling together, and will inspect rooms and make all allotments, leaving his record for the checker-in at each point when he goes ahead. The checker-in will hand each arrival a card giving full information as to where cars are to be garaged, the name of the hotel, and the numbers of the rooms. It is thought that the services of an experienced professional should result in obtaining as nearly as possible the accommodation that each tourist desires. The advance man will keep in communication with the managers of the tour by telephone.

FIRST ENTRY FOR VANDERBILT CUP RACE.

Although regulations for the next Vanderbilt Cup contest have not yet been issued, a car has already been entered for the great American automobile race. The early arrival is the 85-horsepower B. L. M. machine which was entered for the elimination trial last year, but was not completed in time to participate.

Announcement is made by the Royal Motor Car Company of their intention to construct two high-powered flyers for the Vanderbilt Cup race, and of the return of Robert Jardine to the racing game. The two machines will be strictly American, being built without the help of foreign designers, designs or materials. E. D. Shurmer, president of the company, expresses his confidence in their ability to make a creditable showing.

The three Thomas racers which have been under construction during the winter for the next Vanderbilt Cup race will be ready to turn over to their drivers for the preliminary tests by June 1 at the latest. They might have been put on the road by May 1, but positive orders were given some time ago that there should be no hurry in the assembling. However, with the picked men in charge and the experience they have had on racing cars, the work has progressed much faster than was expected. With the motors especial care has been taken; they are now on brake test and will be kept there for two weeks at the least, and will be given road practice after June 1.

ASSOCIATED AUTOMOBILE CLUBS OF N. J.

TRENTON, N. J., May 6.—W. F. Sadler, Jr., is the new president of the Associated Automobile Clubs of New Jersey, and it is anticipated that the State organization of the A. A. A. will greatly increase in membership during his administration. With K. G. Roebbling, Mr. Sadler organized the Mercer County Automobile Club, and these two were prominent in the fight against hostile

PRES. W. F. SADLER, JR.

automobile legislation in 1905, their efforts being quite successful. In 1906 the Frelinghuysen bill occupied the center of the stage, and though it passed with features objected to by automobilists, there were several classes stricken out which have made the measure still more onerous. Upon the Trentonians devolved the burden of the work, but, of course, the backing of the State body was a factor in the effort to stem the tide of drastic lawmaking.

J. E. Gill, another member of the Mercer County Automobile Club, is secretary and treasurer of the State organization, the other directors of which are the following: Judge James B. Dill, Automobile Club of New Jersey; F. R. Pratt, J. F. Baker, New Jersey Automobile and Motor Club; W. G. Norwood, North Jersey Automobile Club; Walter E. Edge, Atlantic City Automobile Club; K. G. Roebbling, Mercer County Automobile Club; W. N. G. Clark, Monmouth Automobile Club; Col. F. M. Barksdale, Automobile Club of Cape May; Dr. F. C. Ard, Union County Automobile Club.

WISCONSIN'S A. A. A. STATE ASSOCIATION.

MILWAUKEE, Wis., May 6.—At the May 16 meeting the Wisconsin State Automobile Association will elect its officers. These are the probable selections for directors: Neal Brown, Wausau; C. O. Josslyn, Oshkosh; F. H. Blodgett, Janesville; Dr. L. F. Bennett, Beloit; W. G. Menzen, Fond du Lac; Judge W. S. Stroud, Portage; E. Roy McCanna, Burlington; Rich T. Robinson, Racine; C. A. Harper, Madison; A. R. Hoard, Fort Atkinson; Charles T. Jeffery, Kenosha; F. P. Hixon, La Crosse.

Three directors from the Milwaukee club will be named, and Secretary James T. Drought will undoubtedly be one of the directors selected.

The officers will be selected from among the directors, and it is probable that either Neal Brown, of Wausau, or C. O. Josslyn, of Oshkosh, will be selected president, while it is generally conceded that James T. Drought, of Milwaukee, will be offered the position of secretary.

GEORGIA CERTAIN TO FORM A. A. A. BODY.

ATLANTA, GA., May 5.—A large and enthusiastic meeting of the Atlanta automobile owners and users was held at the Capital City garage to discuss the formation of a State automobile association. At the meeting no plans were made toward organization, as the backers of the movement first wished to see how the owners regarded the matter. It was clearly shown at the meeting that the majority of the local owners are very desirous to have a State body, and will heartily back any movement toward organizing one.

The American Automobile Association is working hard for good roads, which is one of the most important matters that faces an automobile owner in the South.

Another meeting of the local automobile owners will be held at an early date, and it is thought plans will be perfected for an organization of a State association. As the movement is backed by the leading automobile owners, it is sure to go through.

MODEL E, AEROCAR TOURING RUNABOUT.

BENJAMIN'S FIRST NEW MODEL AEROCAR.

DETROIT, MICH., May 6.—C. A. Benjamin has just brought out his first new type of car since assuming his position as vice-president and general manager of the Aerocar Company. Although this concern build both water and air-cooled cars, Mr. Benjamin has stuck to his past reputation and is making this initial car an air cooler. The car was designed by Leo Melanowski, chief engineer of the Aerocar Company. It is of the touring runabout type and has a clean cut racy appearance. For practical service this new model will meet a demand that has been given but little consideration. It is the requirement of the suburbanite in having a car with which he can carry a trunk, or two trunks, if necessary, from the station or city to his country home. The nobby rumble seat is convenient for a third person. Underneath it is a space large enough to put a suit case, robes or wraps, where they are under lock and key. Remove two bolts and the whole back can be easily set off and left at home.

Briefly the chassis has a wheelbase of 105 inches with 34x3 1-2-inch wheels. The motor is 20-horsepower, four-cylinder, air-cooled. The new Aerocar multiple disc clutch is used. The transmission is of the sliding gear type with three speeds forward and reverse. A shaft drive with bevel gear floating differential in the rear axle is used.

The batteries are carried in a box strapped on the running board on the right side of the car. The connection between them and the coil is short, so that it is easy to locate any possible ignition troubles. There is no crawling under the car to find a defective wire. On the left running board a similar box is strapped and is used as a tool box.

The machine is finished in a French gray with black moulding, while the gear is Italian red. The upholstery is of red leather, and instead of the old tufted style has that snappy appearance that is more in keeping with the rest of the car. It makes the seats exceedingly comfortable. The price is \$2,000.

ENLARGING MITCHELL FACTORY AT RACINE.

RACINE, WIS., May 6.—The new buildings of the Mitchell Motor Car Company's factory will give between 55,000 and 60,000 square feet of additional floor space, all on the ground floor, and more than half of which will be devoted to machine shop facilities. The construction is like that of the other buildings, cement with saw-tooth roof and fireproof. The increased facilities will enable the Mitchell plant to make 2,200 cars in 1908, exclusive of commercial vehicles, the business for which is increasing rapidly.

Plans for a still larger plant have been made and accepted for 1908, and this work will be begun in the Spring of 1908, just as soon as the frost is out of the ground. J. W. Bate, the company's engineer, is responsible for some special machine tools that will assist materially in the economical manufacture of Mitchell cars. Eight cars per day is the present capacity and this is expected to be increased to ten in the near future.

AUTO A FEATURE OF A. S. M. E. MEETING.

At its spring meeting, to be held at Indianapolis, Ind., from May 28 to 31 next, the American Society of Mechanical Engineers will devote one of its entire sessions to the reading of papers on different features of automobile construction. The Claypool Hotel will be the society's headquarters during the meeting, which will be opened by an address of welcome and a response by Prof. Frederick Remsen Hutton, of Columbia University, in the auditorium of the hotel on Tuesday evening, May 28. This will be followed by a social reunion. Wednesday morning will be devoted to a business session to hear the reports of standing and special committees and to vote on amendments. The afternoon session of that day will be taken up with the report of the Committee on Standard Proportions for Machine Screws, and the preliminary report of the Committee on Refrigerating Machines. Papers will be read by Reid T. Stewart on the "Collapsing Pressures of Lap-Welded Steel Tubes;" A. F. Nagle, on "The Balancing of Pumping Engines," and "A Comparison of Long and Short Rotary Kilns" by E. C. Soper.

Wednesday evening is to be an "automobile symposium." The papers to be read are entitled "Bearings and Moving Mechanism," by Henry Hess, of the Hess-Bright Manufacturing Company; "Air-Cooling of Automobile Engines," by John Wilkinson, of the H. H. Franklin Manufacturing Company; "Materials for Automobiles," by Elwood Haynes, the Haynes Automobile Company; "Special Auto Steel," by Thomas J. Fay, and "Railway Motor Cars," by B. D. Gray. On Thursday morning, superheated steam practice will be considered from various points of view in four papers by A. R. Dodge, A. M. Greene, E. H. Foster and R. P. Bolton. Thursday afternoon and evening will be devoted to an excursion and reception. Friday morning the members will visit Purdue University, at Lafayette, Ind., *en masse*, and a professional session will be held in one of the university buildings, the subject being a continuation of the consideration of superheated steam practice, four additional papers being read by W. F. M. Goss, G. H. Barrus, H. H. Vaughn, and S. L. Kneass, supplemented by papers entitled "A Hirn's Analysis of Locomotive Test," by S. A. Reeve, and "The Heating of Storehouses," by H. O. Lacount. Other papers are expected to be read at the various sessions, but have not yet been listed. The University of Illinois, situated at Urbana, Ill., has also extended an invitation to the members to make a visit there, where they will be received by Dr. L. P. Breckinridge, professor of mechanical engineering and director of the Government research station.

SIMPLEX MOTOR CAR CO. JOINS A. M. C. M. A.

The American Motor Car Manufacturers' Association now has a total membership of 42 automobile manufacturers. The latest concern to join is the Simplex Motor Car Company, of Mishawaka, Ind., makers of the Simplex cars.

In the recent vote of the A. M. C. M. A. only one of the 42 members objected to a strenuous tour, this one preferring a pleasure trip without rigid rules. All but two voted for an average run of 125 to 150 miles per day, and one suggestion was made for a pacemaker. There was not a single objection to the rule preventing the replacing of any parts on a car that would not ordinarily be carried on a regular tour. On this point there was no difference of opinion.

DOLSON AUTOMOBILE CO. ENLARGES ITS PLANT.

CHARLOTTE, MICH., May 6.—Removal of the machinery of the plant of the St. Ann (Ill.) Kerosene Motor Company, recently purchased by the Dolson Automobile Company, of this city, is being rapidly consummated, and the new factory building of the Dolson company is making rapid progress toward completion. The new addition to the factory is a very expansive one-story structure, well lighted, and when finished will accommodate 600 workmen.

ENDURANCE RUN of the MOTOR CLUB of HARRISBURG

BUSTLING YORK, THE NIGHT STOP OF THE RUN, IS PICTURESQUELY SITUATED IN THE VALLEY.

YORK, PA., May 6.—At the end of the first day's run of the two-day endurance contest, held under the auspices of the Motor Club of Harrisburg, 15 cars of the 31 which made the trip over the 93 miles of good, bad and indifferent roads, have arrived here with perfect scores to their credit. Up to this point the run has been as successful as any of its character ever undertaken in the East, and is unmarred by serious accident.

Among the contestants are autoists famous the country over: G. Hilton Gantert, of Philadelphia, with his Oldsmobile "Mudlark"; Walter C. White, of Cleveland, with one of the cars which bears his name, and H. A. Grant, of Maxwell-Glidden tour fame. The latter had the only spill so far reported, but luckily escaped with the other occupants of the car.

The cars of the contestants, preceded by those of the officials, left Harrisburg this morning, the first at 8 o'clock and the others at one minute intervals. From Harrisburg the route led through Hummelstown and thence to Lebanon, the first checking station. From Lebanon the route led through Bismarck, Manheim, Petersburg, and Lancaster. The second checking station was fixed at the last named place. From Lancaster the run continued through Mt. Joy, Marietta, and Columbia, where the third checking station was located at the Northern Central railroad bridge over the Susquehanna river. From Columbia the run led

into Wrightsville and thence into York, to the night control at the garage of the York Motor Car Company.

First to arrive was the White pilot car, in charge of R. H. Johnston, of the New York Motor Club, from which confetti was scattered. As it sped through Center square an unknown man was run over, but as the crowd rushed to his assistance he arose unhurt. First of the contestants to come in was the first car to start and the hero of the race, a little "one lung" Cadillac runabout. On the run between Lebanon and Lancaster this car, driven by C. C. Crispen, of Harrisburg, skidded off a loose stone, dove through a fence, carrying part of it away, and then regained the road again without stop or injury. The plucky little car finished with a clean score.

REFEREE E. C. JOHNSON.

Another which met with an accident yet finished with a clean record was a Pullman car driven by James A. Kline, of York. A tree overhanging the road shaved off its top. The "Jonah" of the race was the committee car, a Winton, and No. 13, which had five punctures and came in here on a flat tire, but ahead of the checking schedule.

There were other hard luck stories. A Mitchell car, driven by W. O. Hickok, of Harrisburg, had a clean record until within a mile of York, where a tire burst, and 42 minutes, and consequently 42 points, were lost. J. E. Sellers, who started with a

THE START WAS MADE FROM HARRISBURG IN MUGGY WEATHER.

CHECKING STATION IN THE PUBLIC SQUARE AT LEBANON.

C. A. GILBERT, THE DRAGON CONTESTANT.

WALTER WHITE, A FREQUENT PARTICIPANT IN RUNS.

Pullman, claimed that his gasoline had been watered and was forced to fall out. Robert Shirk, of Philadelphia, with a Stoddard-Dayton, lost 84 points by getting to Lancaster 42 minutes ahead of time.

The contestants found good roads over most of the course, though a stretch of about a dozen miles between Lebanon and Lancaster was in poor condition. Many of the belated ones made up time on the run over the fine macadam pike between Wrightsville and York. They sped to York, and raced through long lines of cheering spectators to the night control station.

The last of the machines was scarcely in before a heavy shower fell and predictions were made that on the remaining 116 miles of the course the mudlarks would have their inning.

More than 100 of the autos rested here to-night and were entertained by the York lodge of Elks.

At Marietta to-day a grand reception was tendered the contestants. The fire department turned out and bells were rung as the cars passed through. Hanover removed all speed limits.

Four Perfect Scores: Pullman, Thomas, Pierce, White.

HARRISBURG, PA., May 7.—Four touring cars finished the two-day endurance run with perfect scores. They were:

- No. 8. Pullman, 40-h.p.; E. G. Irvin.
- No. 18. Thomas, 60-h.p.; S. K. Hamburger.
- No. 32. Pierce-Arrow, 35-h.p.; H. F. Rawl.
- No. 36. White steamer, 30-h.p.; Walter C. White.

In the runabout class there was only one perfect score finishing, E. L. Leinbach, of Philadelphia, with a Stoddard-Dayton, winning the trophy for this class.

The contest committee has decided to award medals and diplomas to the four winning cars in the touring class and then have their names engraved on the cups. These four entrants will be eligible to compete in next year's run, and the car finish-

ing with the nearest perfect score will receive the cup. The same cars will be contestants for other cups to be offered.

Rain fell during the entire day, and many of the clean scores of Monday's run to York were wiped out before the first control at Gettysburg was reached. There were many jokers on the route, the first being a forty-mile run over poor roads from York to Gettysburg in two hours. There were no serious accidents during the entire run, but many cars were badly damaged.

The club committee which handled the affair so successfully consisted of R. C. Halderman, chairman; W. R. Douglas, secretary and treasurer; C. C. Cumber, Andrew Redmond, S. K. Hamburger, George G. McFarland, and E. G. Irvin. The officials included E. C. Johnson, of Philadelphia, as referee; C. A. Woolson, another Philadelphian, as starter, and R. H. Johnston, of New York, as pilot.

The Philadelphia *Inquirer* to-morrow will make this comment: "There were several brilliant features of the last day's run, notably the performance of Walter C. White. He drove the best race, speaking from a conservative touring standpoint, of any man in the contest, reaching controls just a few moments before his car was due. The 'race bug' developed in many of the contestants, but Mr. White did not seem to mind how many cars passed him. It was the 'cut loose' policy of many drivers Monday, when the run was absolutely easy, that killed off their chances to-day. Mr. White's run should prove a lesson to them.

"As an automobile education to the people of the towns through which the run passed the event was most successful. Everywhere the cars were greeted with cheers and flags. A notable sight was the number of horses brought along the roads by farmers who wished to make them familiar with the machines. Every courtesy was extended by the farmers, and the caution with which cars were driven when a frightened horse was encountered left a most pleasant impression."

A. A. JONES, THE FORD ENTRANT, HAD TIRE TROUBLE.

H. A. GRANT, ONE OF THE MAXWELL PARTICIPANTS.

OIL BAFFLE PLATES USED IN THE AIR-COOLED FRANKLIN.

IMPROVED LUBRICATION OF FRANKLIN MOTORS.

Three years have now elapsed since the adoption of the auxiliary exhaust which is a feature of the Franklin air-cooled motors, and the hundreds of cars fitted with it that have been in daily use during that period show that it effectively accomplishes the design of its inventor—that of increasing the efficiency of the engine and rendering its cooling certain under the most adverse conditions possible. It has been found to have one slight drawback, however, owing to the fact that it is situated on what may be termed the non-working side of the motor—that is, the side of the cylinders that only receives the stress of the compression stroke, which is very light as compared with that of the explosion stroke. It will be apparent that with the splash system of lubrication, the oil is always thrown to the non-working side of the cylinder, and must work its way round to the other side, and as the Franklin auxiliary-exhaust is on the former, it was found that some of the oil was wasted by being discharged through it. This was particularly the case when there was an excess of oil.

To overcome this a very simple device has been evolved, and it not only does away with the objection in question, but renders the lubrication as a whole far more effective. It is termed an oil baffle-plate, and, as will be seen from the accompanying photograph of a dismounted Franklin motor, it consists of nothing more or less than a light steel stamping through which the connecting rod works. It prevents the oil from being splashed on the side of the cylinder that carries the auxiliary exhaust port and causes the greater part of the oil to be thrown against the

working side of the cylinder. Another advantage is to be found in the fact that it permits of a much higher level of oil in the crankcase, thus providing better lubrication for the big ends of the connecting rods, and maintaining a larger supply in reserve in case of the failure of the oil pump. Nor does this excess of oil mean smoking and carbonization, as is usually the case, as only a certain amount is permitted to enter the cylinder.

NEW JERSEY NOW EMPLOYS A SLEUTH CAR.

TRENTON, N. J., May 7.—State Automobile Commissioner Smith to-day placed in service a high-speed auto, and inspectors will tour the State in the machine to chase speed violators. To prevent watchers from spotting the sleuth car and giving an alarm, the color and number of the State machine will frequently be changed.

Governor Stokes has not yet signed the bill appropriating \$5,500 for the machine, and there is considerable adverse comment because of the premature purchase.

OLDSMOBILES TO HAVE A HOLIDAY REUNION.

General John T. Cutting, New York agent of the Oldsmobile, announces that there will be a reunion of Oldsmobilers at the Empire City track, Yonkers, N. Y., on Decoration Day. The parade will start from the company's Broadway store at 10 A.M., and luncheon will be served on arrival at the Empire track. A drawing for a \$2,750 Oldsmobile touring car will take place, and all Oldsmobile owners participating in the parade will be eligible, with Oldsmobile selling agents or representatives barred. However, it will be necessary for participants to fill out a card supplied by the Oldsmobile Company, of New York, giving number of engine and type and filing same before May 28.

NEW TYPE RUNABOUT FROM STEARNS FACTORY.

The latest product of the F. B. Stearns factory at Cleveland, O., is an attractive four-passenger runabout, an illustration of which is given herewith. The chassis construction is the same as is used in the firm's standard runabout, but the body is novel and interesting and calculated to attract considerable attention. It has seating capacity for four people with tonneau attached, but can be converted into a two-passenger runabout by the removal of the tonneau. It is constructed with a very rigid oak frame covered with sheet aluminum, and the upholstery is a dull black waterproof leather without tufting. Operator's seat is placed six inches ahead of the passenger's seat, in order there may be no interference with the operations of the driver. The weight of the car is distributed at the center of the frame, giving exceptional riding qualities and making the steering easy.

THE LATEST INNOVATION IN HIGH-POWERED RUNABOUTS—THE STEARNS FOUR-SEATER.

THE MAXWELL COMMERCIAL DELIVERY CAR.

IMPORTERS' EXHIBITION IN THE GARDEN.

There will be three automobile shows in New York next season. The Importers' Automobile Society, which only came into being last month, has ceased to exist, its promoters having decided to throw in their lot with the older Importers' Automobile Salon and aid them in holding an automobile show for foreign machines only in Madison Square Garden, presumably towards the end and perhaps the last week of the year. The decision was arrived at on Monday at a meeting in the club-rooms of the A. C. A. under the chairmanship of Gaston Rheims.

Those who have subscribed to the action are André Massenat (Panhard), Gaston Rheims (C. G. V.), Paul de la Chesnaye (Zust), W. H. Barnard (Pilain and Delahaye), Alexander Thakara (Westinghouse), E. Lillie (Itala), Paul Lacroix (Renault), Percy Owen (Bianchi), Emile Bloch (Motobloc), E. B. Gallaher (Brasier), Wm. Walker (La Buire). It is announced in addition that three or four other firms that were not able to attend the meeting will act in accordance with the firms above mentioned and would forward application at once for membership in the Importers' Automobile Salon.

"All members of the Salon," said E. R. Hollander to THE AUTOMOBILE representative, "will exhibit at the foreign show, and will take part in no other event. Doubtless a number of the smaller importers will join us—all will be accepted on a basis of equality—and we are certain of the finest display of foreign machines that New York has ever seen. It appeared to us that it was useless to form another importers' association when one had already been in existence for four years."

A DAY'S DELIVERY OF PEERLESS RUNABOUTS.

The picture shows the cars ready for delivery to customers from the New York City branch of the Peerless Motor Car Company.

MARSH RIM PLANT TO BE LOCATED AT AKRON.

AKRON, O., May 6.—The Marsh rim plant will be moved from Columbus to Akron as soon as enough stock ahead can be accumulated to permit the manufacturing to be discontinued long enough for the change. Nearly 15,000 sets of Marsh rims have been made by the Diamond Rubber Company for the present season, and increased facilities are necessary, which explains the removal from Columbus, where the rim is being manufactured in the works formerly known as the Bryant Steel Wheel and Rim Company.

ASSOCIATION TO CONDUCT TRACK MEETS.

The United States Motor Racing Association has been incorporated in New York State with a \$5,000 capitalization. Joseph N. Gaites, William H. Pickens, Fred T. Bailey and W. H. Oviatt are named as the incorporators. The first meet of a series in various parts of the country is scheduled for the Point Breeze track, Philadelphia, May 24 and 25, a 24-hour race for fully equipped touring cars and touring runabouts to be the feature. The meets will be conducted under the rules and sanction of the A. A. A.

NEW ROYAL FACTORY NOW BUILDING AT CLEVELAND.

The view shows the progress being made on the main factory on Gordon Park boulevard. The Royal Motor Car Company expects to have it in operation by the middle of the summer. This will add substantially to the already large equipment of this company.

ALL FORD INTERESTS TO BE UNDER ONE ROOF.

DETROIT, MICH., May 6.—The Ford Motor Company has purchased the entire assets of the Ford Manufacturing Company, located on Bellevue avenue. The latter concern was organized in November, 1905, and incorporated for the purpose of making under contract motors, transmissions, axles and other parts of the Ford runabout. Recently this plant had been held under lease, and its location about four miles from the Ford Motor Company's factory caused considerable inconvenience. With the absorbing of the younger by the older concern, there will come the beginning of a huge plant on the Highland Park property, consisting of sixty acres, recently purchased by the Ford Motor Company. Henry Ford contemplates the building of the largest automobile factory in the world, and in the financing of the plan James Couzens, secretary and treasurer of the company, is entitled to great credit for his share in this undertaking, as well as in the general conduct of Ford finances.

MORGAN MAY RUN MEET ON GALVESTON BEACH.

GALVESTON, TEX., May 4.—W. J. Morgan, the well-known promoter of automobile race meets and hill climbs, has been in Galveston for the past week conferring with representatives of the Galveston Automobile Club and the Business League. The proposition of conducting a January meet on the Galveston beach was presented and is now under consideration. Mr. Morgan is now on the way back to New York on the steamer *Denver*.

BRIEF ITEMS OF NEWS AND TRADE MISCELLANY

The St. Louis Automobile Manufacturers' and Dealers' Association has decided to hold a show from December 14 to 21.

President Asa Paine, of the Minneapolis Automobile Club, has placed his order for a Winton Model M. Mr. Paine has been a Winton devotee for several years.

Work on the big plant of the Maxwell-Briscoe Motor Company at Newcastle, Ind., has been begun, the first of the steel girders to compose the framework of many tons being raised last week.

Messrs. Pirelli, who have recently opened an American agency at 296 Broadway, New York, state that Pirelli tires will be used on the Itala car entered in the Pekin-Paris automobile competition.

The Waterloo Automobile and Supply Company, Waterloo, Ia., has purchased the business of the William Galloway Company, that city, and will conduct an enlarged garage business in connection.

The T. Alton Bemus Company, Inc., of Boston, makers of the Bemus twin-ball timer, is now located in its new quarters at 358 Atlantic avenue, having recently removed from 133 Oliver street.

In the May 2 issue of *THE AUTOMOBILE* a typographical error occurred in the advertisement of the Dolson Automobile Co., Charlotte, Mich. The wheel specifications of the Dolson "Cannon Ball" should read 36x4 1-2 inches.

The Bridgeport Vehicle Company, of Bridgeport, Conn., has recently made deliveries of special limousine bodies to N. W. Bishop and E. G. Burnham, of Bridgeport, Conn. The company makes a specialty of high-class limousine bodies.

E. F. Dean, M. D., the owner of a Model E Mitchell car, recently covered 123 miles on twelve gallons of gasoline. The run was done under ordinary conditions of the doctor's practice, with the stopping and starting it entailed, the distance being recorded by a Jones Speedometer.

Organization has been completed of the Morris Manufacturing Company, at Omaha, Neb., with a capital of \$200,000, to construct resilient wheels under the patent of J. H. Morris. Organizers of the company are C. A. Sweet, John M. Dougherty and William J. Coad.

At the automobile exhibition which recently took place at the Agricultural Hall in London, England, Continental tires were on 35 per cent. of the cars exhibited; the nearest competitor was fitted to 29 per cent.; another pneumatic tire showed on 9 per cent., and fourteen other tires completed the equipment of the rest.

A 40-horsepower Lozier will be entered in the sealed bonnet contest next month by the Lozier Motor Company. This car will be one of the regular stock cars which has been run over three thousand miles this season. This decision is in line with the policy of the Lozier Motor Company to enter all contests for stock cars promoted by the A. A. A. or A. C. A.

The new Viking car, mentioned in the April 25 issue of *THE AUTOMOBILE*, sells for \$2,500, and not \$3,000, as was erroneously stated. According to A. R. Bangs, of Boston, maker of the Viking, the car, which is of 40 horsepower and has a 120-inch wheelbase, was designed to sell at

\$2,500, and the first ones have been disposed of at this figure.

The Thomas B. Jeffery Company has shipped from the Rambler factory at Kenosha, 7,500 enameled metal signs to put up warnings to motorists on highways in all parts of the United States. The signs are sent in batches to Rambler agents, with instructions to properly letter them, giving necessary information to tourists, and to place them in position without delay.

The Waltham Manufacturing Company has secured the services of Dr. A. D. Hard, of Marshall, Minn., to demonstrate its friction drive buckboard to the physicians of the Northwest at the State medical societies this summer. Dr. Hard is an automobile enthusiast and has the name of being the first physician west of the Mississippi river to use an automobile in country practice.

Automobiles will soon be supplanting sledges and dogs in the far North, judging by a news item from Alberta, Canada, stating that nine motor cars, with more ordered, are now surprising the natives on that far Canadian frontier. According to a *Medicine Hat* journal, eight Maxwells are in commission in that town of 4,000 population, or one for every five hundred inhabitants.

Elwood Haynes, the designer and manufacturer of Haynes automobiles, has calculated that the impact of a touring car striking an immovable object at sixty miles an hour is equal to the shock it would receive if it fell from the top of a skyscraper. The shock given to the mechanism of an automobile with the ordinary clash gears when a careless change is made from the high at thirty miles an hour to the middle gear at fifteen miles an hour, is equal to the impact that the car would sustain by a vertical fall of seven feet.

That the Automobile Club of Buffalo will make an effort to retain the Glidden trophy this year is shown by the fact that a team to represent that organization has already been promised by its members. Four cars are certain to be entered, and several more may be added to the assured entries before the tour starts. The first Buffalo entry has already been made by George S. Salzman. He will drive a Thomas Flyer of 60 horsepower. Although not superstitious, Salzman was rather gratified to find that his car will be numbered 9. Last year he drove a Thomas Flyer through the Glidden tour with a perfect score, and then, as it will be this year, his car bore a big "9" on the radiator.

NEW AGENCIES ESTABLISHED.

The LaGrange Automobile Company, LaGrange, Ga., recently organized, has been appointed local agent for the Reo.

The Philadelphia Motor Car Company, with salesroom and garage at 236 North Broad street, that city, has been appointed agent for the Frayer-Miller.

The Sweeney & Nail Auto Co., 59-61 Court street, Brooklyn, N. Y., has secured the Greater New York agency for the Kissel-Kar made at Hartford, Wis.

The Aerocar Company, of Detroit, has established the following new agencies: A. D. Rivers & Co., Toledo, O.; H. A. Harmon, Portland, Me., and the American Auto Company, Cleveland, O.

The Reimers' Motor Company, Louisville, Ky., has been organized with salesrooms at Baxter avenue and Broadway, that city. The company will sell the Logan, Gale, Aurora and C. S. lines.

Boston has another new agency, the Puritan Motor Company, which has established headquarters at 43 Columbus avenue, in the Park Square auto station. The company is agent for the Dolson and the Mason.

PERSONAL TRADE MENTION.

Charles Schmidt, designer of the Peerless Motor Car Company, who has been spending the past six weeks in Europe, has returned home, arriving in New York last week.

A. W. Robbins, New York manager of the Aerocar Company, last week visited Washington and placed an Aerocar agency with J. B. Maxwell, 829 Fourteenth street, N. W.

L. H. Perlman, New York representative of the Welch Motor Car Company, entertained a score of personal friends at the closing dinner of the Pleiades Club, at the Hotel Astor, last Sunday evening.

J. R. Jamison, formerly connected with the Pope Motor Car Company, has joined the selling force of the Aerocar Company, of Detroit, as has also W. H. Howe, who has been associated with the Chicago branch of the Corbin Motor Vehicle Company.

RUSHMORE LAMPS ABROAD.

Rushmore Lamps, Limited, is the title of the English branch of the Rushmore Dynamo Works, of Jersey City, N. J., and the establishment at 49 Rupert street, Shaftesbury avenue, W., London, gives ample evidence of the favor with which these American lamps have been received abroad.

RUSHMORE LAMPS' ENGLISH BRANCH.

Their prompt acceptance on the other side is apparent from the fact that they have already been adopted as the standard equipment of all Fiat cars in England, India and the Colonies; they are carried in stock by the agents of such prominent cars as the Panhard, Isotta-Fraschini, Martini, Mer-

cedes and Wolseley, and are supplied on numerous orders. Rushmore agencies have recently been established in Berlin and Milan and the excellence of the lamps is probably most strongly attested to by the fact that Continental manufacturers are making haste to copy them. At the recent Agricultural Hall show in London, the sole American accessories exhibited are said to have consisted of a few brands of lubricating oils and the Rushmore lamps. They are used by royalty and many of the lesser lights of the nobility both in England and the Colonies.

INFORMATION FOR AUTO USERS.

New and Ingenious Accessories.—At a time when every automobilist is casting his eye over his machine and wondering what additions he needs to his outfit for the coming season, it is opportune to call attention to some of the new and useful instruments handled by the Auto Supply Co., 1733-1737 Broadway, New

York. The compressor is a little instrument which will tell accurately the compression of the cylinders. The illustration shows the nature of the apparatus, which has simply to be screwed into the place of the spark plug. On turning the motor over slowly by hand, the compression is registered accurately on the dial. Nothing simpler could be imagined,

BROWN COMPRESSOMETER

and there is a degree of accuracy altogether unattainable by any of the older expedients.

Timing the ignition or firing point of a motor is a delicate operation, but one that must be performed if good results are to be obtained. The instrument is placed on the top of the cylinder and the metal rod passed through the compression cock. The position of the piston is indicated with accuracy by a movable stop on the rod at each side of the scale. One side of the scale is marked with English, the other side has metric measurements. The rod is eighteen inches long and the scale six inches, or 150 mm., in length. For measuring the stroke of pistons the instrument is particularly handy. Its method of use is obvious.

DEVICE FOR TIMING FIRING POINT

The good features of the flexible valve remover are its simplicity and the ease with which it can be operated in inaccessible positions. It would be difficult to imagine anything more simple: a U-shaped piece of metal with a chain attached, and a lever bar with two or three double slots bored through it. One end of the slot allows the chain to pass easily, the other side holds the links prisoner.

Smooth-On is a preparation not entirely new to the mechanical world, but one that has not previously entered into the

domain of the automobilist. It is a cement of chemical iron compounds that withstand fire, water, gasoline, steam or oil. When hard it becomes a metallic iron that expands and contracts the same as iron. Its chief use is for repairing cracks in a water jacket or leaky radiators. The defective part is first cleaned and the crack and surrounding metal are heated either by running the engine or by a gasoline torch, and while the metal is hot the cement is applied. If the defective part has been sufficiently heated the cement will run into the opening and harden rapidly. When hardened it possesses the properties of iron and can be smoothed up with a file.

Another very useful article consists of a pair of universal shears with which it is possible to cut any diameter circle or angle as easily as along straight lines. It is particularly handy in making gaskets, shimming brasses, etc.

Flexible Steel Armor for Tires.—The Kimball Tire Case Company, of Council Bluffs, Iowa, which has been making steel tire armor to fit ordinary automobile tires for the last two years, has brought out a new design for covering Dunlop or Good-year tires. The accompanying cut shows

KIMBALL STEEL TIRE ARMOR.

the manner in which a steel covering is attached to a quick detachable tire. The rings into which the clasps hook are curved in such a way that they fit tight between tire and other ring which are with the rims of that class and when tire is removed the armor stays on. Tire and inner tube can be changed the same as it can without the armor. When tire is in place on wheel there cannot be a blowout or rim cut no matter how rotten the tire is.

Triumph Magnetic Gage.—A magnetic gage which keeps a record of the gasoline put into and removed from a tank has been produced by the Boston Auto Gage Company, 14 Old South Building, Boston, Mass. It consists of a tube depending from a head that may be screwed into a bushing connected with the tank. On the under side of the head is a chamber in which is located a magnet rotatable above the end plate at the upper end of the tube, the magnet having suspended from it a ribbon shaft of rustless material embraced by a float metal that turns the ribbon and magnet more or less according to the quantity of gasoline in the tank. The head is chambered at the top to receive a small needle carrier

or compass box shown detached in the small figure at the right. This box has a dial and the needle is held in alignment with the magnet, indicating the

TRIUMPH MAGNETIC GAGE

amount of gasoline in the tank. This feature, in itself, is a very useful one, and gives excellent satisfaction to users of this gage. When the car is left, the compass box can be removed from the top of the gage and carried away in the pocket. The magnet needle is then automatically locked in position. When the box is again put on the gage it immediately unlocks the magnetic needle, and if any change has been made in the quantity of gasoline the difference will be at once indicated.

Moon Roller Bearing, Apex Friction Brakes.—By the scientific application of several well-known principles, the Moon Brake Company, Third and Porter streets, Detroit, Mich., have evolved a simple and compact type of brake for which much is claimed. The essentials of the device will be plain at a glance at the accompanying illustration of it. The apex formation provides nearly three times as much friction surface as a flat band or drum. The friction is caused by a quadruple eccentric, the power again being doubled by an eccentric within an eccentric, producing a far greater leverage than can possibly be obtained by means of single cams or link motion. The entire brake is enclosed by a dust-proof housing and runs in grease.

MOON APEX FRICTION BRAKE.

It may be applied as little or as much as desired, and can either be locked or released instantaneously. The makers claim that a set of Moon brake shoes will outlive any car made. A Winton car fitted with the Moon brake is used in Detroit for demonstrating.

The Pope Manufacturing Company, Hartford, Conn., has just sent forth the 1907 edition of its accessories catalogue, containing in about seventy pages a very complete description of automobile accessories and parts of both foreign and domestic manufacture.

THE AUTOMOBILE

PREAMBLE.

“LE CIRCUIT,” how to get there, and how to get away again, has been the problem with enthusiastic autoists in France ever since great “events” were inaugurated.

There is absolutely no question but that the Circuit de Normandie, the venue of the French Grand Prix for 1907, is the most accessible—to automobilists—ever known. Practically it is within easy distance of Paris, for what is the 180 kilometers from Paris to Dieppe once one is free of the dozen or twenty execrable suburban pavé via St. Germain or Pontoise. It’s bad enough either way; whichever route one takes, he wishes he had been wise enough to take the other.

Besides this the “triangle is within a half hour’s or hour’s journey by road of a dozen small and large provincial towns and cities where may be found all the accommodation that man and his modern beast of burden, the automobile, require. To be sure, one does not get *vin compris* at the tables d’hote of the inns of the small towns very often; it is the *pays du cidre*, Normandy, and the great yellow globes or carafes of cider are quite as refreshing on a hot summer’s day as wine; and *Calvados*—which is a Frenchman’s way of naming “apple-jack”—is quite as fortifying as *cognac* itself.

The accompanying sketch map and tables tell the story of accessibility and accommodation better than mere rhetoric, and so they are allowed to stand for themselves.

Rouen, Le Havre, or Dieppe are the nearest at hand, but, of course, for the great event they will be overrun for days by all sorts and conditions of men and automobiles. This, perhaps, will also be true of Fécamp, Yvetot, and Tréport, but the reverse is likely to be true of Abbeville, 30 kilometers from the northeasterly corner of the course; and Les Andelys, Gournay, or Gisors, between Rouen and Paris; or Honfleur, Louviers, or Pont de l’Arch, all of them

but from 50 to a 100 kilometers away from the scene of the race.

Coming from abroad via Dieppe, Cherbourg, Le Havre, or Boulogne, the course is readily arrived at by the roads as marked, and there is much evidence to suppose that a larger number of Americans than ever before will be present at the great French race, especially with the indomitable and persistent Christie numbered among the participants. Governmental, departmental and municipal appropriations have been made with a free hand towards the re-making of the roadway, straightening of bad curves, and even of cutting down dangerous abutting trees. Grandstand accommodations of a superior and exceedingly luxurious order have been planned, restaurants and cafés projected, and telegraphic and post-office facilities promise something phenomenal.

Enthusiasm—and the French are extravagantly enthusiastic, as we who know them best must admit—may exaggerate somewhat, but the fact is the course is admirably placed and in point of fact the best France has ever had, midway between the “Circuit d’Auvergne,” which was too mountainous, and the “Circuit de la Sarthe,” which was too monotonously flat.

HOW TO TOUR NORMANDY.

Normandy, Brittany, and Touraine are the ideal automobile touring grounds in France, if not in all the world. The stranger automobilist usually arrives in France via Cherbourg, Le Havre, Dieppe, or Boulogne. In either case he “tumbles” immediately into Normandy, as the French say. Most likely he makes wheel tracks for Paris at once, though he makes a mistake when he does it. Anyway, the round of Norman towns, as one approaches the southern boundary, comes very near to Paris, so the present itinerary takes the gay capital as the starting point. The way out from Paris, via the Route de

AT THE TRAPPIST MONASTERY.

Quarante Sous and Mantes, is through St. Germain. It's a shockingly bad bit of roadway all the way to St. Germain, 20 kilometers and mostly *pavé*, but it's unavoidable unless one goes via St. Denis and Pontoise, and then it is 25 kilometers and *all pavé*, and after Pontoise a long stretch of still worse cobblestones. The road by St. Germain and Mantes is by far the better.

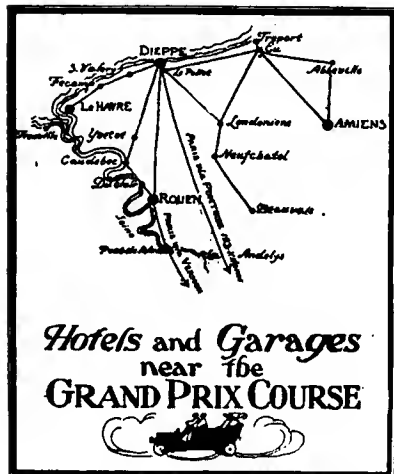

St. Germain is lovely, its château, its terrace, and its Forêt, but the town is a dirty hole, difficult to navigate with an automobile and possessed of a pirate crew of octroi officials who stop you at the barrier and would look for smuggled spirits into the barrel of your tire pump, if the idea only occurred to them.

Up and down hill and dale, with delightful prospects of the Seine Valley on the right, the great Route Nationale, No. 190—*Paris-Rouen-Le Havre*—runs for 30 kilometers to Mantes. Mantes has the votive church of Notre Dame, built, or endowed, by William the Conqueror. Practically it is a copy, as to its façade, of Notre Dame at Paris. This is all Mantes has to offer as a "sight" save the river and its bridges, and its hotels are abominable for a French town of its size. So, too, they are at Vernon, 25 kilometers further on. Don't think of stopping for lunch short of Les Andelys or Pont de l'Arch.

A French Town which Has an Auto Trap.

Between Mantes and Vernon is Rosny, with the natal château of Sully, the minister of Henri Quatre, and a little known painting by Corot in the parish church. Nearby is Moisson, and it will be an off-day if a Lebaudy "airship" isn't having a try-out in the heavens above. It is worth looking out for.

Beware of Bonnières, a half dozen kilometers further on. The

maire has posted a notice at each end of the village cutting down the speed limit to six kilometers an hour—(figure that out in miles, say three and a half, and just think what that means when, "all out," you can do an average forty). Many an automobilist, French and stranger alike, has paid the penalty here for non-observation of this warning.

Vernon is a delightfully situated Seine-side town, and turning to the

left, up the hill and through the Forêt de Bizy, is a detour of fifty or sixty miles, including Pacy-sur-Eure, Evreux, and its cathedral, and Conches, each and all of them typical Norman towns. If this detour is made, lunch either at Pacy-sur-Eure, Hotel de Lion d'Or, or at Conches at the Croix Blanche. At either you eat of the best of the Norman countryside, good beef, mutton and vegetables, and never *jambon aux œufs*, with which the hotels of the big towns regale Anglo-Saxons as a *plat special*. Curious that they size up the appetites of the English-speaking traveler as based only on *ham* or *bifteck*.

Then there are the cheeses in Normandy, too many in kind to enumerate, but always le Camembert, and sometimes Pont Salut, the best cheese in France, save, perhaps, the "fromage bleu" of Rochefort, too strong for some.

From Vernon the road by the Seine, still Route Nationale No. 190, goes straight on for 14 kilometers to the famous Côte de Gaillon, the scene of a yearly "hill climb" famous in the annals of automobilism since long years.

Une Colonie Americaine.

From Gaillon, or from Vernon if you like, cross the Seine to the right bank. Opposite Vernon is Giverny—*une colonie Americaine*, the habitant calls it, for there are anywhere from a dozen to fifty Americans there the year round, mostly artists. Years ago Madame Bodet, who ran a little grocer's shop, took a couple of American artist fellows to board—for a price so ridiculously low that one dares not mention it now—and in time a hotel grew up with an added wing every year, until to-day one may find two score of men and women—always Americans, or if not always nearly always—all painting away as if Giverny and its surroundings were the only paintable spots in France. Madame Bodet, the elder, has retired into the background and a young Madame Bodet, the wife of Gaston, who comes from Paris, has taken her place. All is lovely as of yore, but prices have gone up at the Hotel Bodet.

Down river twenty kilometers, always by that same delightful Route Départementale, is Petit Andelys, snug lying beneath the famous Château Gaillard, Richard Cœur de Lion's "Saucy Castle," built, so says tradition, in a year. The ruin of the once proud old castle is still there, on a monticule rising 300 feet or more from the river's edge. On the waterside is the Hotel Bellevue, the most delightfully situated and altogether most charming hotel between Paris and the sea. It has an inner courtyard, vine-covered and tree-shaded, and when a half dozen automobiles and their attendant paraphernalia don't fill it to suffocation one dines out in the open under the trees, and after strolls on the river bank or up to the château in the moonlight and thinks nothing were quite so idyllic in these rush-about twentieth century days.

The Hotel Bellevue is very, very good, indeed, but it is the ensemble that makes it so. The proud old aristocratic patron, Thiriet, has his own notions about what you ought to eat and how it ought to be cooked, and you eat it that way or not at all, but it's thoroughly good in quality and bountiful in quantity, and there is no *garlic* in it. You drink cider, of course, and not wine, but the *patron* makes it himself, not by squeezing the apples in a press—that's the common peasant's way, he tells you—but by simply crushing them and pouring tepid water over them and letting it run off into barrels. Eight days after it's ready to drink. Simple, isn't it!

As to who discovered Petit Andelys and Château Gaillard is in doubt. Sir Walter Scott knew it and Cotman and Turner painted it, and a dozen or fifteen years ago a yachting, coaching (and in these days automobiling) millionaire (for he is still faithful to Les Andelys and Thiriet, and turns up regularly at least once a year) came along and gave it the cachet of his favor and did some booming of it in a mild way among his friends, and so established the town as a place out of the ordinary and easily the finest place on the Seine.

Between Les Andelys and Rouen is Pont de l'Arch with a good hotel, too (Normandie), and twenty kilometers to the west

is Louviers, with the most wonderfully flamboyant Gothic church extant and a good hotel, the Mouton d'Argent.

Where to Dine in Rouen.

Rouen, of Jeanne d'Arc and Cathedral fame, is seventeen kilometers from Pont de l'Arch by the river road all the way.

Rouen shall have no guide-book information here; just a few words about hotels and things. There's anything one likes at Rouen in the hotel line, and in the garage line, too. The Hotel d'Angleterre on the quai, or the Hotel de la Poste on the Rue Jeanne d'Arc, are excellent establishments of the first order, with prices accordingly, but much cheaper, of course, than American prices for the same sort of thing.

For a novelty the Hotel Lisieux, on a back street running parallel with the quai, just off the Rue de la Republique, is to be recommended. There's nothing quite like it in all France. It's bourgeois, excruciatingly so, but its fare is marvellous in excellence and variety. Never has the writer seen a lay-out quite like it, and *vin* is *compris*, red or white *vin d'Algerie*, not one of the world's great *crus*, but a most pleasant drink. The déjeuner or dinner is all one's fancy will picture it, but the dessert, the sweets, the cheeses (eight or ten of these last) and the fruits will seem a dream. Go to Rouen and cut out the churches if you will, but don't miss the Hotel Lisieux. You will have to garage your machine at Adrien Menager's, near by, and that will cost you a franc, whereas otherwise you might get it sheltered free—but that's a mere nothing.

From Rouen to Caudebec-en-Caux is 35 kilometers, via Jumièges and Duclair. Jumièges is a grim, old ruined Norman abbey which, seen by moonlight, awakens the same emotions as those claimed for the Coliseum and Melrose. Duclair is a market town and not much more. Caudebec, 15 kilometers further on, should be included in every Norman itinerary, particularly if the "mascaret" is on. The "mascaret" is a great incoming wall of water which rushes up the Seine at certain seasons of the year at an alarming rate. It is a veritable whirlpool and a sight worth coming miles to see, but it's all over in a minute.

Dieppe Has Many Attractions.

Dieppe and its attractions are known to all. At Puys, on the cliff just eastward of Dieppe, may be seen the house where Dumas père lived and died. At the easterly end is Eu and its now ruined château, and Tréport, the Parisian watering place—not fashionable, but the *vogue*, nevertheless.

Fécamp to the westward, but still 40 kilometers from Havre, has a history and an industry. The industry, or more correctly

the produce of the industry, is better known than the history; the "Benedictine Brewery," as a German contemptuously referred to it in one of those brief intervals when Germans travel in France, is one of the "sights" of the town, and a very interesting sight it is. You get a free drink besides. *Verb sap!*

Étretat and its *falaises* are known to all who remember or have ever seen the "Table Books of Art" of a half century ago. Étretat was the chief artists' sketching ground in France after Barbizon, in the days of Louis Philippe. Étretat's *vogue* has passed and the automobilist rushes in and out like a glance of

THE FINEST TOWN IN NORMANDY: PETIT ANDELYS.

the eye and goes to St. Jouin for déjeuner—if he knows his business. St. Jouin has got the real thing in the way of a hotel, the Hotel de Paris, "conducted," as one learns formally, by Madame Ernestine Aubourg. In the days of Dumas Père, when the inn was already famous, she was simply "La Belle Ernestine" and M. Aubourg had not then appeared on the scene. Dumas described "La Belle Ernestine" in 1865.

How One Crosses the Seine.

To pass the Seine one has to double back from Le Havre to Lillebonne, 35 kilometers, via Harfleur and Tancarville, keeping always by the river road and not going by the island route via Bolbac, as most do. One crosses the Seine by an antediluvian *bac à vapeur* from Lillebonne to Quillebeuf, at a cost of from one to two francs, "according to the force of the motor." From Quillebeuf via a by-road one arrives, in a dozen kilometers, at Pont Audemer, an unconvincing, small, smug town of Normandy, whose principal "affaires" are those of the litigation courts.

It is a main road from Pont Audemer to Trouville, 38 kilometers via Honfleur, one of the most delightfully quaint old Norman seacoast towns existing. Trouville is the gayest, most sporty, of all the northern French *plages*. Honfleur is its antithesis. There is an admirable *corniche* route from Honfleur to Trouville, 14 kilometers along the edge of the cliff, a reminder of the Mediterranean *corniches*.

Trouville—*un petit Paris au bord de la Mer*. You get anything you like here, and are willing to pay for, at the three-starred Hotel des Roches Noires or the Hotel de Paris. Lunch at either, if you will, on a terrace overlooking the sea, and stroll about the promenades after, but dine and sleep at Pont l'Eveque, 10 kilometers inland, and see what a real French country hotel is like. Pont l'Eveque is as prominent a center for the cheese and butter trade as one finds in Normandy, and there will be a supreme satisfaction in seeing the untrammelled life of the people as contrasted with the affectations of Trouville-Deauville.

If the above proposition is not wholly agreeable, and you are going to make the Norman round as quickly as possible, you make your stopping place for the night at the Hostellerie Guillaume le Conquerant, at Dives-sur-Mer, 20 kilometers west of Trouville. The hotel is a curiosity—a musée, if you will—such as you will not find in all France. It is got up for show and is nothing indeed but a "sight," though the fare is good and the price is low, not over nine francs a day. It was from the port of Dives that William the Conqueror set sail in 1066 to revolutionize the manner of life in England—and he did it.

Mont St. Michel is the end of every Breton and Norman pilgrimage. It really belongs to Normandy, though practically it is on the boundary between the two ancient provinces. It's delightful to pass the night on the water-surrounded isle, to wake with the sun and imagine what it must once have been when the

"WHAT YOU HAVE TO PAY."

monks of the old abbey were in "peril of the sea," but the automobilist finds scant accommodation here.

The distance from Coutances to Mont St. Michel, via Granville and Avranches, is 87 kilometers. From Mont St. Michel to Mortain, 48 kilometers, or to Domfront 74. Three to five days have been spent en route up to now. One might as well thread the highways as well as the byways, and spend a month in Normandy, but most automobilists will not see it that way.

Back to Paris Through Touraine.

The itinerary can well be combined with that of Brittany by keeping on westward from Mont St. Michel and so on back to Paris through the châteaux country of Touraine, but if one turns Parisward again at Mont St. Michel he will want to spend at least two days more en route.

Argentan, Alençon and Mortagne (not Mortain this time) should be visited and *déjeuner* taken at the monastery of La Trappe, near Mortagne. If it's a stag party, one may dine simply in the refectory of the monastery itself, leaving the automobile outside in charge of a brown-robed, gray-bearded brother, whose usual occupation is minding his *très belles vaches*, or watching the bees going and coming from their hives—cheese and honey are the two great specialties of La Trappe-Soligny.

The route from Argentan or Mortagne to Paris via Laigle, Verneuil and Dreux is approximately 156 kilometers, an easy day's run, allowing a stop for lunch at Dreux (Hotel de France).

This return itinerary through Normandy comprises quite a different topographic ensemble from that out by the Seine Valley and the coast road. The soil is more rolling and, taken all in all, is a hilly stretch; nothing hard, and the surfaces always well kept, but with a typical French countryside character to it.

One might vary the return from Mortagne by entering Paris via Chartres, Maintenon and Rambouillet. Chartres and its cathedral, its excellent "commercial" hotel, the Duc de Chartres, and its altogether delightful surroundings should be omitted from no automobile itinerary which comprehends Normandy, Brittany or Touraine. It can be readily combined with each.

In the Country of the Vine.

It is 18 kilometers from Chartres to Maintenon—and here, by the way, one is in the *pays du vin*; wine takes the place of cider at table d'hôte simply because it is a vine-growing country instead of an apple-growing one. Maintenon is a pompous little town of 1,400 inhabitants, and is marked in the French road books with a miniature locomotive, sealed letter and a telegraph pole, indicating that it is a railway station, a post-office and a telegraph office. One of these excellent French road books, the Guide-Michelin, goes so far as to give a miniature reproduction of a red cross flag, indicating that the badly injured may be properly taken care of, by local aid. Automobilists don't get so seriously injured in these days as they did at first, and they don't so often injure others, but all the same it's good information to give in a guide book, and in this respect the French lead the world—even the indefatigable Germans. Maintenon's interest for the traveler is in its associations of the widow Scarron, who, as the Marquise de Maintenon, married Louis XIV in 1684. Louis XV came along in turn and built a château for "La Pompadour" here, but it has disappeared to-day.

Maintenon to Rambouillet is 22 kilometers, and three kilometers of it through the town are as bad an example of *pavé* as one meets in a thousand kilometers of French travel. Here is the state château de Rambouillet. It was acquired for the crown by Louis XVI in 1665 and is still occupied for the hunting by the *bons bourgeois*, the presidents of the present republic.

The roads through the Forêt are excellent and a charming détour of a dozen kilometers can be made. Paris is entered in either case through Versailles, but if one is going north again within a reasonable time, or even down into the Fontainebleau region he can find admirable garage accommodation at Versailles and save a dozen or twenty miles of nerve-racking automobiling each way to and from the center of Paris.

Auto Organizations After the Hotels.

The Touring Club de France, and the Automobile Club de France are doing their utmost to brace up provincial hotels, and in Normandy the seed of their efforts is taking root. "*W. C.'s perfectionnés*" are springing up like mushrooms where a *lieux* only formerly existed. The sleeping rooms, too, are being refitted on the "*hygiénique*" plan here and there, and you know what you are paying for each separate thing from the posted notices.

The road signs, the " *poteaux indicateurs*," throughout Normandy are excellent and may be read whilst moving at a swift pace. This the automobilist will like, though the propriety may be doubtful. Coming out from Paris, and indeed on all the main roads, the signs are particularly legible. They give first the name of the Route Nationale, as—Paris-Le Havre—with the distance from Paris and the distance to Le Havre. Then the distance to the next nearest town in either direction. No elaborate formula or hieroglyphics to remember or forget. The road signs of France are a blessing.

Essence and *huile*, which is the Frenchman's way of naming gasoline and oil, are obtainable everywhere, the former selling for two francs to two francs fifty for five liters, something over a gallon; more expensive than in America, of course, but a small factor when touring. Each is obtainable everywhere.

A TYPICAL STRETCH OF AVERAGE COUNTRY ROAD NEAR WATERLOO, INDIANA—IT MUST HAVE BEEN WASH-DAY ON THIS FARM.

LAYING OUT THE ROUTE FOR THE BIG TOUR

By F. ED. SPOONER.

COLUMBUS, O., May 19.—Columbus is possible in a day's run from Indianapolis, and Indianapolis is possible in a day's run from South Bend. The two hardest portions of the trip of the "Pathfinders" in their great six-cylinder, 70-horse-power Pierce-Arrow car have been completed successfully, and, what is more, after hard storms, and the long journeys have been found not impossible.

The "Pathfinders" arrived in Columbus, Saturday night, after traveling 174.4 from Indianapolis, nearly 25 miles shorter than the estimated distance. This long journey was made after two days of hard rain, and yet the long, straight stretches of road from Indianapolis to Dayton, over the National Highway for a great part of the distance, and from Dayton to Columbus, were found possible. The road from Indianapolis is straight away, and cannot be lost. From Columbus to Springfield is again a long, straight stretch, and from Springfield to Columbus, another. The turn at Springfield and one at Dayton are the only ones to be made.

In good Summer weather, with the roads dry, this route will compare with any in the country, and from thirty to forty miles an hour as an average would be possible. The tourists

will not make this, as they are to have a pacemaker twenty minutes ahead, and the pacemaker will keep the pace at legal speed. Beyond him a contestant cannot go under any circumstances, for should he do so it will mean disqualification.

With the completion of the trip to Columbus the entire route of the Fourth Annual A. A. A. Tour becomes known. The cars numbering from 1 to 200, with from five to six hundred people, will leave Cleveland, July 10, and proceed over the well-known route through Elyria and Norwalk to Toledo, a distance of 121 miles. At Toledo, as at Cleveland, ample accommodations for man and machine will be found.

July 11 the trip will be from Toledo to South Bend, a distance of 166 miles, a long day's run, but one which will be made easily in good weather, and with, perhaps, a little difficulty in bad going. The big Pierce averaged easily twenty miles an hour with frequent stops for pictures and for information at each town and on the road.

From South Bend, July 12, and returning to South Bend, July 15, the trip is 101 miles each day. South Bend provides accommodations equal to any that can be found on Broadway or elsewhere in the country.

NEAR SOUTH AMHERST, O., BEFORE THE RAIN HAD CEASED.

NEVERTHELESS OHIO HAS SOME EXCELLENT ROADS.

THE FIRST NIGHT'S STOP WILL BE IN TOLEDO.

The journey of 147 1-2 miles from South Bend through Rochester, Kokomo, and Tipton to Indianapolis had caused some speculation, but this route provides roads absolutely ideal and very interesting. In fact, all Indiana roads are good, much to the surprise of the "Pathfinders," who compare them to New Jersey and Massachusetts roads.

Indianapolis secured a place on the route at the last moment,

ELMER APPERSON TAKING THE PATHFINDERS INTO KOKOMO.

and by invitation of the city officials and the newspapers, and is so delighted with the prospects of having the tourists that it will give them a welcome second to none on the route. The cars will be parked around the National Soldiers' Monument and will be under guard of the city police.

The Indianapolis met the tourists at Tipton and escorted them in. Edgar Apperson, of Kokomo, had met them at Roches-

IN INDIANA WHERE SHEEP RAISING IS PROFITABLE.

ter and taken them to Tipton, picking out an excellent but devious road, with some nineteen turns in a few miles. The Indiana Association of the A. A. A. will place signboards at every corner in the State, from the Illinois to the Ohio border.

A blind man could follow the route from Indianapolis to Columbus, for it is straight as a die from Indianapolis through to Dayton and again straight from Dayton to Springfield, and again from that city to Columbus.

From Columbus the route will be eastward through Canton to Pittsburg, Bedford Springs (where Sunday will be spent), then Baltimore, Philadelphia, and New York. The entire route will be about 1,500 miles.

PATHFINDERS OF COLUMBUS AND PIERCE'S PATHFINDER.

The route from Chicago east by the route the "Pathfinders" are following is new to tourists, but ideal in every way. From Indianapolis to Dayton it may be changed somewhat to allow of a side trip to New Castle. Vice-President Fairbanks sent Messrs. Maxwell and Briscoe to the main line of the tour to ask the committee to make a detour of a few miles to pass through New Castle.

Thus far, and to the end, in all probability, the tourists have every facility for a good time. Good hotels everywhere promise

THE ESCORT OF THE PATHFINDERS INTO INDIANAPOLIS.

the finest accommodations, and agree in writing to keep the regular rates. Garage men promise gasoline and sign to supply it at regular rates. The roads are good all the way, and do not include tough going to any extent, and every point thus far honored by a place on the tour promises to treat the hundreds of tourists royally. Chairman F. B. Hower is a business man, and is arranging this tour on business lines, making sure of everything in writing, and taking nothing for granted.

The Pathfinding Pierce, with Dai H. Lewis, secretary of the Touring Board; Teddy Dey, driver, and F. Ed. Spooner, photographer, will continue its trip to Canton with a guide supplied by that city, to-morrow morning.

ARCHITECTURAL DESIGN FOR THE GATEWAYS.

WORK BEGUN ON PARKWAY

LONG pent-up curiosity on the part of hundreds of autoists and others interested in the Long Island Motor Parkway was finally satisfied last week when the announcement of more than half the route was made, and what was considerably more to the point—work was actually undertaken. There have been so many conflicting rumors and so many unfounded reports, particularly regarding the amount of right of way donated to the corporation that it did not come in the nature of a surprise to learn that the present western terminus of the Parkway will be Garden City instead of Floral Park, three or four miles nearer the city line, as at first given out. The Parkway will start from a point about midway between Garden City and Mineola, and will be entered from the road running almost due north and south that connects the two. From here its trend will be practically due east on a line parallel with the main line of the Long Island Railroad and a part of the Vanderbilt Cup course of 1904. For six or eight miles the land is a dead level, and there is no necessity for either a grade or a bend. After passing Hicksville, where the railroad divides for the north shore branch, the main line takes a southward trend, and the route of the Parkway does likewise to avoid it. The country continues flat throughout that portion of the route until the latter bends northward, diving under or going over the Long Island Railroad tracks between Farmingdale and Deerpark; just what it will do here and other places where there are obstructions to be avoided will depend upon the result of the surveys.

Once north of the railway line, the route strikes into what is known as the West Hills and Dix Hills section. Of course, Long Island cannot boast of anything very ambitious in the shape of a hill throughout its entire length and breadth, but this portion of the north shore extending from Cold Spring on the west to beyond Port Jefferson on the east is practically mountainous by comparison with the absolute flatness of the remainder of the island.

According to the government survey the hills vary from 200 to 300 feet above sea level, the latter being exceptions of course, and few of the roads reaching that altitude. Here, too, the Parkway will

A. R. PARDINGTON, VICE-PRESIDENT AND GENERAL MANAGER.

assume more diversity, not alone in the shape of scenery, but it will lose some of its arrow-like straightness, due both to the presence of the hills and hollows in question and to the necessity of discreetly going round the holdings of grouchy land-owners who would not give permission to go through. However, any curves will be long and easy.

Although but 35 to 40 miles from New York City, this part of the island is but thinly settled, and is about as wild as any part of Long Island can be. Cross-island roads are few and far between after leaving the pike that connects Northport on the Sound with Babylon on the south side, and which passes through Deerpark, and those that are encountered are usually in hollows so that they will have to be crossed on bridges, thus adding a bit of variety to the character of the road. For a number of miles the route will skirt the side of the ridge that forms what appears to be the backbone of the island, occasionally rising to a high part of it and affording a view of the ocean where trees do not intervene to cut it off. But the land again comes back to the same dead level that distinguishes its first stretch, a little

further along, and the speeder will get a view of not a little of that most characteristic type of Long Island vegetation, the scrub oak. The original formation of the island is also revealed in the miles of sea-sand and gravel, as the route approaches Lake Ronkonkoma, which is to be the terminus of the present stretch. This is a distance of 32 miles, almost in an air line, and it is expected that the gap between this point and Riverhead—a distance of 26 miles—will be ready for surveying long before construction is finished on the first portion. The work has been placed in charge of E. G. Williams, a Yale man, who has long been identified with railway construction both in this country and South Amer-

BEGINNING THE WORK OF SURVEYING THE ROUTE.

MAUD ADAMS' HOUSE NEAR LAKE RONKONKOMA.

A "WHITE" OBSERVER OF PICTURESQUE RONKONKOMA.

ica, and who is at present building the Washington tunnel. No decision has yet been reached as to the character of the material to be employed, but it is confidently expected that the Garden City-Lake Ronkonkoma end of the Parkway will be completed by November, though it may not be thrown open until the following spring.

POPE-TOLEDO BUILD VANDERBILT RACER.

Pope-Toledo will be again represented in the Vanderbilt Cup contest whenever that event is held. It appears that work has been progressing for some time on a special chrome nickel steel racer, all particulars regarding which are carefully withheld. It is declared that this is the most costly steel made, and that it is not only the strongest, but also the lightest and most flexible. In addition to the special racer, the Pope Motor Car Company will enter in the Vanderbilt race a type XV, 50-horsepower regular stock runabout. Herbert Lytle is reported to be the prospective driver of one of the machines.

DRAGON RACERS FOR VANDERBILT CUP.

The driver and constructor of the two racing cars being built by the Dragon Automobile Company for the Vanderbilt contest is L. Charles Kenen, a French designer of experience, who was for many years connected with prominent European factories, having been with Darracq, and for three years each with Clément and Brasier. Mr. Kenen has been at work for six months on the Dragon racers and is at present attending to the assembling of the engines, which he expects to complete about May 25. In the meantime the construction of frames and running gear for the racers is being pushed forward at the Philadelphia factory.

BRITISH AUTO RACE TRACK ALMOST READY.

LONDON, May 12.—A few weeks more and the world's first exclusive automobile race track will be thrown open for public displays of speed. July 16 has been fixed as the date of the first official meet at the Brooklands racing track near Weybridge, but the course will be open to the public for informal speed tests on June 15. At the present time the course is being treated with asphalt, and there is no reason whatever why it should not be quite ready for the date fixed. The course will be open every day for racing and private speed tests, and in addition there will be a number of interesting public competitions, the most important of which will be on July 16. A type of event which it is considered will be very popular is a race for cars of the same make and type. Thus there will be a race for 35-horsepower Daimlers, another for 30-horsepower White steamers, and another for 35-horsepower Mercedes. There will be special races for cars which have taken part in the important road races of the season, such as the French Grand Prix, the German Emperor's Cup, the Ardennes Circuit, etc. As an incentive to Continental manufacturers to send their machines over, the Brooklands committee will offer a prize of \$2,000 in connection with each of these races. Saturday, August 3, and Bank Holiday, August 5, will be important race days, while the event for the German Emperor's Cup racers will probably be on September 21. Handicaps and selling plates are being arranged for on much the same lines as in horse races. In fact, the general lines of conducting the Brooklands course will be those of the principal English horse-racing courses. A prize fund of \$75,000 has been set aside for the present season, a large proportion of which amount will be distributed on the opening day. The Brooklands track, built over the private property of Mr. Locke-King, is the first of its kind.

GENERAL VIEW OF BROOKLANDS AUTOMOBILE TRACK NEAR LONDON, SHOWING ONE OF THE BANKED CURVES FOR 100 MILE SPEEDS.

SOME FEATURES OF AUTOMOBILE CONSTRUCTION*

By THOS. J. FAY, E.E.

IN attempting to elaborate upon features of construction of automobiles, the dominant idea will be, to more or less discriminate as between (a) things tried out and found wanting; (b) things tried out and found satisfactory; (c) things in the air, so to speak.

It is believed, a society of engineers, to serve a useful end, should serve as a "clearing house" for engineering practices, rather with the expectation of ultimately fixing upon standards to go by. It is not the purpose here to advocate any scheme likely to limit the zone of activity of inventors, or place anyone in the position of having to conform to narrow conventions. On the other hand, it is feasible to aid invention and broaden the range of vision, by limiting the amount of details to be mastered, as well as decreasing the repetition of errors, costing as they do, *lives and money*.

It is not to be expected of any one to disclose advanced ideas of construction, yet, even so, a thing becomes free for discussion the very instant letters patent are granted, or the thing is placed on public view, and by discussion or the comparison of notes, the status of a device becomes, to a greater extent, a known quantity, when discussed by skilled engineers in a friendly way.

The speaker labors under the impression, borne of some experience, that it is to his advantage to have devices he may contemplate using or may have in actual use condemned for their faults rather than to be lauded for the advantages they may not possess at all, for in all truth an engineer, who follows up his errors, sticking to a narrow minded path of error, does damage to other engineers who may not be in a position to know of the fallacies; and to the public, who support an industry, the wrong is a double one, since the public may feel inclined to assume competence where incompetence may be the sole asset.

Engineers, then, may be frank with each other, for their mutual benefit and advantage, but they should be a little charitable in their criticisms, if for no other reason, because "glass houses cover a multitude."

Mistakes are only the products of activity, which, to illustrate, the speaker will cite an instance of a pattern maker he found in an establishment on an occasion, where the speaker assumed supervision.

The pattern maker in question was making a never-ending job of a bracket, of simple shape, and to hasten matters a little, the pattern maker was advised of the need of getting through some day.

Mr. Pattern Maker looked hurt, and by way of explanation he pointed out that he had never made a wrong pattern and he was at it for nearly thirty years; but the same pattern maker failed to explain that he had never finished a pattern, which was the true secret of his immunity from errors.

Engineers that do things do them right, if they know how, but they do them in any case, hence an engineer is a man that does right some times. If, then, engineers will confer a little, they will cease to be engineers at all, for as a result of comparison and discussion, they may succeed in always doing right.

Engineers are oftentimes placed in the position of having to do things that do not look right to them, simply because Mr. Commercial Man says "that is what we want." Mr. Commercial Man may not be amenable to argument, or may feel called upon to expose his dignity; but the consensus of opinion of a body of engineers would suffice to quell an earthquake, not alone to merely save the life of Mr. Commercial Man, who might otherwise allow his dignity to be exposed long enough to catch his death of cold.

Of the many points of construction in need of light and "more light," but few of them can be taken up at any one time, nor can any one man take time to become perfectly familiar with but a small part of the whole.

Since the last meeting of this society the speaker was afforded an opportunity to experiment at some length and more expense on the question of the means by which "alloy steel" may be machined and otherwise fashioned into shapes as required in motor cars, and if signs do not fail, the speaker labors under the impression he is not alone in the struggle.

It is one thing to say chrome nickel steel, for illustration, makes good metal for, say, axles, but it is another matter to say chrome nickel steel makes good axles. The best metal for axles is the best metal of which axles *can be made*, when it comes to facts, and chrome nickel steel does not grow soft in forging. To cope with this question, with a view to being able to say that commercially, important parts of motor cars could, as they should, be of nickel-chrome or other suitable alloy steel, the speaker has taken up the questions as follows:

- (a) The desired characteristics of the steel.
- (b) The desired shapes of the parts in which the steel may go.
- (c) The machine tools required in the process.

In the new "Ellsworth" car the results of these investigations will ultimately be found, and briefly the conclusions reached may be set down as follows:

Chrome nickel steel, for motor car parts of responsibility, in which parts must be forged before machining, the steel must be particularly low in phosphorus and sulphur, and the relation of carbon to both nickel and chromium must be closely regulated. Manganese must not be interjected to doctor the steel in the absence of carbon, and silicon must be held at a uniform low value.

Strange to relate, it does not matter who makes the steel, if it is of the requisite qualities; but all steel made will not suffice for the purpose; in other words, a nice appearing representative of a steel firm will not in anyway make unruly chrome nickel steel amenable to conditions adverse to its composition.

Moreover, this product seems to have widely varying characteristics for slightly varying components, and it is also suspected that even the chemical composition is not all to be taken into account.

In other words, the raw products, of which the steel may be composed, must, in some small measure at least, influence the workability of the steel.

As regards the desired chemical composition of chrome nickel steel it may be it can at first be discussed in the abstract, with a view to limiting the components, and thereafter fix the relations of the components to one another.

Taking this view of it, the question of phosphorus is of the first moment and might be settled as follows:

PHOSPHORUS RATINGS

0.010 to 0.012	}	The range of phosphorus in the finest product capable of being forged and heat-treated
0.012 to 0.015		
0.015 to 0.020	}	Low enough to be amenable to heat-treatment, forgeable, but lower in price than then the first named product
0.020 to 0.025		
0.025 to 0.030	}	Low enough in phosphorus to be used without forging or heat treatment, but too high to consider in the finest grades of cars.
0.030 to 0.035		
0.035 to 0.040	}	Limited to use in parts not likely to sustain severe shock loads, but not suitable for forgings.
0.040 to 0.045		
0.045 to 0.050	}	Very questionable product—probably not as good as ordinary nickel steel.
0.050 to 0.055		

*Paper read before the Society of Automobile Engineers.

The price of chrome nickel steel, while it is regulated by the "tariff," should be regulated by its phosphorus component first, and its sulphur component second, as follows:

SULPHUR RATINGS

0.010 to 0.015	} Very low value to be found in chrome nickel steel, of an especially forgeable quality.
0.015 to 0.028	
0.025 to 0.035	} Limits of sulphur in chrome nickel steel of a fine quality for forging, if the phosphorus is under 0.015.
0.035 to 0.045	
0.025 to 0.035	} Range of sulphur in inferior chrome nickel steel, showing phosphorus between 0.015 and 0.025 not suitable for forging or heat treatment.
0.035 to 0.045	
0.035 to 0.045	} Inferior product probably not equal in any way to good nickel steel, for less cost.

Manganese in chrome nickel steel should range about as follows:

MANGANESE RATINGS

0.35 to 0.45	} For steel holding about 30 points of carbon, 1½% chromium, and 3.30% of nickel.
0.45 to 0.65	
0.65 to 0.75	} For steel holding about 25 points of carbon, 1½% of chromium and 4½% of nickel.

Silicon seems to run about 0.20 per cent. for all the good grades of chrome nickel steel. It was found to be a little lower in some inferior product, and even a little higher in some good product; it would seem, then, as if the silicon rating should be fixed about as follows:

[SILICON] RATING

0.18 to 0.28	} For chrome nickel steel low in sulphur and phosphorus, with manganese about 0.40 and carbon about 0.30.
--------------------	---

The question of carbon is one not to be treated in the abstract at all, since carbon relates to nickel and chromium. Any procedure, then, involving the one must take into account the remaining two components. Having stated the abstract limitations, the best way to proceed, perhaps, will be to set down the formula of steel products and state results.

Chrome Nickel Steel—"A."

CHEMICAL COMPOSITION

<i>Chromium</i>	<i>Nickel</i>	<i>Carbon</i>	<i>Silicon</i>	<i>Sulphur</i>	<i>Phosphorus</i>	<i>Manganese</i>
1.40	3.30	0.28	0.20	0.015	0.012	0.40
to	to	to	to	to	to	to
1.50	3.40	0.33	0.25	0.020	0.015	0.45

Of copper and arsenic, a trace at most.

PHYSICAL PROPERTIES—NORMAL

<i>T. S.</i>	<i>E. L.</i>	<i>Ex-2"</i>	<i>Con. ½"</i>	<i>Structure</i>
120,000	100,000	24	67	
to	to	to	to	} Close

1	2	3	4	5
190	176	121	150	140

counting only the point at which both products bend until the test can no longer be continued.

After this test the chrome nickel steel may be bent double on itself, whereas the carbon steel would snap upon further bending, to any great extent.

This product is forgeable, and is rendered soft enough to machine by annealing to 630 degrees C. Forging should commence at between 1,000 degrees and 1,050 degrees C.—near the latter—and should be a continuous process down to 700 degrees C. to

about the formation of large crystals. Before forging the pieces should be raised slowly and through to 900 degrees C. and allowed to "soak" for a time. Prior to forging, each piece should be raised the remaining difference, and forthwith start the forging process.

The oil tempering process can be to 800 degrees C., with subsequent annealing to 550 degrees C., or to 1,000 degrees C. and subsequent annealing to 550 degrees C.

For gears to be oil hardened they can be raised to 1,000 degrees C., quenched in cold water, then in oil, and subsequently reheated to 335 degrees C. and cooled in the open. Gears thus treated will be both tough and hard.

Still another product, but somewhat higher in price, may be set down as follows:

Nickel Chrome Steel—"B."

CHEMICAL COMPOSITION

<i>Chromium</i>	<i>Nickel</i>	<i>Carbon</i>	<i>Silicon</i>	<i>Sulphur</i>	<i>Phosphorus</i>	<i>Manganese</i>
1.50	4.40	0.22	0.21	0.012	0.012	0.65

145,000	130,000	12	25	

The speaker has not tried this product "case-hardened," but he has seen case-hardened specimens and they looked to be thoroughly good in every way.

The especial value of this steel lies in its forgeability; it can be hammered out from a cube to a thin disc and show no signs of cracks, or it may be forged and expanded into weldless rings, one of which the speaker saw being two inches thick, with a bore or hole fully 18 inches in diameter. The normal physical properties are scarcely different from the physical properties of some very inferior product; yet even so, under the hammer or in heat treatment this product is vastly superior. To illustrate this point, an inferior product will be set down as follows:

Chrome Nickel Steel—"C."

CHEMICAL COMPOSITION

<i>Chromium</i>	<i>Nickel</i>	<i>Carbon</i>	<i>Silicon</i>	<i>Sulphur</i>	<i>Phosphorus</i>	<i>Manganese</i>
1.90	3.31	0.227	0.15	0.033	0.030	0.34

PHYSICAL PROPERTIES—NORMAL

<i>T. S.</i>	<i>E. L.</i>	<i>Ex-8"</i>	<i>Con.</i>	<i>Structure</i>
162,000	107,000	7.5	19	Open

This product is obviously not a fit product for use in any shape in a motor car; but upon forging, it exhibited almost no elongation in the expanding ring test; yet even so, the chemical composition would be considered good as ordinary steel is rated, and the high-sounding tensile strength would cause an increase in the respiration of a novice. There is a lot of this stuff to be had on the market, the price of which is high enough to give it the ring of quality; nevertheless, "beauty is as beauty does."

(To be continued.)

Some Common Defects.—We have recently pointed out certain forms of construction—notably in connection with the attachment of springs—which are as bad as they are common, and we therefore need not refer to them again, except to say that one may see even worse designs, which have been evolved by ignorance combined with the desire for originality, says *Engineering*. Another feature in which many makers show thoughtlessness is in the arrangement of the steering gear. In nearly half the cars the coupling rod is placed in front of the axle instead of behind, where it certainly should be.

CONCERNING THE USE OF THE DRY CELL

By ARTHUR F. JACKSON.

EVERY dry cell that will register between fifteen and twenty-five amperes on a reliable ammeter is capable of furnishing satisfactory ignition service, and if such is not obtained it is through no fault of the cell. No dry cell dies out without a cause—external conditions—which it does not control and for which it should not be blamed. An ignition battery of dry cells is as reliable as a safety valve to a steam boiler, and if users will be guided by its action they will be well on the road toward a solution of ignition trouble. Dry cells, when intelligently and properly used, furnish the best ignition. Superior to storage batteries, wet batteries, or magnetos, and the cheapest, cleanest and safest.

These are startling assertions, I appreciate, but nevertheless are demonstrable facts and I trust they will lead to a thorough investigation by competent persons, intelligent, with good "horse-sense" (not experts) and capable of putting aside prejudice. I have handled thousands of dry cells during the past two years, have made numerous severe tests along various lines, have been in close touch with manufacturers, have investigated a multitude of complaints, and have had the benefit of the experience of one of the most expert manufacturers in the business, who has devoted the past fifteen years to this specialty; so my statements are neither hasty nor immature. I have never had a complaint which, upon investigation, failed to show conclusively that the fault was not with the dry cell. During this time I have never had a cell or battery of cells which acted inconsistently, nor have I had one to depreciate quickly without external cause.

The reason for the unsatisfactory results generally obtained from ignition batteries of dry cells is *improper* use. There should be as much intelligence in the use of dry cells as given to the other details of the engine. It is generally the contrary. I will gladly contribute toward the necessary expense to carry on exhaustive *practical* tests of dry cells and of comparative tests with storage batteries and other sources of electricity for ignition if others will join.

Why the Dry Cell Gives Out Quickly.

An illustration of the conditions of use almost universally prevailing and the reason for poor service obtained from dry batteries is to be found in a complaint I attended to recently. John Smith, who is an intelligent young man, has a small repair shop for automobiles. He complained that he only obtained some fifty miles from a fresh battery of dry cells in his own car. Investigation showed that he had a high-grade coil, which he recently paid \$80 for. Tested current consumption of coil. Found one unit taking in excess of four amperes rate of current and the other three units taking between two and four amperes. Also, one vibrator frequently *stuck* to the point and caused a dead short circuit. Impossible to adjust coils to proper rate of current. This condition is absolutely improper and unnecessary, for good coils—and this make is of highest grade—only require from 1-4 to 3-4 ampere rate of current for perfect ignition. This coil had been injured and possibly ruined by abuse without anyone being the wiser.

Another point which is not understood is the matter of voltage and amperage. Many are under the impression that excess of voltage is injurious to coils, but that any ampere rate of current may be used without harm. This is exactly contrary to facts. A few volts more than absolutely necessary will not injure the most sensitive coil, but an excessive rate of current—regardless of its pressure or voltage—will cause arcs at the vibrator points, quickly causing a pitting of the platinum points and the points of the plug and create other harmful conditions in the various parts of the ignition system. And this excess current is gen-

erally caused by insufficient voltage at the primary terminals.

Dry cells have a peculiar ability to offset inadequate voltage by increased current, although it quickly exhausts them. Many users are under the impression that because a dry cell registers 1 1-2 volts by meter test when fresh and unused they should use four-cell batteries for six-volt coils. This meter measurement is the inactive pressure. It is the initial voltage and a false voltage. The voltage or pressure of the service current of dry cells is between one volt and 1 1-4 volts, consequently not less than five-cell batteries and preferably six-cell batteries should be used with six-volt coils. A six-volt coil will have to be adjusted to a high rate of current when fed with a four-cell battery. The same coil will furnish perfect service with a current of 1-4 ampere when fed with a six-cell battery and not require further adjustment—it will not arc at vibrator points and will not suffer an internal short circuit. In fact, will be under proper conditions, and the ignition will be fast, hot and satisfactory.

Another condition which prevails is the misrating of coils. There are some jump-spark coils on the market and largely sold—represented as "six-volt" coils—which require 10-volt to 12-volt batteries to properly feed them. It results in users connecting them with insufficient batteries and obtaining not only poor service, but very short service from each battery. The fact that a coil may be "sparked" with a certain number of cells of battery is not an indication that that is the proper size of battery to use. You may "spark" a primary coil with a single cell, but the amount of service which a cell would furnish might be but a few minutes. It is the same with jump spark coils. A battery of three or four cells will spark them, but that does not indicate the proper size battery to use. The proper size battery is that one which experiments show to furnish the maximum amount of service and best quality of service with minimum deterioration.

Other Parts of System Also to Blame.

The timers, too, are responsible for a large amount of ignition trouble. It is a mistake and a misunderstanding of their true purpose for manufacturers to disregard battery consumption when designing this apparatus. A timer which is built with the sole purpose of long continued term of spark service ignores another condition, just as important, which it should control—battery service. Such a timer provides but a trifling interruption of the current, and at the high speed of automobile engines the current is so nearly continuous as to amount to closed-circuit conditions and cannot be met by dry cells. This disregard of current interruption is entirely unnecessary, for there are many timers which are perfectly satisfactory in service and which have such an interval between points of contact as to make a definite interruption of the current.

The matter of the grounding of the battery should have more intelligent treatment. It is not sufficient to ground on any metal part of the frame or engine. The further from the point of action and the more indirect the course, the greater the current waste and the slower action will be obtained. The primary current is very feeble and it is ridiculous to make it search for a way and overcome such obstacles as rust and metals of different conductivity to reach the point of action. Ground your primary wire close to the plugs or where the conducting medium is direct and of high conductivity.

Keep batteries absolutely dry. Protect them from any metals coming in contact with them. Avoid frequent ammeter testing. Make the interbattery connections only with such connectors as *cannot* extend beyond the rim of the knurled nut. If batteries are quickly exhausted or run down between periods of use search for the trouble in your ignition system and correct it. Dry cell batteries do not do this without cause.

MINOR PROBLEMS OF THE AUTO CAB

By W. F. BRADLEY.

WITH the advent of the automobile cab and the automobile omnibus new problems present themselves. Although a more costly and a more important unit, the ponderous 40-horsepower, 50-passenger omnibus such as is in use in large European cities, is an easier machine to construct and a simpler one to keep in operation than the modest 10-horsepower cab, which has become a necessity to Parisians and Londoners and will soon take out its naturalization papers in New York and other American cities. While 'buses are being constructed in hundreds, cabs are being turned out in thousands. Greater care can—indeed must—be selected in the choice of drivers for the heavy brigade, and their fixed itinerary allows them to receive attention from skilled mechanics in a manner altogether impossible with the small freelances.

At least half a dozen European constructors have designed and produced special cab chassis which may be described for want of a better word as absolutely fool-proof. Given two pupils equally ignorant of driving and caring for an automobile and a hippomobile, and the one with the modern auto cab would certainly become a safer individual to turn loose on the crowded streets of a big city than the latter in a given space of time.

But the auto cab driver is no more self-evolved than is any other type of genius. He has to be made by outside agencies, and the outside agencies for his making are not to hand. Paris has discovered this to be true. The first three hundred cabs to be put in operation were commanded by a superior set of men, young men who had the foresight to discover a future in the automobile cab, who studied the automobile or left positions in the mechanics' shop for a freer life in the open air. They were competitors and as such had to be efficient to succeed. But Paris has a fleet of 10,000 cabs in constant service and it is not to be expected, nor is it desirable, that when these are cast aside, as they will be within two or three years, that the veteran horse drivers should be abandoned also. Training them, however, to handle even a simplified Renault, Darracq or Bayard-Clément, automatic in almost everything but changing of gears, braking and steering, is an elaborate procedure. A score of stories could be told of the stupidity and gross ignorance of the horse cab driver who has abandoned the reins and the whip to sit behind a steering wheel. Some of them would be comical if they were not utterly stupid. A well-known automobilist relates how one evening he jumped into a Renault cab and told the driver to take him as quickly as possible to a street high up on the Montmartre hill. In the Rue Lepic, with its 10 per cent. grade that the horse drivers refuse to negotiate with a load, the little Renault stopped dead and began to run backwards until the driver had the sense to apply his brakes.

Turned round to his passenger, the undergraduate-chauffeur said: "Can't get up there; it's too steep."

In an instant the passenger was out, cast a rapid look over the machine and said: "Why, you are driving on second; if you can't get up on second, use your first."

"Oh, they told me to put the lever in that notch there, that's all I know about it," said the ex-horseman.

"Let me try; you see I have my license; it is for the same make of machine, and as I have often climbed this hill with a heavy closed car, I don't see why this light machine should not do it."

In a second the engine was cranked, the machine started easily on first speed and reached the top on second gear. The journey over, the passenger thought a little gratuitous instruction would not be amiss. Raising the hood, he said: "How many cylinders has your motor?"

"I don't know," was the reply.

"Well, there are two; see, one, two," touching them.

"Oh, yes, there are two," said the driver, complacently. Had he been told that there were six, he probably would have assented just as readily.

Government regulations require that every driver of an automobile shall have a thorough knowledge of the mechanism of his machine. Sometimes the inspector is conscientious and, after assuring himself that the candidate can steer round a block without shaving the mud off the market wagons, will order the hood to be removed and will pose a few questions. The proprietor of an automobile school whose pupil was refused owing to inability to lay his hand on the carbureter without hesitation, was indignant against the authorities and asked with rising wrath, "How much do they expect us to teach them for ten dollars?"

It has been suggested that a special operating license should be granted for automobile cab drivers, comprising merely an ability to steer a car, and supposing no mechanical knowledge. Such a plan would doubtless be prolific of incidents similar to the one which recently came to our notice, when a driver telephoned to headquarters that his machine was broken down, lodged himself comfortably inside the cab and waited an hour until an expert arrived on an emergency repair van to replace a detached wire.

There is no alternative for operating companies. Although it may call for the expenditure of a large sum of money, they must be prepared to train the existing raw material as promoters of other new enterprises have had to do. When the gasoline cab comes to this country it will go through the same ordeal as the Paris vehicles are now enduring. The initial vehicles will be handled by men already versed in automobilism, the mass of them will have to be turned over to men only familiar with four-legged power. On the pains taken to convert this raw material will depend, to a certain extent, the success or otherwise of the poor man's automobile.

AUTOMOBILE TRAINS FOR BARBIZON.

PARIS, May 13.—Every visitor to France has made a pilgrimage to Barbizon, rendered immortal as the home of Millet and the hallowed ground on which was painted *L'Angélus*. Had not the famous painter discovered the village it never would have been known except as one of the many picturesque and peaceful retreats on the edge of the Forest of Fontainebleau. The wincey diminutive locomotive which for a number of years has united the village with Melun, the nearest town, and carried thousands of pilgrims from all lands to the historic shrine, will no longer share the road with automobiles, cyclists and market carts. It has been replaced by a more modern means of transport in the shape of a Decauville automobile on rails. The motive power of the train is a 16-horsepower, four-cylinder Decauville gasoline engine mounted on an open car similar in general appearance to the summer surface cars of New York. A load of thirty passengers can be carried at a speed of twenty miles an hour on the level, and the engine is sufficiently powerful to climb the 10 per cent. grades met with on the road. Not only will there be a considerable saving in time, but a more economical service will be obtained by the conversion to gasoline.

A repair wagon driven by a four-cylinder gasoline engine has been adopted for use on the Paris Metropolitan underground railroad. The gasoline motor has been proved after experiments to give the best results for this class of work. The wagon is intended for use only when the electric current has been cut off in order that the breakdown gangs may work on the track with greater security. In addition it will be used as an inspection car during the hours when the ordinary service is suspended, electric trains not running between one and five in the morning.

DEVICES FOR BEATING THE FUEL RULES

NOT only the Grand Prix, but other smaller French races are to be run this year on a limited fuel allowance. To preclude the possibility of fraud the club committee stipulates that filter, stopcocks, carbureter intake and tank fillers must be sealed according to their instructions; an illustration of these methods was shown in the issue of THE AUTOMOBILE for March 28. If the driver can cheat the regulations and give to his engine more gasoline than the committee placed in the tank, his horsepower can be increased and his chances of winning thereby enhanced.

FIG. 1.—First prize winner, device for adding gasoline to gravity feed tank.

We reproduce the three winning systems, and give a résumé of the manner in which their designers intend them to be used. First prize winner says that although the method of sealing the fuel apparatus is not perfect, it is advisable to leave the seals severely alone and get an extra supply of gasoline, as shown in the sketch. There is no stipulation as to the position of the fuel tank; thus he would place it under the seat. The driver would carry concealed under his clothes, and held in position by braces, an india-rubber bag containing four or five gallons of gasoline, a rubber tube with a stopcock being attached to the bag.

One of the rivets in the top of the tank is specially prepared to lift out or to hinge open, leaving a hole in the tank through which the rubber tube can be passed. Between the top of the tank *L* and the frame *O* is a certain space filled with cotton waste or tools. During the race the driver stops, fumbles about under the seat as if to find a tool, but in reality pushes the end of the tube through the hole into the tank. By leaning against the back of the seat pressure can be exerted on the tank and the gasoline forced out.

Fig. 2 supposes that the tank is under pressure. Generally in such a case the oil is under pressure also, contained in a cylindrical tank within the chassis. In nearly every case the tank is supplied with a cock to relieve the pressure when it is desired to fill. In order to cheat the regulations this tap, instead of

FIG. 2.—Second prize, device for adding gasoline to tank under pressure.

communicating simply with the interior of the tank, is connected with the air inlet. As this pipe is branched on to the air pipe leading to the gasoline tank, nothing is more simple than to send a supply of gasoline where it is needed. The manner in which it is carried is practically the same as that described for No. 1, and will be readily understood by reference to sketch.

Fig. 3 prefers to operate with a tank under pressure. Generally this arrangement comprises an air pump, and it is this which furnishes all that is necessary to cheat the regulations. If this pump can be made to pump gasoline instead of air, it is evident that it will fill the official tank without anyone being aware of its villainous rôle. The accompanying sketch shows how this is done, and it is hardly necessary to enter into details. A rubber tube connects the pump with the illegal tank, which in this case would be a tire carried at the rear of the car. During the race the machine would stop at the tire station, take on board a batch of tires, one of which would contain gasoline instead of air. While the car is running the mechanic would make the connection and on quiet stretches of the road would send a quantity of gasoline through to the official tank. If the pump were fitted with a spring the mechanic could operate it with his foot with still less fear of detection. By this arrangement the driver could take a fresh supply of gasoline at each round if he desired and thus beat all fuel consumption records.

Probably the chief value of the "frauding competition" will be that it will render fraud even more difficult, for, having had revealed to them one hundred methods by which their regulations might be brought to naught, the committee will be on the watch to see that none of them are put into practice. In the Grand Prix, run on a guarded course under the eyes of thousands of spectators and carefully watched by numerous officials, even the most ingenious of the frauding practices would be put into operation with great difficulty. In touring competitions they might be successful.

FIG. 3.—Third prize, arrangement for using pressure pump to obtain additional supply of fuel.

POPULAR FETES TO PRECEDE GRAND PRIX.]

PARIS, May 16.—As a prelude to the Grand Prix, to be run on the Dieppe course on Monday, July 2, there will be a series of motor boat races off the town of Dieppe on the Sunday of June 1. A triangular course, about three miles round, will be marked off, sufficiently near the shore for the races to be followed constantly by spectators, and the start will be arranged so that the contest will finish about 3:30 in the afternoon on account of the tide. Details of the boat races have not yet been discussed, but owing to the location of the town, three hours by rail from Paris and five hours from London, a huge attendance is counted on. During July and August Dieppe is the seaside resort most visited by holiday makers, English people being almost as numerous as the native French, for although the Britain is no lover of the Continental Sabbath on his own shores, he is particularly happy to have the opportunity of running across the Channel for a week-end relaxation. A prize list of \$4,000 is already assured. The fastest French, Italian and British boats will compete.

REMEDIES FOR ROADSIDE PERPLEXITIES

By THE MAN AT THE WHEEL.

NOT long ago I came across one of those owner-drivers whose skill at the wheel is second to none, but whose knowledge of things automobile does not extend a great way beyond this essential. He is one of that numerous class that looks upon the magneto with reverence akin to awe; it's all right as long as it continues to perform its duty, but when it goes wrong he's all at sea and simply doesn't know where to begin to open it up to get at the *works* when anything goes amiss. This was the case when I saw him last, for his car was at the side of the road, and he had a puzzled air of helplessness that would have appealed to a rapacious constable. His very expression seemed to say "Won't somebody kindly help me out of this?"

He explained things in a few words; his car was fitted with a duplicate system of ignition throughout, but the accumulators, being in need of recharging, had been left behind in the garage on charge, particularly as he was only out for an afternoon's run and had not intended to go very far. And he had not got as far as he had intended before the motor began to miss and finally stopped. Naturally he blamed the magneto, and sure enough the magneto was at fault. It had run all last season—in fact, ever since the car had been put in commission, and during that time a great many miles had been covered without so much as a look at the machine. It was a well-known make of the high-tension type, and he felt considerably relieved to see me remove the shield that covers the contact maker. A little oil and a little dirt in the wrong place, but chiefly a contact spring that had lost much of its youthful powers was the sole difficulty, and it did not take five minutes tinkering altogether to put things right again.

Increasing Fuel Consumption with Age.

Why should a motor use more gasoline as it grows older? is a question that crops up every now and again, and one that I heard brought to the fore by an autoist quite recently. "I always managed to average a good 18 to 20 miles a gallon on give-and-take roads around this district, and that means more or less hill-climbing all the time, but now I don't seem to be getting much more than 15 or 16, and sometimes not as good as that," he said, in explaining matters. Granted that, other things being equal, a motor runs easier once it finds itself, as the saying goes, why should it not continue to run just as easily and develop as much power as when it was new, so long as it is kept in good running order. In fact, there have been stories to the effect that, like a man attaining his prime, a motor developed 20 to 25 per cent. more power when it was five or six years old than when it was brand new. The accuracy of such stories naturally depends largely upon the imagination of those who tell them, and when sifted carefully it is found that, as a general rule, the driver who tells them depends very much upon his instinct as to "how she pulls" regarding the amount of power developed.

But where an autoist is sufficiently observant to make careful record of the car's gasoline consumption, and detects a falling off in performance of a mile or two to the gallon, the matter is different. It goes without saying that any piece of mechanism loses in efficiency with age, despite the best of care, but there are not many automobiles in daily use that are old enough to come in such a category as would be implied by this. The motor in question had done some 10,000 to 12,000 miles, extending over a period of two years, with an almost unvarying record of fuel consumption. The case might appear puzzling at first sight, but a little questioning shed considerable light on the matter, and investigation proved the diagnosis to be quite correct.

The car had not been used much during the winter and had been put in commission without any preliminary overhauling of any kind. It had run probably a month or more in this condition, during which time the fault complained of was noticeable.

Gummed oil and carbon under the piston rings, preventing proper seating, and valves that needed a bit of regrinding, seemed to be most likely causes. Instead of resorting to the makeshift of flushing out with kerosene or gasoline, the delayed overhauling was given and the motor dismantled. The rings were found to be chiefly at fault, as the accumulation of caked oil and soot had prevented them from bottoming in their grooves at all.

An Unsuspected Cause of Ignition Trouble.

There is little doubt but that in the average autoist's mind the ignition ranks highest as a disturber of the driver's peace of mind. And his estimation of it is well founded at that, for it has been figured that, taking automobile shortcomings as a whole, the petty defections of the ignition system constitute fully half, and are in consequence accountable for most of the delays. But, though the ignition itself may appear to be at fault, it is not always due to some inherent cause, for, besides being the root of a very large part of the troubles that cause halts by the wayside, it also is the most susceptible essential of the power-plant. I saw this strikingly exemplified only very recently. Going along an out-of-the-way back road in the country road, I came across a party camped by the wayside. There were two young fellows and two girls, and the former looked as if nothing short of a Turkish bath would ever make them feel comfortable again, so dirty and bedraggled did they look; the feminine end of the party was still immaculate in all its summer finery, and though they had made light of the mishap at first, by the time we came along they looked as hopeless as the other two, for we were the first thing to pass along that way in two or three hours.

The car was of the light touring type with a horizontal-opposed engine under the body, so it may appear at first sight as if the predicament in question mainly grew out of its peculiarity of construction, but there is a lesson to be learned from it, none the less. Our proffered assistance was only too eagerly accepted; if we had gone by without at least the offer of a tow they would indeed have felt in the position of the shipwrecked party that sees its last chance of rescue fade below the horizon. "What's the trouble?" only brought a sadly prolonged negative shake of the head. A tow was the only thing in the driver's opinion, and though his knowledge of things automobile had suffered a severe tumble in the estimation of the rest of his party during the past few hours, no one suggested anything.

We began to nose around, and, as a preliminary, took out the spark plugs, much to the disgust of our friends, who remarked that they had had them out a dozen times or more, and they worked all right. The motor would start without any great difficulty, but would lay down again often before it had gone a block. A look at the plug ends showed quickly enough what was the matter; they were dripping with fresh lubricating oil, the gap of one of them being bridged by a fine big globule of the lubricant. There was no sight feed on the oiler, properly speaking, only a "bleeder," so-called, because it could only be called upon to see whether the oiler was working or not. We opened the oil tank and it was empty, though we were assured that a quart of fresh oil had been dumped into it before starting out. The rest hardly calls for any explanation. On opening the crank case it was found that the oil in it was so deep that it was slopping around inside the pistons. It was only a matter of a few minutes to draw most of it off, adjust the oiler properly, and fill it again. This and a cleaning of the plug ends set things right, and we were profusely thanked. While the ignition of an engine of this type is more prone to be interfered with in this way, an excess of oil is equally bad in a vertical engine, and it will work above the pistons. Beside its tendency to burn and form a troublesome carbon deposit there, it will also find its way to the spark-plug terminals and cause the cylinders to miss.

LETTERS INTERESTING AND INSTRUCTIVE

The Popular Fallacy of Starting "On Compression."

Editor THE AUTOMOBILE:

[751.]—In your issue of April 25, 1907, under heading "Brief Items of News," you have an article in which it is stated that a certain make of car, which was at the time in St. Louis, was started from the seat by the spark, after standing for one week; claiming that the compression had been held for that length of time (?).

I have frequently started a four-cylinder car by opening petcocks over cylinders, and squirting in a little gasoline, closed petcocks and started car from seat, without cranking, by throwing switch plug. There was no compression in cylinders.

Will you please explain these matters?

It does not appear to me to be necessary for an engine to have compression in cylinders to start from spark (or seat), if the gasoline vapor is there in sufficient quantity to ignite.

Dallas, Tex.

F. S. T.

Much of the ground included in your inquiry is covered by the answer in this issue to the letter of A. Conrad. As there noted, the popular impression that the sole reason for the ability of a motor to start by switching on the current lies in its capacity to retain a compressed charge indefinitely, is very general. It is merely one of those popular fallacies that originate in the air and take such firm root that it is impossible to eradicate them. Your experience in starting a motor from the seat merely by priming with gasoline through the petcock is a common one and can be repeated almost indefinitely on any good motor. Should such a demonstration fail to convince some of the doubting Thomases that the motor did really start without any preliminary compression of the charge, a very simple experiment should be sufficient to remove all question. Take an old tin can, spray its walls with a little gasoline; give the latter time to evaporate and then invert the can over a spark plug. Switch on the current and, unless too much gasoline has been used, the way the can will jump at the resulting explosion will be eye-opening. A modification of the experiment may be made by taking a short piece of iron pipe and plugging it at both ends with corks, through one of which the connections for firing the charge are inserted.

Tire-Valve Information Inquired For.

Editor THE AUTOMOBILE:

[752.]—Though I consider myself a seasoned motorist—if five years' experience as an owner of cars deserves to be termed a seasoning process—there are a whole lot of things that I desire to know about tire valves. Simple as this very small detail of automobile construction seems to most people, I believe that it is less understood than many a detail of far greater importance and complication. At least, in my own experience I am free to admit having never solved a number of the tire valve problems, and I am equally free to admit a thirst for information. Can you not, in "Letters Interesting and Instructive," explain a few of the peculiarities of tire valves—the ones with which every automobile user at one time or another has been confronted? For instance, what are the purposes served by each small part of the standard type of valve; what is the reason for valves sticking as they do sometimes against the pump, etc.?

DR. ELTON CARTER.

Madison, Wis.

The ordinary Schrader tire valve, now applied to nearly all automobile tires, is a much simpler affair than your criticisms suggest, but it is, as you say, subject to at least a few rather disconcerting ailments. Almost any tire catalogue shows sectional and other views of valve constructions, however, so we do not feel justified in using space to answer this portion of your inquiry. The sticking of valves, in spite of the highest pressures that can be brought against them by a pump, is due wholly to their exceedingly small size. The usual condition in a case of this kind is that the tiny rubber washer used to insure airtightness becomes gummed to its seat, in which condition it exposes a circle probably not over one-sixteenth of an inch in diameter to the pressure. The consequence is that a pressure even as high as one hundred pounds to the square inch figures out only about five ounces on the area it can reach, and this force is quite likely to be insufficient to dislodge the adhering part.

Position for Carbureter on Two-Cylinder Motor.

Editor THE AUTOMOBILE:

[753.]—Will you kindly give me some information on the following points? I have a two-cylinder, double-opposed, horizontal motor, the carbureter and intake manifold of which are situated, as per the accompanying rough sketch. Can I alter this so as to feed the fuel nearer to the inlet valve of one cylinder than the

DIAGRAM ILLUSTRATING LOCATION OF CARBURETER AND MANIFOLD

other, and obtain as good result as is at present the case where the fuel is fed from the center of the intake manifold? By being able to feed the fuel from one end, I can save two elbows in the piping and reduce the length by about a foot of pipe, which should make the fuel better.

W. M. CASE.

Clarksville, Tenn.

Erratic running is apt to result from such a change as you mention, owing to the fact that as thus arranged one cylinder will be exerting a much more powerful suction on the jet than the other and the ratio of gasoline and air will accordingly vary with each power stroke. If it is merely desired to remove the carbureter to one end of the motor from its present position, this may be done by leaving the main portion of the manifold as it is and extending a horizontal branch from its center to the new location of the carbureter, as is done in the case of motors having such an arrangement. Designers differ as to the importance of having the carbureter as close to the inlet valves as possible and, while numerous motors are built on this plan, others are designed with the carbureter on the side of the motor opposite the intake, thus entailing an extra 20 to 24 inches of pipe or more. The theory is that the mixture is apt to wire-draw or condense in its passage through a long tube, while the opposing opinion of those who favor the long tube is that it always holds a supply of the mixture in reserve and its constant movement through the tube tends to make it more homogeneous, while the proximity of the tube to the cylinders prevents condensation. Thus the saving of a foot of pipe would hardly constitute a material benefit; the elimination of two elbows, particularly if of the right-angled type, might be of more importance, but as you have shown the manifold in your sketch it has uniform curve with an easy entrance at the valves, and we fail to see how you can improve upon this merely by shifting the position of the carbureter. If you will look through the back numbers of THE AUTOMOBILE you will find a case where a subscriber complained of having a great deal of trouble from just such an arrangement as you consider installing, and we advised him to alter the manifold so as to make the carbureter equidistant from both cylinders.

Recharging Dry Cells and Accumulators.

Editor THE AUTOMOBILE:

[754.]—Can a dry battery be recharged, and if so, how? I have at my disposal a dynamo and small switchboard, and from these how can I recharge a storage cell?

H. RELHAM.

Chicago, Ill.

It is possible, but not commercially practical, to recharge a dry cell. The latter does not constitute what is technically termed a reversible voltaic couple, *i.e.*, one in which the chemical processes of formation occasioned by the passage of an electric current through it, can be reversed by connecting the cell to some other piece of apparatus and using the current drawn from it. If a battery of dry cells be placed on charge for a considerable length

of time, a slight current may be drawn from them, but it would be about equivalent to pouring a bucket of water on a large quantity of sand and then squeezing the sand in an attempt to recover the water.

To charge a set of accumulators, the latter should be connected up so that the charging current is sent through them in the proper direction; that is, the positive pole of the dynamo must be connected to the positive terminal of the battery and the same with the negative. You do not mention whether your dynamo delivers an alternating or direct current. If the former, it cannot be used without the use of a converter of one type or another to alter the character of the current. We presume it is of the direct current type, so that this is not necessary. By storage cell we presume you refer to the ignition sets of accumulators usually employed, and will take one of these as an instance. Assuming that it is a six-volt set with a capacity of 60 ampere hours, the current sent through it must be regulated to conform to its size. The safe discharge rate of an accumulator is also its safe charging rate as a rule, and the former is generally stamped on the cell. In the case of a set such as mentioned the safe maximum would be a current of 10 to 15 amperes, thus completing the charge in from four to six hours. This is not at all to be recommended, however, as the slower the charge the better and a current of 2 to 4 amperes, extending the charge over a period of 15 to 30 hours, would be much better. The rheostat or resistance mounted on the switchboard should be employed to reduce the current to the amount required. You do not mention the voltage of the dynamo you have, but unless the latter be of the type employed for electro-plating, which is designed to give a large amount of current at a very low potential, it can be used. The current should have a potential of about 9 or 10 volts at least, as the cells when approaching the end of their charge reach a voltage slightly in excess of 2.5, or close to 8 volts, for the three-cell set. The evolution of gas becomes quite violent as the cell approaches repletion and the solution appears to be boiling, this often being regarded as an indication that the operation is complete, but it is not always reliable. Testing each cell with a low-reading voltmeter or with a hydrometer should be resorted to; in the former case the reading should be 2.5 volts or over, and in the latter a specific gravity of 1.2 to 1.26.

What Is the Cause of Lost Compression Here?

Editor THE AUTOMOBILE:

[755.]—I am a very interested reader of your "Letters Interesting and Instructive." Would like you to give me some information on the following:

I have four-cylinder motor, the dimensions of which are 4 1-2x5 inches; have run about 2,500 miles; when I first got the machine I could start on compression, and this was true until some time ago. Now it is impossible to start motor that way; in fact, after standing for some little time have to prime the cylinders before I can start. Have adjusted the carbureter in every possible way, reducing the air and gasoline and increasing both, but all to no effect. The motor has good compression, and once under way runs excellently; answers quickly to the throttle and to the slightest advance of the spark lever, but when throttled down will miss explosions and occasionally stop. Can make about 16 miles on a gallon of gasoline, which is considered very good in such a hilly district as this. Can you help me out? A. CONRAD.

McKeesport, Pa.

In diagnosing the trouble you have experienced as set forth in your letter, it is necessary to treat of it as two separate and independent ailments, as it does not appear that the failure to start on compression has any connection with the fact that the motor will not run satisfactorily at slow speeds. And before taking up the first, it may be as well to explain that there is considerable misapprehension extant as to the requirements of starting on compression, as it is called. It is generally conceded that it is practically impossible to make joints sufficiently tight to hold a gas under high pressure for any considerable length of time and it is doubtful if there is an automobile motor on the market that will retain more than a fraction of its initial compression for more than 24 hours. This does not mean that the motor cannot be started from the seat after that time, as there are cases on

record where a motor has been started in this manner after standing unused for a week or more, one such case being cited in these columns in the present issue (letter of F. S. T.), but it shows that the motor does not start *on compression*, contrary to the popular view. It does mean, however, that the cylinder about to fire has retained sufficient explosive mixture to ignite when the spark occurs, and as a mixture of gasoline vapor and air when exploded in a closed vessel without previous compression, generates a pressure that has been known to reach as high as 90 pounds per square inch, it will readily be evident that this is sufficient to start any well-balanced motor in good running order. One of two causes may be responsible for your present inability to start the motor by switching on the current without previously priming the cylinders. Either the valves and piston rings of the motor may have worn sufficiently to permit the escape of most of the gas or the surrounding temperature may have caused the condensation of the gas in the cylinder, this usually being the case in winter. The wear mentioned might be sufficient to permit the gas to leak away when thus standing and still not impair the compression of the motor sufficiently to make a perceptible difference in its working, owing to the fact that the film of lubricating oil that is formed is essential to good compression, and this film disappears when the motor stands idle for any length of time.

Carbureter trouble would appear to be the most likely cause of the second ailment, and the missing at slow speeds seems to indicate a mixture too rich in gasoline. It must be borne in mind, however, that the modern automobile motor is not designed to run at very slow speeds, and should not be expected to function regularly under 200 to 300 r. p. m.

A Question of Axle Design.

Editor THE AUTOMOBILE:

[756.]—Why is it that the front axles of automobiles are made heaviest and strongest at their ends, while rear axles are made stronger at their centers? I should think that the center would be the place for the strength in both axles, on account of the greatest strain being there. In all other structures, such as bridges, beams, and even the side members of automobile frames, the strength is placed at the middle; why not the same with a front axle? AMZIE GIFFORD.

Davenport, Ia.

Like many another criticism of standard automobile construction, yours comes from a misconception of conditions. An automobile front axle would need its greatest strength in the middle, as you suggest, if it were loaded at the middle and supported at the ends, as in the cases of the bridges, beams and frame members you cite. But, as a matter of fact, automobile front axles are supported at the ends and loaded—through the medium of the springs—at almost the same point. So the bending stresses due to load and road shock are not only much smaller than might appear, but are concentrated on the thickened ends of the axles. Were an axle loaded at the middle, the condition would be different, and then it would be sound engineering to use a beam construction with greatest strength in the middle. This has been the case with some old cars, and is the case now with the rear axles of propeller shaft-driven cars, which are loaded not alone with the vehicle, but also with the bevel gear drive and the differential.

Reaching Port with a Broken Chain.

Editor THE AUTOMOBILE:

[757.]—I have a car propelled with a double chain drive, and while on a short run a few days ago one of the chains pulled apart in such a manner that I was unable to fix it with any facilities afforded by the tool box. The result was that I finally had to have the car towed in, it proving impossible to drive it with one chain because the propelling effort was all absorbed in rotating the differential. I have since heard, though, that there is some way of tying parts of the mechanism so that the car can be run despite the missing chain. Will you please tell me if this is true, and, if so, how it can be done? E. A. KLING.

Sedalla, Mo.

By tying the countershaft sprocket over which the broken chain ran, so that the half of the countershaft to which it is attached cannot revolve, it is perfectly prac-

ticable to limp in on one chain with a car of the type you possess. To do so, however, especially if the distance be great, is to impose very heavy work on the differential, which is revolved under these conditions under heavier and more constant duty than any for which it is designed. A good precaution, to minimize possible trouble from this source, is to clean and lubricate the differential thoroughly before attempting the run. And it goes almost without saying that no high speed should be attempted. By all means the best plan is to secure a new chain, which will have the additional merit of impressing the desirability of carrying a spare one in the future.

A Propeller Shaft Breakdown.

Editor THE AUTOMOBILE:

[758.]—I am a driver of a small car possessed of propeller-shaft transmission to the rear axle. Several days ago I had the car out for a seventy-five-mile run, which I made in four and one-half hours over hilly country, but when within two miles of home I found myself in serious trouble. The car had been stopped for a few moments—up to which time it had seemed to run all right—and when I started up again for some reason the low gear refused to engage properly. I forced it, and the result was a lurch forward, followed by a grinding noise which continued as long as the engine ran, though the car stood still. I thought, of course, that the bevel gears had stripped, but an examination of them through a small opening in the case failed to disclose anything wrong. Nor does the change-speed gear seem injured. I now want to know what the matter is before I proceed further, for I fear that otherwise I may add to the trouble.

J. K. FOOTE.

Middletown, N. Y.

Several important points that might help the diagnosis are missing from your enumeration of conditions. You fail to state whether the change-speed gear is of the planetary or sliding type, and you do not assure us that the propeller shaft is all right. If the propeller shaft is of the type that is enclosed throughout its length by a non-rotating housing, it seems altogether likely that the shaft itself is broken, probably with a more-or-less irregular fracture, so that the ends scrape together. Or perhaps the propeller shaft is broken out of the bevel pinion, or away from the shaft that drives it, by the shearing of some key. Mere inspection of the bevel drive through a small opening in the case does not seem to us sufficient assurance that the bevel pinion is not stripped, and we would suggest disassembling the car until the trouble is definitely found. No more damage than already exists can result from this, if it is done carefully. As near as we can judge, the accident seems to have occurred through too sudden engagement of the driving mechanism, perhaps on an up-grade or in heavy pulling. This could be caused either by too quick throwing in of the clutch or a "fierce" condition of the clutch surfaces, possibly due to a coating of dust accumulated during the long day's run.

MR. MILTOUN SAYS FRANCE GREETES TOURISTS.

Editor THE AUTOMOBILE:

[759.]—The writer would like to reply to the statement made by your unknown correspondent, No. 701—an American automobilist, living at Vernon Eure—that invading American automobilists will not be chivalrously received in France.

The French as a nation, so far as they are in touch with touring automobilists, hotel keepers, mécaniciens and the like, may be depended upon to do nothing to drive trade away—and it is a very considerable "trade" that the visiting automobilist does in France, by spending his money liberally in hotels and garages. There may be exceptions to this ideal class of tradesmen, doubtless there are, but the writer has not found more than a half dozen lonely examples in a round of French touring of many years, beginning with a DeDion tricycle and so on through the gamut of automobile things until he has arrived to a "real" touring car.

As for the menacing gendarmes, they only do their duty when they ask you for your "papiers," if by chance you have come to rest at some picturesque spot just as a brace of them stroll by. All automobilists look alike, begoggled and berugged, and they don't care a jot whether you are a Frenchman or a stranger so long as they can make a report to their brigadier that they caught up an automobilist this morning. "sans papiers" or whose "papiers" were not "en règle." Whose fault is that, not the gendarmes', surely!

Now for speed limit, when you come to a great, staring sign indicating that speed in a narrow-built, twisting Grande Rue of

some hitherto unheard of little French town is, "by order of the Maire," reduced to ten kilometers an hour, it's wise to follow the warning—for many reasons.

The writer was recently an occupant of a high-powered car which bowled over a great shaggy "chien de berger" in a small town in Vaucuse recently, and killed it, too, through no fault of the driver. This must have been so because a gendarme standing by said so.

We'd all like to have that \$500 runabout of our dreams, and most of us won't care whether its American, French or German. It will be a good thing to have, but to expect France to draw her supplies of this class of vehicle, or any other, "tout entière" from America is indeed a beautiful dream.

Meantime American automobilists and American machines are increasing in numbers and favor in France; the former are very much liked and the latter are usually highly praised. So now! This is the point of view of another American automobilist living in France who signs himself,

FRANCIS MILTOUN.

Moret-sur-Loing.

AFTERMATH OF THE HARRISBURG RUN.

Editor THE AUTOMOBILE:

[760.]—During the recent endurance run of the Motor Club of Harrisburg the speed ordinances were observed by the contestants, but there were plenty of grafters in the small towns and boroughs. Manheim, Lancaster County, had a very enthusiastic gentleman, who never owned an automobile but who got very busy and took the numbers of all he could, and the town is now reaping the benefit of \$10 apiece from the contestants.

The fortunate thing for the operators is that each car had an observer, whose duty it was to record the speed of the car on which he was observer. This was done, and the Motor Club of Harrisburg promises a very exciting deal with the Manheim people as the outcome of the arrests.

Many of the towns along the way were wide open, and a great many suspended business in factories and stores while the contestants passed through, giving them a hearty welcome. It is no doubt best for a tourist passing through Manheim to leave his car on the outside of the borough limits and walk through with his numbers properly displayed in front and back of him, to avoid arrest.

A CONTESTANT.

Philadelphia.

A TIP FOR THOSE WHO TOUR TO DELAWARE

Editor THE AUTOMOBILE:

[761.]—Herewith please find a clipping from the "Blarestown Press" which should be read by automobile tourists who have in mind visiting the famous Delaware Water Gap and the Pocono Mountain country.

A SUBSCRIBER.

Portland, Pa.

From the "Blarestown Press": "The authorities at Portland are again active in watching for automobiles without a Pennsylvania license that cross the river from Columbia for the run to the Water Gap and up the Pike County road. Last summer the borough collected \$300 in fines. On a recent evening an autoist crossed over to Portland, and Constable Pensyl, noticing that the machine did not carry the required license number, put the driver under arrest. He said he would stay over night at one of the hotels and then borrow enough money next morning to pay his fine. The constable went home and to bed. The automobile man also went to bed, but he did not sleep as soundly as the constable; anyhow, when the constable came around in the morning the tourist had hid himself over the river and back to Jersey."

A TIP FOR DELAWARE WATER GAP TOURISTS.

Editor THE AUTOMOBILE:

[762.]—I am much interested in the American Gold Cup tour through Europe this season, and would like to have the names of the firms entering cars for the competition.

I recently made a report for the Department of Commerce and Labor concerning the tour, and the interest being taken in the event by European manufacturers and autoists. As a result of that report I have had a number of inquiries from interested parties concerning American cars, and requests for the names of those competing in the tour. I believe it will result in much new business for American manufacturers.

Lucerne, Switzerland. R. E. MANSFIELD, American Consul.

MORE ABOUT BATTERY CONSUMPTION WANTED.

Editor THE AUTOMOBILE:

[763.]—Not long ago numerous letters appeared in "The Automobile" on the subject of battery consumption, many of them bringing out some very interesting points to me—and I have no doubt to a great many other car users as well. From the tone of some of the letters I thought the subject was up for a thorough threshing out, but somehow or other it appears to have been sidetracked for some unknown reason.

W. R.

New York City.

MODEL XIX, 50-HORSEPOWER ST. LOUIS TOURING CAR.

THE "St. Louis 50" has earned for itself an enviable position in the automobile world, and this distinction has come to the builders of "Rigs that Run," largely by their original and unique methods of construction. During the fourteen years the St. Louis Motor Car Company has built autos the aim has been to produce the best possible in construction and workmanship, and a careful study of the progress made shows how well this aim has been accomplished. Fourteen years ago this industry was given birth in a small shop of very crude nature (25x40 feet) in Nashville, Tenn., with John L. French as its originator and head. After many experiments, test trials, etc., the first rigs were placed on the market, and these models proved such a decided success that the company was encouraged to broaden out. The shop was increased from time to time until to-day the new factory at Peoria, Ill., covers a space of about two acres and a working space of 150,000 square feet, employing 350 men by day and 200 at night. In originating the much lauded integral system, three-point suspension and direct drive, the St. Louis is claimed to have been six years in advance of any other manufacturer in the automobile field.

In order to meet the varying requirements of autoists generally as expressed by the current demand, for the present year the St. Louis line consists of three models, variously known as Types 17 and 18, and Model XIX., which is also known as the St. Louis

heavy touring car. This car is equipped with a 50-horsepower motor of special design that is built from beginning to end in the home factories.

Motor Design.—The cylinders are cast in pairs with oppositely disposed valve pockets, all the valves being mechanically operated, while the reduction gears for the camshafts and the auxiliary driving mechanism are all enclosed in a neat aluminum housing. Particular attention has been paid to the matter of accessibility, to which end almost the entire sides of the crankcase are made to open by means of readily removable plates, exposing the crankshaft and connecting rod ends for inspection and adjustment. The crankshaft is of special steel, and is offset from the cylinder centers in order to minimize side thrust against the cylinder walls on the explosion stroke. The main bearings, which are of substantial dimensions, are of a specially alloyed bronze.

The motor accessories are of standard types throughout, ignition being of the high-tension type, using accumulators as the source of current, while the carbureter is of the automatic compensating type. A honeycomb radiator of special sectional form, permitting of easy repairs in case of damage, serves for cooling, supplemented by a gear-driven circulating pump. The essential

INLET SIDE OF THE ST. LOUIS 50-HORSEPOWER MOTOR, SHOWING ITS SIMPLICITY.

SUPERIMPOSED ARRANGEMENT OF GEAR-SET SHAFTS. E!

of lubrication is taken care of by means of a large supply tank placed on the forward side of the dash under the bonnet, communicating with a force-feed oil-pump, which passes the oil through a number of sight feeds on the dash.

Transmission.—In accordance with current practice on the highest grade cars, a multiple disk type of clutch is employed, in connection with a sliding pattern of change speed gear with selective operation. Final drive is by propeller shaft, the relation of the various essentials of the transmission from the motor to the rear axle being so designed that with the normal load aboard all are practically in line on the same plane, any slight differences due to inequalities of the road being compensated for by the universal joints in the cardan shaft.

The frame is of the usual channel section pressed steel, supported on semi-elliptic springs forward and scroll elliptics in the rear, the spring dimensions being 2 inches wide by 40 inches long, each spring having 8 leaves. Thirty-four-inch wood wheels of the artillery pattern constitute the running gear and are shod with 34 by 4 1-2-inch tires of any standard make. Two sets of brakes are provided, both being centered in special drums on the driving wheels, and constituting a set of internal expanding and external contracting bands acting on the inner and outer faces of the drums, the usual method brake operation being employed. The body is designed along modern lines and is very roomy, having a seating capacity of seven with the addition of two extra revolving seats in the tonneau. All on, the car tips the scales at 2,600—a very moderate weight for its power.

Models 17 and 18.—The model 18 St. Louis has as its groundwork a 35-horsepower chassis, embodying all those features of modern design that distinguish the up-to-date car, and is intended to meet the very general demand for a moderate-powered and moderate-priced car, that is not lacking in any of those essentials of design or detailed refinements usually asso-

ciated with very high-priced cars. Model 17 is the same chassis equipped with a runabout body designed along attractive lines.

The power plant is of the unit type, in that the motor, clutch and change speed gear are housed together, the whole being supported on a three-point suspension, a feature of design which the builders of the St. Louis cars were among the first to take advantage of. The motor cylinders are cast in pairs, the valves all being placed on one side and operated from a single camshaft. The same degree of accessibility which characterizes the larger motor is also prominent in this, and every part is easy to get at. The ignition system is of the high-tension type, using accumulators, while lubrication is by means of a force-feed pump, combining the essentials of simplicity and reliability in the highest degree. Particular attention has been devoted to simplifying the ignition and piping connections, and the absence of unnecessary wiring or pipes is noticeable, while both the manifolds have been designed to be readily removable in half the usual time. The main bear-

SIMPLE DETAILS OF THE MULTIPLE-DISK CLUTCH.

ings are accessible in a few seconds, as both the handhole covers may be removed by loosening a single bolt. The wheelbase of the car is 108 inches, and the tread is standard; with all on, the weight is 2,300 pounds.

One of the great advantages accruing from the use of the integral or unit form of construction for the power-plant and gear-set is the fact that all the mechanism is placed forward of the footboard of the driver's seat. A sliding type of gear-set is employed, providing three forward speeds and reverse. The pinions are made of special steel, with faces of liberal width, and proper beveling to insure an easy entrance in gear changing. All gears are locked by an automatic device, and cannot be stripped in changing from one speed to another.

CHASSIS OF THE "ST. LOUIS FIFTY" VIEWED FROM EXHAUST SIDE OF MOTOR.

MECHANICALLY the 1907 Renault chassis has undergone few changes, all the features which contributed to make the output of the Billancourt factory such a huge success last year being retained, with a few modifications in detail, in the models which made their appearance in this country only a few days ago.

As will be seen from the illustration, the suspension of the two larger models, 35-45 horsepower and 20-30 horsepower, has been changed, three-quarter elliptic springs being now employed in place of the longitudinal and transverse rear spring. On the smaller models the older type of suspension is still retained.

The four cylinders are cast in pairs, the crankshaft has three bearings, and all valves are mechanically operated by a single shaft, with cams integral. The pistons of the 35-45 horsepower Renault have four rings, three on the upper part of the piston and one on the lower part, the latter serving to clean the cylinder walls of lubricating oil, consequently keeping the valves and plugs in best condition. Ignition is as last year, by high tension Simms Bosch magneto, placed at the front of the motor and driven off the camshaft, all the gears being completely enclosed within the crankcase. This year's magneto is rather smaller than that employed on previous models. There is no advance or retarding spark mechanism on the Renault models, the magneto itself automatically giving the advance in proportion to the speed of the motor. The only modification in the carbureter is that the larger models

are now fitted with the small regulator on the dashboard, which has been a feature of the Renault cabs from their introduction, and by means of which the speed of the motor is regulated. The distinctive feature of the Renault system is that the mixture instead of being formed in the carbureter itself takes place in a chamber at the extremity of the intake pipes, and close to the inlet of the motor. The great advantage of this automatic carbureter over those generally employed consists in the fact that it is entirely metallic and does not comprise any membrane, piston or valve, the fragility of which is often a cause of annoyance. Engine control is unchanged by the modification to the carbureter, being, as before, by accelerator pedal and lever under the steering wheel.

Nothing is under pressure in the Renault, consequently there is a simplification of the motor unknown to most automobiles. If any further justification of the thermo-syphon system were needed it is found in the performance of the Renault car, which won last year's French Grand Prix, an event which, more than any other, tested the water-cooling systems of the motor. In addition to being exceedingly simple, the radiator again the dashboard gives the maximum of accessibility to the motor. A fan is combined with the flywheel and assures a constant passage of air around the vertical tubes. In the transmission everything remains as on the previous year's model, a leather-faced cone clutch sliding gear transmission giving four speeds forward and reverse.

VIEW OF CHASSIS FROM THE REAR.

CHASSIS AS SEEN FROM FRONT END.

A NEWCOMER FROM THE WEST: THE C. F.

CHICAGO is coming along as an automobile manufacturing center, the latest car to claim the Windy City as its birthplace being the C. F., made by the Cornish-Friedberg Motor Car Company, 1233 Michigan avenue. This newcomer to the ranks of automobiles turned out in the middle west is designed to cater to the large demand for a car with a four-cylinder vertical engine

THE C. F. 30-HORSEPOWER TOURING RUNABOUT FOR 1907.

as well as numerous other features only to be found in the higher-priced cars, and is listed at the low figure of \$1,750, complete. The motor cylinders are cast in pairs and their dimensions are 4 1/4-inch bore by 4 3/4-inch stroke, the motor developing 30 horsepower at a moderate normal speed. The cylinders are cast of special iron and the crankshaft is of nickel steel, somewhat of an innovation being found on the latter in the provision of oil rings on the main bearings. All the valves are placed on the same side of the motor and operated by a single camshaft, at the rear end of which it drives a vertical shaft through bevel gearing. The pump is located on the lower part of this shaft, while at its upper end it carries the ignition timer. All the reduction gears are completely encased in an aluminum housing. The lower half of the aluminum crankcase only serves as an oil-pan and is readily removable to permit of the inspection of the entire interior of the motor. In addition to the splash lubrication provided by the supply of oil in the crankcase, a mechanical force-feed oiler is used, with nine independent leads, insuring a positive supply of oil to all the important points as long as the motor is running. The oil passes through the multiple sight-feed tubes on the dash.

Ignition is by the high-tension system, employing a multiple-unit Splitdorf coil mounted on the dash, and a four-point roller contact timer, which, as already mentioned, is mounted vertically just forward of the dashboard, thus minimizing the amount of wire necessary. The regular equipment of the car includes a set of accumulators for service running and a set of dry cells as a reserve. The essential of cooling is taken care of by a fin tubular radiator, supplemented by a fan mounted on ball bearings, circulation being maintained by a gear-driven pump. Parsons white bronze is used for the engine bearings, which are unusually liberal-sized, the flywheel and main bearings measuring 5 inches in length, while the center bearing is 3 inches and the forward end bearing 3 7/32 inches. The entire engine is protected from beneath by a sheet-metal dust pan.

In order to render the car as simple and as nearly fool-proof as possible, a planetary type of change-speed gear is employed,

providing two forward speeds and reverse. The pinions are all of specially hardened nickel-steel and care has been taken to render the gear as nearly noiseless as possible, even when working on the low or reverse. Final drive is propeller shaft, the latter being of special steel, 1 1/4 inches in diameter and provided with Blood Brothers universal joints at both the axle and transmission ends. The front axle is of tubular steel construction, roller bearings being employed on the front wheels and also on the rear axle and wheels. The groundwork of the chassis consists of the usual channel-section type of pressed steel frame supported at all four points by standard semi-elliptic springs of liberal dimensions. The wheels are hickory, of the artillery type, and carry 12 spokes in each wheel; they are 32 inches in diameter and are shod with 3 1/2-inch Diamond wrapped tread tires on Marsh quick detachable rims. Two independent sets of brakes are used, both being centered in drums on the driving wheels and both operated by pedals, so that there is only one side lever. The steering gear is of the irreversible type and is provided with ample bearing surface throughout to prevent rapid wear and consequent looseness. Throt-

tle and ignition levers are mounted on a stationary quadrant placed over the steering wheel, the latter moving independently of the quadrant. The gasoline capacity is 20 gallons.

An attractive straight-line body with a seating capacity of five persons is used on the touring car, and a regulation type with jump seat on the runabout. The latter has a wheelbase of 108 inches on a standard tread, so that the rear seat of the tonneau is not only amply wide but there is also plenty of leg room for the passengers, something that is not always the case on the low-priced car. The standard finish is Brewster green, or red with black trim, but cars will be finished to specification when desired. The regular equipment consists of a pair of acetylene headlights and generator as well as oil side lamps and tail-light and a complete set of tools.

It will be apparent, both from the accompanying illustrations

THE C. F. TOURING CAR, CHICAGO'S NEWEST ENTRANT IN THE FIELD.

of the newcomer from the west, as well as the description given of the various parts of its power plant and chassis, that the effort to produce an up-to-date car to list at a very low figure has been unusually successful. Standard engineering practice has been followed throughout the design and construction, high-grade materials are employed and the general appearance of the car itself leaves nothing to be desired.

THE MODERN ART OF TREATING STEEL

By ALBERT E. SCHAFF, MANAGER POPE MOTOR CAR CO.

THE advance in the art of automobile building cannot be better illustrated than by taking up one leading topic in reference to the manufacture of the new alloy steels, which has marked an epoch in the art in the past two years. But a few years ago the automobile manufacturer had available for his use only low-carbon steels, which have been considered, and are considered to-day by most manufacturers, as quite good for the purpose. These low carbon steels, ranging in carbon from twenty to forty-point, greatly simplify manufacturing operations, since they require almost no treatment in their handling. No special annealing would be necessary in the drop-forging after leaving the hammer, and they could be then machined at high speed, running as high as ninety feet per minute; and, if the part in question were a gear blank, after the cutting of the teeth, the gears could be case-hardened by the ordinary simple process without the aid and great care required when the pyrometer is brought into use.

The price of this steel generally ranged between two and four cents per pound. It will be seen from this that the total cost of material and the labor was comparatively small. The steel itself gave but very little range in treatment. Its tensile strength was neither lowered nor increased materially by any treatment that could be resorted to. Hence the manufacturer had little opportunity to exercise his skill in the nice engineering of the various parts to secure suitable strength.

Vastly Greater Cost of Alloyed Steels.

When we come to chrome-nickel steels, we find at once a material that lends itself to a wide variety of uses. Arriving at the plant in the raw, unannealed state, at a cost anywhere from 20 cents to \$1.20, it will have to be annealed; and this process, conducted with but very little latitude in the degrees of heat, must be continued for some ninety hours, and as carefully cooled. It is then ready to be machined at a cutting speed of about thirty-five feet per minute. After machining, the piece goes to the hardening and tempering department, where it receives a series of careful treatments, varying according to the use to which the part is to be put.

To illustrate, two examples will be given; but, before doing so, it might be mentioned that chrome-nickel steel has a range of treatment which enables one to get from the same piece a tensile strength of only one hundred thousand pounds, with an immense deflective range, *i.e.*, by cutting the ultimate strength down, the piece is made so soft as to be able to bend almost double, like a hairpin, without breaking, thus making it suitable for places where vibration might attack and crystalize the metal. Or this same piece, if used in some place where immense resistance to torsion or direct shock is necessary, could be treated to give a strength of 250,000 or even 300,000 pounds tensile strength; but in the latter case it would be at the expense of the qualities just mentioned, and the metal would be hard and yielding, so that while it would stand an immense amount of stress in steady pull; on the other hand, if subjected to intense vibration, it might readily break—a characteristic to be avoided.

Of the two examples referred to above, we will take up the pivot-axle upon which the front wheels are mounted. Anyone will readily see that the safety of the occupants of a car depends not altogether upon the strength contained in certain parts, but upon its life. All metals are strong enough, as a general proposition, to resist the shock of an accident; still, most of them, if highly treated, will quickly succumb to the disintegrating strains of vibration. Therefore, a pivot-axle should be treated to give a low ultimate tensile strength with a low elastic limit in order that the metal should not be in such high tension as to be subject to attack by vibration. Automatically the metal is in a more mild condition and can be bent in a number of alternating directions before showing any damage to its fiber. Such a piece would

naturally more readily bend than that which is treated for a higher tensile strength; but at the same time it would be safer to have the piece in a condition where it would bend than where it would break.

Painstaking Care Necessary in Every Operation.

To get the results above described in the pivot-axle, the steel, when received from the manufacturer, is very carefully forged at a very low heat, being struck an innumerable number of light blows, with the temperature range of only about one hundred degrees. This means quick cooling and constant reheating, and reduces drop-forging almost to a hand-forging process, with the advantage, however that the metal, by being formed in dies, is given a better shape. It is next annealed very carefully, and when machined it is reheated, hardened and tempered. The treatments vary considerably from those of transmission gears, as we are aiming to get a tensile strength of about 110,000 pounds to the square inch, with a large deflective movement. In all of these operations of heating, quenching and drawing, pyrometers must be used, as the variation must not exceed 30 degrees, and the temperature runs as high as 1,450 Fahrenheit, it will be seen how carefully these operations must be conducted to produce the exact results required.

We now come to example No. 2, the forging and treatment of transmission gears. In order that the modern automobile may be made to yield the greatest power per pound of car weight, all the details must be carefully studied or a very heavy car with heavy wear on the tires and all moving parts will result.

The transmission gear being subjected (with the modern disc clutch) to small shock and very heavy torque, having most of its strains come upon one, and at best not more than two teeth at a time, must be given a treatment that will yield a very high tensile strength of, say, 225,000 pounds to the square inch, with a corresponding increase in its elastic limit. Although the steel for this purpose might be exactly the same base as used for the pivot-axle just illustrated, still a treatment is given to yield 225,000 pounds tensile strength. Instead of the piece being capable of bending almost double without breaking, it would probably bend but few degrees before it would yield.

Different Treatment Required for Various Parts.

However, the conditions to be met are so different from the case of the pivot-axle that it is highly desirable to give it this treatment, since the part must be made to resist an immense amount of strain without yielding in the slightest degree. After it is machined and the teeth cut, the gear must be carefully treated so that it will not warp, as these high-class alloyed steels are much more sensitive in this respect; the treatments in number are about the same as for the pivot-axle, excepting that they are carried higher and drawn less. The amount of carbon in the steel itself is a determining factor, to an extent, as a variation of even two points would naturally lower or raise the number of degrees of heat to be applied in the various operations. An even greater degree of watchfulness would be necessary where a high treatment is to be given, in order to confine the temperature variations within the closest possible limit.

When it is remembered that in the high-class motor-car steels elaborate treatments have been resorted to to meet the varying conditions in the steel itself, it will be seen how complex the problem becomes by the adoption of these chrome-nickel steels, some of which come with 35-point carbon, some 50, and others but 40. The old form of guessing the proper heat by the eye and holding the piece in the dark and determining the temperature by the color must absolutely be discarded if success in their use is to be had, as success can only be obtained by the adoption of new methods and skilled help.

THE DEATH OF ALBERT CLÉMENT.

A road accident, details of which the laconic cable messages from France fail to supply, has cost the life of one of the most brilliant of the world's racing drivers. Albert Clément was practicing on the Dieppe circuit on one of the six-cylinder racers which the firm constructed last autumn, when, in taking a curve at the village of St. Martin-en-Campagne, a few miles from Dieppe, the unfortunate accident occurred. Venus, who usually acts as mechanic for Clément, had been replaced by Gauderman, a close friend of the family, and a young racing driver of promise, who only entered the Bayard-Clément factory last year, and whose injuries are fortunately reported to be only slight. It would appear that a comparative test was being made of four and six-cylinder machines, for the firm has for some time been experimenting with six-cylinder engines, with the intention of putting a touring six on the market, and last fall built three powerful racers of this type, which have not yet been tested in any important event. The accident took place on the eve of the closing of the course to racing automobiles, the Automobile Club of France having sent forth an order that from the follow-

ALBERT CLÉMENT SHORTLY BEFORE HIS UNFORTUNATE END.

ing day until three weeks prior to the race no machine should be allowed to travel over the circuit at more than twenty miles an hour, in order that the surface might not be spoiled.

Albert Clément was the eldest son of Gustave Adolphe Clément, the head of the great Bayard-Clément factory at Levallois, near Paris, and Mezieres, in the Ardennes. The elder Clément, less than thirty years ago a modest mechanic and repair man, without wealth and with few material prospects, is to-day one of the richest men in France, and his son, had he lived, would have inherited a large fortune.

In the Ardennes circuit of 1904, Albert Clément made his first public appearance in an automobile race of any importance, when he captured first place with a voiturette from the parental factory. In the same year he created a sensation as the boy driver of the Vanderbilt race, in which event he lost first position to George Heath on a Panhard by less than two minutes. His performance was the talk of the race, for young Clément, then only nineteen years of age and of very youthful appearance, proved himself the equal of the most skilled automobile drivers of the world. The following year, in the French elimination trial for the Gordon Bennett contest, Albert Clément started fourth, but had to withdraw on the second round with a cracked cylinder. Owing to the imperfectly organized telegraphic service, no news of the young driver could be obtained for several hours, and it was only when Clément walked into the stand, having tramped over the mountainous country, that the anxiety of his parents and friends witnessing the race was relieved. In 1905 the Bayard-Clément team was not selected for the Vanderbilt contest; Albert Clément's public automobile

performance consisted of a dead heat with Hanriot on a Darraq light-weight racer on the Gaillon Hill.

Last year Albert Clément finished sixth in the Ardennes race, third in the Grand Prix and fourth in the Vanderbilt Cup. His performance in the Grand Prix will be remembered as one of the most brilliant and fascinating automobile races the world has ever seen. At the end of the first day Szisz was first, Albert Clément second, and Nazzaro third, fifteen minutes behind the young Frenchman. For over six hours the young Italian and the young Frenchman raced neck-and-neck around the course, Nazzaro seeking to shake off the fifteen minutes lost on the first day, and Clément doing his utmost to keep his rival in third place. None who witnessed it will forget the scene at the commencement of the last round but one. In his excitement Albert Clément overshot the gasoline station, and had to come back on reverse gear. Nazzaro was only a minute behind. Filling the gasoline tank by the ordinary feed pipe was too slow, and Albert yelled for the big cans to be handed over to him. One by one he emptied them into his tank, spilling the dangerous fuel over the car with the recklessness of a man who has reached the point when he must abandon all reserve. Never was a car loaded up with such rapidity, the youthful driver and his diminutive mechanic, Venus, displaying strength and agility that one would never have credited them with. At the commencement of the last round the Italian rushed by the grand stand only one minute behind Clément, and succeeded in capturing second position by a little over three minutes. Had Clément not persisted in his objection against dismountable rims he would in all probability have won the race.

At the time of his death Albert Clément was undergoing his three years' military service, from which he would have been released after the maneuvers of this summer. He was stationed at Vincennes, near Paris, and had obtained three days' leave to practice on the Dieppe course. Only a few weeks ago he had been refused leave of absence for the Targa Florio, and had very sorrowfully to abandon his place to his friend, Gauderman. In character, Albert Clément bore a close resemblance to his father, often spoken of as "the automobile king of France." Of a somewhat retiring disposition, quiet and thoughtful, there was under the unemotional exterior not usually associated with the French character, a genial nature, a ready wit and a strong individuality which won for him friends on every hand. Albert Clément is survived by a younger brother and two sisters, the younger of whom was married a few weeks ago to Ferdinand Charron, head of the C. G. V. firm, and also a successful competitor in early international automobile races.

MOTOR TRACTION IN GERMANY.

In the *Archiv für Eisenbahnwesen*, Vellguth has published a careful study of the costs of automobile traction. As regards the omnibus service in towns, he comes substantially to the same conclusions as did E. Manville in his discourse before the Automobile Club; but he is more pessimistic, says *Engineering*. In Germany, motor-omnibuses, he thinks, could hardly pay their way in towns of less than two million inhabitants, which means that Berlin alone could reckon upon such a service. Vellguth would not appear to make sufficient allowance for general and technical development, however. The cost of building the cars, of oil, tires, and working expenses will be diminished with increased number of vehicles, and longer experience will enable us to construct cars of longer life. As regards the omnibus service on the high roads, Vellguth may be more right in his verdict. One of the lines he deals with has a length of more than thirty miles; this Partenkirchen line is worked only in summer, however. On the whole, a light railway, driven by benzene motor cars, would be more promising than the omnibus, which transports only passengers, not goods. Vellguth gives a detailed estimate for the construction and working of a light railway of twelve kilometers (7.5 miles) length. Such a line would probably be more useful for agricultural and industrial districts than a mere passenger conveyance.

GRAND PRIX PREPARATIONS UP-TO-DATE.

PARIS, May 13.—Building operations have begun on the grand stands for the Grand Prix, and will be pushed forward with considerable activity. In order that the road surface may not be ruined by the rapid passage of racing machines and fast touring cars, the Sporting Commission has taken stringent measures. From Saturday next none of the racers engaged in the Grand Prix will be allowed on the course under penalty of disqualification, and the speed limit of eighteen miles an hour in open country will be rigorously applied to all touring cars. Three weeks before the race the course will be again opened to racers between 4 and 6 A.M. only. Racing drivers are taking advantage of the last days of liberty, and hardly an hour passes in the forenoon without the passage of some flyer at top speed. Le Blon has just come up from Nice on a 100-horsepower Panhard with Sider resilient wheels, which it is rumored will possibly be used in the race. Heath is out on his 1907 Panhard. Wagner, Lamberjack and Zedel are exploring the circuit on a Fiat touring machine, and Garcet is training with a new Bayard-Clément racer.

Speculation is rife as to the make-up of the Darracq team in the Grand Prix, as the result of the departure of Wagner. No official announcement has been made by the firm, but it is exceedingly probable that the machines will be handled by Hanriot and Demogeot, and that Caillois, who was to have steered a Commission Sportive racer, will take the place of Wagner on one of the more powerful machines. Rigal, who piloted a Berliet in the Targa Florio, will take the place vacated by Caillois.

In anticipation of an inrush of English visitors for the Grand Prix, a special agent of the *Service des Mines*, has been appointed at Dieppe to hold examinations and grant driving licenses to foreign visitors with the least possible delay.

FRENCH CLUB'S TOURING CONTEST UNITES 26.

PARIS, May 14.—Twenty-six machines are engaged in the only touring competition organized directly by the Automobile Club of France this year, under the double title of the Criterium of France and the Press Cup. The former is a touring event pure and simple, serving to eliminate machines for the final speed test to be run on a circuit near Trouville, with a limited fuel allowance. For one month more engagement may be sent in at double fees, but it is not likely that many firms will avail themselves of the privilege. Twenty-six cars are sufficient to assure the success of the contest, but are not sufficient to give to the event all the importance its promoters had hoped to secure for it. The complete list of entrants at ordinary fees is as follows:

- | | |
|-------------------------|--------------------------------|

FRENCH ROUND-THE-WORLD AUTO SHOW.

PARIS, May 12.—There seems every possibility of the French floating automobile exhibition being carried through to a successful issue. The suggestion was made a few months ago that a large steamship should be fitted up with a representative collection of French automobiles and parts and sent on a voyage round the world, calling at all the important ports, and staying at each from one to eight days, according to the possibilities of doing business. The device adopted by the organizers of the scheme was to visit the largest number of important ports in the shortest possible time. The cooperation of the French consul in each

port visited will of course be secured, and a considerable amount of advertising done prior to and during the stay of the floating exhibition. Starting from Marseilles on a date yet to be fixed, the vessel will pass over to Algiers, call at Lisbon, then cross the Atlantic for Montreal, where a stay of six days will be made; Quebec will be given a three days' visit and Halifax may examine French automobiles for two days. American seaports to be visited are Boston, New York, Philadelphia, Baltimore, New Orleans and Galveston, New York being accorded eight days. Thirteen South American ports will receive a visit from the exhibition ship; two on the Pacific coast of North America; three in Japan; two in China; three in French Indo-China; three in British Indo-China; five in Australia; four in India, and finally Port Said, Alexandria, Tunis, and Marseilles. Altogether, fifty-four of the most important ports of the world will be visited. The length of the cruise will be from sixteen to eighteen months, exhibitions alone being responsible for not less than 240 days. If it is considered necessary in the interests of trade the stay will be extended, or new calling points will be added to the list.

TWO-CYCLE OFFICIAL TESTS IN FRANCE.

PARIS, May 13.—Up to the present very little attention has been given by French automobile constructors to two-cycle motors, no engine of this type being sold in France in appreciable quantities. To encourage the development of the two-cycle engine, the Automobile Club of France has authorized the Technical Commission to hold a competition open to both French and foreign two-cycle motors, using any kind of fuel. The competition will take place in the club laboratory in October next, but engagements must be made and a complete description of the machine given, in French, not later than July 31. Entry fee is \$20 per motor. All engines must develop not less than eight, nor more than 24 horsepower, and angular speed of the motor must not be less than 800 nor more than 1,500 revolutions per minute at maximum power. The competition will comprise a six hours' test at full charge, a three hours' test at half charge, and a three hours' test without load, the motor running at the same speed as when under full load. One day will be allowed for fixing the motor on the testing blocks, the second day can be spent in preliminary tests, the third day they must undergo the six hours' test, the two other tests being taken on the following consecutive days. Awards will be based on the power developed and on the cost of fuel consumed per horsepower-hour corresponding to the maximum of power. One hundred points will be awarded to the motor having the lowest consumption per horsepower-hour, and the same number of points to the motor developing the greatest proportion of power, the others receiving a number of points in degressive proportion.

FRENCH CLUB PROHIBITS SPEEDING.

PARIS, May 14.—Twenty-eight hours fourteen minutes is the record time in which the 1,500 kilometers separating Paris from Madrid have been covered by automobile. Sorel, an Anglo-Indian driver of much experience in racing events, established the record on a Lorraine-Dietrich, the start being made from near the Porte Maillot, Paris, and the finish in front of the Royal Automobile Club at Madrid. The average speed was 34 miles an hour, a marvellous record for such a distance.

This will be the last of the many attempts that have been made by automobile manufacturers during the last few weeks to establish record runs across France on unprotected roads. The Automobile Club of France having decided to take severe measures against firms indulging in such runs. Prohibition was imposed on the request of the British Automobile Club, English firms having been very active lately in making fast runs from London to Monte Carlo for advertising purposes. Generally the machines left London in the morning, crossed the Channel by a fast boat, and rushed from one end of France to the other at a speed which would not have been tolerated in the British Isles.

AUTOS SHOWED A LA HORSE FOR BLUE RIBBONS

PHILADELPHIA, May 20.—Fashionable Philadelphia must be given credit for having discovered and carried through to a successful conclusion a new wrinkle—an automobile carnival on the well-known lines of the horse show. As the prospectus of the affair put it, the show's object was "to bring to the attention of the trade and the thousands of automobile owners in Philadelphia in a practical manner and assist in bringing about the adoption of certain styles of carrosserie and appointments for specific

gowns without fear of buttings in on the part of J. Pluvius. The air was so balmy that the filmiest confections went.

The judges, with a swarm of two score "stewards," who stewarded not, to add éclat to the occasion (like the vice-presidents at a political meeting) finally began to throw off decisions in vast numbers. The program called for about ten minutes' work on each class. The majority of the twenty classes took considerably longer, so that at 6 o'clock the officials were awarding ribbons in

the class scheduled for 4:35. When, at 7:25, there was still one class to go—owners' electrics—and the grandstand was almost empty, the officials held a short council of war and decided to call it a day's work—and it was a hard one, too.

There are possibilities in the new game—undoubted possibilities. The eagerness with which contestants and spectators awaited the judges' decisions indicated that. Manufacturers' representatives and newspaper men were keeping tabs on the rising scores of their favorites and registering quiet kicks at adverse rulings, all of which goes to show that there was no lack of interest. The next affair of the kind—and the promoters aver that there will be another next year—will benefit by

THE INVITING FLORAL BRIGADE.

purposes and aid in determining a basis of what is and what is not necessary and in good form."

It was to see this theory demonstrated that possibly three thousand local automobile enthusiasts assembled at the Belmont Driving Park, Saturday afternoon, and patiently sat through a much-too-long program of events in which speed was a negligible quantity, and in which "appearance, appointments, and suitability for the work designated" were everything.

And the bold innovation was voted a success! True, the scions of aristocracy who conducted the carnival started operations over an hour behind the appointed time, and forgot lots of necessary trimmings. But "everybody" was there, and paid good money to be there. Everybody who could help was asked to help, for the object was a charitable one—to raise much-needed funds for the Pennsylvania Epileptic Hospital and Colony Farm. Result: Upwards of \$5,000 net for the worthy charity!

Such a gathering of the Quaker automobile clan was never before seen. Besides the more than 150 contesting cars—there were 220 individual entries—the incoming machines became so numerous that the paddock, the infield, and the backstretch were perforce used for parking purposes—at \$2 per. Really, the scene out-Wissahickoned Wissahickon at its Horse Show best. And the day was of the kind which permitted the display of new

THE COURSE AS IT LOOKED FROM THE CAPACIOUS GRANDSTAND.

the experience of the promoters of this one. Things will go smoother.

Aside from the Stoddard-Dayton in the runabout classes, and the Packard in the touring car section, no one car made a decided hit. The Stearns did get three blue ribbons, it is true, but nothing else, while the Pierce Arrow gathered ribbons in nine events, as did the Packard, but the latter had four blues among its plunder. The Stoddard-Dayton really was the hit of the show, getting inside of the money no less than eleven times—three blues, four reds, one orange, and three white ribbons. The Baker made nearly a clean sweep in the electric class, while the Mercedes led the foreign cars.

Miss Frances C. Griscom registered a double win in the ladies' obstacle and ladies' time races. Many a paid chauffeur could learn car kinks from that young lady, who can make her Royal Tourist do everything but talk. The only other lady to win a first in the various classes was Mrs. George M. Costello in her Stoddard-Dayton, which cleaned up a big field in the under \$2,500 runabout class.

The automobile "show" is a fixture.

The Score for the Afternoon.

The newspaper men present endeavored to arrive at a comparison of the afternoon's results by scoring points as in the intercollegiate championships—5 for firsts, 3 for seconds, 2 for thirds, and 1 for fourths. On this basis the results of the contests figure out as follows:

Cars.	1sts.	2ds.	3ds.	4ths.	Total Points.
Stoddard Dayton	3	4	1	3	32
Packard	4	3	1	1	32
Pierce Arrow	1	2	4	2	21
Stearns	3	.	.	.	15
Pennsylvania	2	.	1	.	12
Royal Tourist	2	.	2	.	10
Locomobile	1	1	.	2	10
Mercedes	1	.	1	2	9
Baker electric	1	1	.	.	8
Thomas	.	1	2	.	7

A. L. A. M. ANNOUNCES EDUCATIVE SCHEME.

A big scheme is on foot at the offices of the Association of Licensed Automobile Manufacturers to organize a library and central clearing house, where information on every phase of the automobile industry throughout the world will be available for ready reference. Every known automobile and engineering publication in America and Europe has been subscribed for and will be kept permanently on reference in the club library. Each week the contents of every magazine will be indexed and cross indexed in such a manner that a person desiring information on any given subject having been treated in magazines or newspapers will find it readily to hand. All articles of interest in the foreign publications will be translated into English and a summary of the world's automobile literature will be compiled and published in a weekly review which the Association intends to produce at an early date. The magazine, which will be supplied to all members of the A. L. A. M., will give condensed reports of articles of interest, with reference to the periodical in which the matter originally appeared, in order that those interested may readily obtain more detailed information when desired. H. T. Clinton informed THE AUTOMOBILE representative that a couple of editors would be appointed to take charge of the library and the magazine, and that a competent staff of translators would be set to work at an early date. The new department will be under the supervision of Coker F. Clarkson.

BALTIMORE'S CLUB WILL INVESTIGATE.

BALTIMORE, May 20.—The Automobile Club of Maryland has started a rigid investigation into the methods used by the country police in ascertaining the rate of speed of the automobiles. The investigation was the outcome of several complaints made by citizens who claim that they were unjustly arrested in the county on the charge of unlawfully speeding their automobiles. Advertisements have been inserted in the local papers requesting all who have been arrested in the county to make a full report of the circumstances attending their arrest.

CONCISE, SIMPLE RULES FOR 200-MILE RUN.

In formulating regulations for the 200-mile endurance run of the New York Motor Club, to be held June 6, the committee in charge, of which R. H. Johnston is chairman, has taken considerable pains to make the rules as simple and as concise as possible, omitting all unnecessary provisions. It has been found by experience that the numerous superfluous provisions usually inserted in such schedules only result in confusing the observers and checkers, as well as the entrants themselves. The contestants will be required to cover the distance according to a definite time schedule, an observer being assigned to each car in order to take note of all adjustments, repairs and replacements.

The start is to be made from Columbus Circle, New York City, the usual route along the river being followed northward as far as Poughkeepsie, where a turn to the right will be taken through Amenia, Lakeville, Great Barrington and Lenox to Pittsfield, Mass. At this point the route practically doubles back on itself until Chatham is reached, where it again turns northward to Albany, the distance being slightly in excess of 200 miles. A pilot car will precede the run, distributing confetti.

The cars will be divided into two general classes, denominated A and B, the former consisting of touring cars, and the latter

SOME PICTURESQUE SCENERY IN THE BERKSHIRES.

runabouts, or, as the rule states, "having a seating capacity for two or three persons." All cars must be regular stock patterns, and a catalogue describing the type of car to be entered must accompany each entry. The entry fee will be \$25 for each car, and the lists will be held open at the office of Chairman Johnston at 1402 Broadway until the evening of June 3. In order to determine the order of starting a drawing will be held as soon as all the entries are in. Each entrant is to nominate an observer.

Instead of converting the run into a race right from the start, a car that loses time between controls will not have to make it up between subsequent controls, but will have its time of leaving the next checking point advanced according to the amount of time lost and continue according to the same schedule of running, but with the new time.

Rule 7, which covers the matter of penalties for repairs, replacements and adjustments, provides as follows:

Rule 7. Penalties.—Each observer shall keep a written record of all adjustments, repairs and replacements made on the car in which he is riding, and the exact time so spent. A penalty of two points shall be inflicted for each minute or fraction thereof spent in making adjustments, repairs or replacements. No penalty shall be inflicted for work of any kind done on tires, but the time spent in tire repairs shall not be deducted from the running time allowed between the various controls. Contestants will be allowed, without penalization, to fill with water, gasoline and lubricant, to turn up grease cups and to oil the machinery, but everything else done on the car, aside from the normal operations of starting and of operating, shall involve penalties as above stated.

The start will be made at 6 A.M., and the running time provides for the arrival of the first car at Albany about 5 P.M., so that there will be ample time for all of the contestants to finish before the leaving of the night boat for New York.

SPRING DOINGS AMONG THE AUTO CLUBS

Chicago Clubs Working with Trade for Orphans' Day.

CHICAGO, May 20.—With the combined force of the Chicago Automobile Trade Association, Chicago Automobile Club and Chicago Motor Club exerted to make the event an unqualified success, motorists predict that orphans' day, June 12, will be a memorable occasion. The chairman of the committees representing the three organizations have already met to compare notes and arrange for a general meeting of their committees.

Joseph F. Gunther of the Chicago Automobile Club, L. J. Ollier of the Chicago Motor Club, and Walter Githens of the Chicago Automobile Trade Association, found on discussing the plans which they had outlined individually that they were in practical unanimity as to the course to be pursued. The field will be carefully laid out, they said, so as to take in every institution of the city in which parentless lads and lasses abide, and, after a trip from some central point that will take in the different institutions, the route will be laid out by the most direct course to some amusement garden, where the youngsters will be stuffed with peanuts and candy.

Local preparations include the appointment of a committee by the Chicago Automobile Club, which will have entire charge of the entertainment of the guests so far as the Chicago Automobile Club is concerned. Charles E. Gregory is chairman of this committee, and his associates are C. A. Coey and Joseph F. Gunther. At the same time as these appointments were made the board of directors of the Chicago Automobile Club decided to apply for a sanction for a race meet on July 13, the Saturday the Gliddenites are in the city.

It also was reported to the directors that the recent spell of wet weather has upset the calculations of the contractors, and that it will be impossible to have the new home in Plymouth court ready for occupancy by May 30, the date set some time ago. Instead, the opening will take place some time between June 1 and 15. The wet weather would not permit the plaster to dry, it is said; hence the delay.

Tennesseans Reorganize and Elect Officers.

MEMPHIS, TENN., May 19.—Matters of much importance to local automobilism were transacted at the recent annual meeting of the Memphis Automobile Club. The club was practically reorganized along lines that will better insure the safety of pedestrians, and in like manner the drivers of cars and other vehicles. Rules and regulations were passed, such as will proscribe the reckless members to carefulness and legitimate use of the machines. A reasonable speed limit was set. Under the rules adopted by the club the members will be required to conform to the State and city ordinances. The result of the election of officers for the ensuing year was as follows: President, S. T. Carnes; vice-president, S. B. Anderson; secretary, C. S. Williams; treasurer, J. H. Stewart.

Activities of the Automobile Club of Kansas City.

KANSAS CITY, MO., May 20.—With a membership of nearly 100, the Automobile Club of Kansas City, of which W. W. Cowen is the president, and E. J. McNamara secretary and treasurer, is preparing for a busy season. A hill-climbing contest is scheduled for May 30; a club run will be made to Lexington the first pleasant Sunday in June, and on June 12, following the suggestion of the A. A. A. Board of Directors, the club will conduct an Orphans' Day. A race meet is to be the fixture for July 4. The club is an active member of the Missouri State Association of the national organization, and its influence is very substantial. The backward spring has somewhat subdued automobile enthusiasm, the weather having been cold, rainy, and altogether the worst for this time of year experienced in Missouri for many years.

Why Worcester Club Will Not Hold an Economy Run.

WORCESTER, MASS., May 20.—Worcester Automobile Club will have no economy run this spring. This was decided at a meeting of the board of governors Saturday night. Chairman Frank L. Murdock, of the special committee in charge of the plans for a run on the economy and endurance basis reported the plan as feasible, but the board decided there was not enough unoccupied time. The board considered the events at Readville and Wilkes-Barre, May 30; the New York Motor Club's run, June 6; Orphans' day, June 12, and other events scheduled to come between the present time and the start of the A. A. A. tour, and, in addition, took account of the Old Home carnival in Worcester, June 17-20, which will take up the time and attention of many of the clubmen, and decided to call off the run for the present.

The Worcester club has held gymkhanas each year for the past two years. This year there is a prospect there will be a gymkhana on a larger scale. Plans are being talked of which will result in teams from the Worcester club, the Bay State Automobile Association and the Rhode Island Automobile Club, of Providence, competing in gymkhana stunts in each of the three cities represented by the clubs. The winners will be figured out when all three events have been had and their scores tabulated.

At the meeting of the board of governors, Saturday night, Chief David A. Matthews, of the Worcester police department, was elected an honorary member of the club.

New Jersey A. & M. Club Committees Appointed.

NEWARK, N. J., May 20.—At a meeting of the board of governors of the New Jersey Automobile and Motor Club, held last week, the following committees were elected to serve the ensuing year:

House—Joseph H. Wood, L. T. Wiss, Dr. James R. English, W. C. Shanley, J. M. Byrne, C. W. Oathout, J. H. Dawson, H. T. Meyer, C. W. Baker, Theodore Mertz, F. A. Croselmir.

Legal—W. F. Kimber, J. H. Wood, James R. English.

Membership—P. E. Heller, G. H. Simonds, C. A. Westervelt.

Legislative—W. C. Crosby, Dr. H. Crittendon Harris, R. C. Jenkinson, Arthur Heller, G. E. Long.

Race—W. C. Shanley, J. W. Mason, H. B. Niblette.

Good Roads—J. H. Wood, W. J. Morgan, H. P. Cook.

An Excellent Plan of Holding Club Runs.

BROOKLYN, N. Y., May 20.—The Runs and Tours Committee of the Long Island Automobile Club has adopted an excellent plan for the holding of its club run. A rendezvous is appointed to be reached for dinner at a specified hour, and it is up to the participants to reach the place leisurely or do some traveling at the limit of legal speed. The committee consists of Charles Jerome Edwards, James Edward Bristol, and William Schimps. Yesterday's rendezvous was at the Hotel Gramatan, Bronxville. In announcing its runs the committee gives the exact route on a postal card. May 25 and 26 there will be a two-days' run to the Shinnecock Inn, Shinnecock Hills, L. I.

Seattle's Club to Have a Floral Parade.

SEATTLE, May 20.—Opening with a floral parade in the morning, there will be two days of racing at the Meadows, May 30 and 31. The parade will unquestionably be the finest that has taken place on the North Pacific Coast. The Automobile Association is working hard, and, as there are so many new cars here this spring, the interest is naturally great. There will be no trouble about the floral part of it, as all sorts of flowers, domestic and tame, are now in bloom. The receipts will be used towards building an automobile boulevard, which in time will extend around Lake Washington, a drive of 135 miles.

The Many Who Suffer for Sins of the Few.

The many answering for the sins of the few is becoming too much for law-abiding autoists, and a letter from the Runs and Tours Committee of the Long Island Automobile Club is well worth perusal and duplicating by clubs in sections where the technical trapping of autoists is being carried to an extreme. Here is what the Long Islanders say to their members:

"To the Club Members—The Board of Governors has directed this committee to exert every effort in order to protect Long Island automobilists from the unjust, if not unlawful, methods which have been followed by local constables at some points, and the prosecution of autoists on purely technical grounds. The committee is also conferring with the president and board of trustees of each incorporated village on Long Island, with a view to having the corporation limits of each village fixed and properly designated by signs.

"While the club has little sympathy for the persistent violator of speed ordinances, or the reckless driver, whose fad is to hit up a 35 to 50-mile gait on the country highways, on the contrary we know that great injustice is done to the average autoist who is a careful and moderate driver, who may innocently exceed the regulations and thus be made the victim of some local constable, or police trap.

"This committee especially urges that each member report to the chairman by letter, regarding any police traps which come under his observation. By this is meant the stationing of constables, with ropes, cables, etc., to make arrests at the extreme limit of village boundaries, where it is practically farming country.

"I trust you will co-operate regarding such conditions that come under your attention, as it is the purpose of the club to locate men at such points in order to warn automobilists and protect them against such unfair methods. Yours fraternally,

"CHAS. JEROME EDWARDS, Chairman."

Autoists who drive to the danger of other users of the road should be arrested and fined, but to set traps in out-of-the-way

places, in the outskirts of cities and towns, is a plan of procedure never intended by the framers of the law. It is doubtful, however, if the present wave of "trapping" will cease until the law has been changed in such a manner as to make impossible this form of graft, for country constables are multiplying faster than communities are beginning to realize the difference between catching violators of the rights of other users of the road and those who might happen to be traveling at a pace slightly in excess of the designated speed limits and still without inconvenience or danger to the other occupants of the highway.

The Need of Simplifying the Lubricating System.

Simplicity and reliability are so closely interrelated that even to the veriest layman the presence of a number of small parts spells complication and a liability to derangement that diminishes in proportion as the parts subject to defection decrease. Not that all apparent complication is dangerous, particularly as such an opinion regarding a device may be the result of ignorance rather than otherwise. For that matter, all complication is not apparent by any means; it is frequently hidden under a severely simple exterior, and therein lies the danger. This is true of some lubricating systems, while others stand self-revealed. When it is borne in mind that lubrication constitutes the very life of the motor, the necessity for absolute reliability in this essential becomes evident. A failure of the ignition current or of the fuel carries its own warning; in the case of a shortage of lubrication it comes too late to avert the damage.

Despite the most painstaking care that can be exercised, foreign matter occasionally finds its way into the gasoline, and the same is true of the lubricating oil. Due to its far heavier consistency, it constitutes more of an obstacle to the flow of the latter than of the former, yet it is not difficult to find cars on the market to-day, the lubricating systems of which are characterized by a maze of fine bore tubes. In sharp contrast with these are those simple systems of pump circulation which insure a constant supply of oil to all the important bearings as long as there is any in the supply tank, and this with but a fraction of the parts necessary to accomplish it. Of course, there is something to be said on each side, but it would certainly seem as if the tendency to reduce this essential to its lowest terms, thus enhancing its reliability, constituted real progress.

Interest in the Two-cycle Motor Abroad Active.

Despite the advanced state of reliability and efficiency to which the four-cycle motor has been brought on the automobile, there appears to be no question that it is not generally regarded as representing finality of design in this direction. With its more or less numerous moving parts of small size and its inherent defect of producing but one power stroke in every alternate revolution, it goes without saying that, from an engineering point of view, the four-cycle motor presents ample room for improvement—an indictment that will not be denied even by its firmest upholders. The question has been one of method rather than doubt as to the necessity for betterment. It has long been recognized that the two-cycle principle offers the foundation upon which to build in this direction, but even the least enthusiastic supporter of its rival has not been convinced that sufficient progress has been made to warrant abandonment of the four-cycle.

What is needed is investigation and experiment; if half as many builders had been devoting their attention to the evolution of the two-cycle motor as has been the case with its competitor, it is safe to say that more would be known—the problem would be better outlined to-day than is at present the case. Though great success has attended the use of large stationary units of this type on the Continent, it has justly been considered a particularly sterile field for the two-cycle motor where the automobile is concerned, so that the announcement that the Automobile Club of France will institute a series of trials of two-cycle motors is somewhat of a surprise.

A. M. C. M. A. TACKLES SHOW SITUATION.

Despite the great amount of show talk that has been going the rounds ever since the close of last winter's season, the American Motor Car Manufacturers' Association has maintained a discreet silence regarding its plans in this direction, so that show business was the chief thing of importance before the regular quarterly meeting held last week in Detroit. The date for next fall's event is still held in abeyance, although it is generally thought that Horse Show week (November 16-23), which brings a representative gathering to New York, will be decided upon. As was the case last year, the show will be held in conjunction with the Automobile Club of America, and several makers who are not members of the association, but who will exhibit at the Grand Central Palace next fall, were invited to attend the meeting to discuss matters.

It is a matter of common knowledge that the old Grand Central Palace is soon to go down before the march of improvement in that section, so that the question of housing a show for 1908 was also taken up and an important proposal offered in connection therewith. This involves the erection of a show building further uptown—in Harlem, to be as definite as possible—and one that will be half again as large as the Garden. The American Motor Car Manufacturers' Association would have control over the building so far as automobile shows were concerned, and it is given as the opinion of the promoters of the scheme that such a structure would prove a success purely as a show building, owing to the fact that many organizations find it impossible to exhibit in New York owing to the exclusive contracts granted by the Garden.

Reports of trade statistics from various members of the association were read at the meeting, and revealed an increase of fully 25 per cent. in the registrations this year up to date, despite the adverse weather conditions, and it is confidently anticipated that sales will show an increase of 50 per cent. over those of last year. It is calculated that there are, at present, about 125,000 cars registered in the country, the reports revealing the fact that the demand for light cars selling at figures below \$2,000 has largely increased, though the demand for heavier cars has not been affected. The increase in the demand for small cars is reflected by the fact brought out in the reports that New York's April registrations showed the Ford Motor Car Company to stand at the head of the list, with the Maxwell-Briscoe Motor Car Company second, and the Reo Motor Car Company, fourth.

Though testimony was being taken in Detroit in the suit against the Ford Motor Car Company while the meeting was in progress, Selden matters were not much discussed.

There was a record attendance at the meeting, the following concerns being represented: Thomas B. Jeffery Co., Kenosha, Wis.; Aerocar Co., Detroit; Maxwell-Briscoe Motor Co., Tarrytown, N. Y.; Motorcar Co., Detroit; Jackson Automobile Co., Jackson, Mich.; Ford Motor Co., Detroit; Premier Motor Mfg. Co., Indianapolis; Reo Motor Car Co., Lansing, Mich.; Welch Motor Car Co., Pontiac, Mich.; Austin Automobile Co., Grand Rapids, Mich.; St. Louis Car Co., St. Louis, Mo.; Rapid Motor Vehicle Co., Pontiac, Mich.; Wayne Automobile Co., Detroit; Dragon Automobile Co., Philadelphia; American Machine Mfg. Co., Detroit; National Motor Vehicle Co., Indianapolis; Mora Motor Car Co., Rochester N. Y.; Nordyke & Marmon Co., Indianapolis; Moline Automobile Co., Moline, Ill.; Mitchell Motor Car Co., Racine, Wis., and the DeLuxe Motor Car Co., Detroit.

ONLY FOUR COACHES FOR ANNUAL PARADE.

PHILADELPHIA, May 20.—President Edward Brinton Smith, of the local Four-in-Hand Club, blames the automobile for the rapid decline of his favorite sport. The annual parade of the club took place May 11. In former years upwards of a score of big tally-hos were in line, with horns blowing and whips snapping. Saturday's affair, however, was quite dismal in contrast. Just exactly four coaches put in an appearance at the Bellevue-Stratford, the starting point.

TAXIMETER CABS COMING TO NEW YORK.

Three hundred automobile taximeter cabs, especially designed for this work and constructed in the new Darracq cab factory at Suresnes, near Paris, will be in service on the streets of New York City about the end of July, declares Walter Allen, of the Motor Carriage Company. A few weeks ago G. Winthrop Sands, president of the company, sailed for Europe, and has fixed upon the Darracq as the most suitable vehicle for service in this country. The chassis is a four-cylinder 15-horsepower model with shaft drive, simplified and rendered more accessible in view of the rougher service it will have to perform. A very neat type of landaulet body will be supplied by Védrine from the special body-building works at Rouen, France. It is the intention of the exploiting company to charge something like thirty cents a mile, or one dollar and a half an hour. Almost a thousand cabs of this description will ultimately be put into service in New York. Negotiations are on foot for establishing similar services in Boston, Washington and Chicago.

NEW JERSEY'S ELEVENTH HOUR AUTO BILL.

TRENTON, N. J., May 20.—Many automobilists are unaware that in the closing hours of the Legislature a bill was put through the House just before adjournment and during the usual confusion. The Associated Automobile Clubs of New Jersey will endeavor to convince Governor Stokes that the bill should not be signed. The measure provides that all police officers, constables, or other officials who do not see to the enforcement of the automobile law may be fined a sum not to exceed \$200, or be peremptorily dismissed. Provision is made for twenty-five paid inspectors and a like number to serve without salary. The Commissioner of Motor Vehicles is given an increase of \$1,500 in salary and also provided with a chief inspector at \$1,500. Clauses regarding foreign autoists and drivers' certificates are also included, the tenor being to make the restrictions more severe. Those who have examined the measure contend that it is unconstitutional.

PENNSYLVANIA'S TWO BILLS ARE DEAD.

PITTSBURG, PA., May 20.—Owing to the unfortunate animosity of the Speaker of the Pennsylvania House of Representatives to the Senators who opposed one of his pet measures, sixty-eight Senate bills were practically killed in the House by the Speaker without any regard to their merit. Among them was the new Pennsylvania Motor Vehicle law, which granted reciprocal registration to automobilists registered in their home States. The Sproul State Highway bill, appropriating \$1,000,000 for the improvement of the Philadelphia-Pittsburg road, was another commendable measure which was killed. Both of the bills had passed second reading and would have gone through without any opposition. Everything was done to secure a third reading for these bills, but it was impossible. Paul C. Wolff, secretary of the Pennsylvania Motor Federation, which is the State organization of the A. A. A., was unceasing in his efforts to get the measures passed.

SEC. BRITTON TAKES UP MISSOURI STATE WORK.

ST. LOUIS, Mo., May 19.—Roy F. Britton, the veteran secretary of the St. Louis Automobile Club, has retired from that office, his new duties as secretary of the Missouri State Automobile Association requiring his entire time. He is succeeded by Samuel D. Capen, who was chosen at the recent annual meeting of the club as secretary and treasurer. All the other officers of the club were reelected: President, Alexander Euston; vice-president, Dr. E. M. Senseney; board of governors, Roy F. Britton, Alexander Euston, A. B. Lambert, H. S. Priest, Dr. E. M. Senseney, and G. M. Wright. Secretary Capen, D. R. Calhoun, and J. A. Seddon were elected on the board to fill vacancies. The treasurer's report showed a comfortable balance in the club treasury.

STORY OF AN INDUSTRIAL ACHIEVEMENT.

From a start on a capital of \$3,000, representing the savings from a soldier's pay, to the head of a corporation capitalized at \$22,500,000 in less than 30 years, sounds far more like a fairy-tale than a record of actual fact. It briefly sums up in large measure the history of the bicycle and the automobile in this country as influenced by the career of Colonel Albert A. Pope, which is set

COL. ALBERT A. POPE.

forth in a very attractive volume entitled "An Industrial Achievement." Like most of the vast manufacturing interests for which this country is noted, the Pope business began in a very modest way. The start was made immediately after the Civil War at 87 Summer street, Boston, in a single room, up three flights of stairs. It was not until 1876 that the Pope Manufacturing Company came into existence, and its attention was then devoted to the handling of small patented devices, among which the most prominent was an air-pistol. In

its desire to expand the company took up the bicycle, and it is interesting to note that the first machine built by Colonel Pope and his English friend, John Harrington, cost \$313.

At the very outset of its manufacturing career the company found that the patent situation was controlled by others; Richardson & McKee, of Boston, held one of those rare basic patents which make manufacturing without a license impossible, and excessive royalties threatened to end the existence of the business. In the final acquisition of this patent was laid the Pope policy, which has ever since been adhered to—that of fostering industry by issuing licenses to all reputable concerns who chose to engage in the same line, a right to manufacture even being granted to Cunningham, Heath & Co., old rivals of the Pope interests, and who, had they seen fit to take advantage of an offer of the patent when first presented to them, might have ended the latter's career. Not long after the acquisition of this first basic patent, the Pope company was assailed on all hands by people claiming to own patents essential to the manufacturing industry at that day and numerous actions were brought. Here again great foresight was shown by obtaining control of all patents that had a bearing on the bicycle industry. The judgment of the company in acquiring control of such patents was manifest in the fact that the litigation was always decided in its favor, while the wise policy followed on the whole patent question was strongly emphasized by the fact that after the expiration of a number of these patents, the price of the articles manufactured under them actually rose instead of falling off, as is usually the case.

But the growth and development of the Pope interests is a long story, only to be adequately told in a volume such as the one under review. The Pope Manufacturing Company increased its original capitalization of \$100,000 to \$1,000,000 within a few years. Its history since then has been one of upward leaps and bounds, but not like that of many another, merely the recital of increasing facilities to take care of increasing demands. It is far more than that, for the demand itself had to be created in the early days, and in doing so Colonel Pope benefited the country as a whole far more than he did his own company. The combination of such policies with that of judicious and widespread publicity has made the Pope name a byword the world over. The lead it assumed in the bicycle business made it thoroughly fitted to assume the same rôle in the case of the automobile, in which field its achievements are a matter of common knowledge. This unique publication is an 88-page quarto volume, executed by the Bartlett-Orr Press in a style that fits it to grace any library shelf.

ELEVEN HUNDRED MILES IN THE RAIN.

An eleven-hundred-mile automobile tour over a thousand kinds of roads, but during one continual kind of weather in the form of a spring rainstorm, was made last week by S. D. Waldon, sales manager of the Packard Motor Car Company in a 1908 Packard "30." The trip was a hastily conceived testing tour to try out the qualities of one of the four experimental Packards of the new model, and starting with a New York to Boston run, was continued back to New York by another road, and thence to Philadelphia and Pittsburg.

From New York, the run was made to Boston via New Haven and Hartford, the time from Hartford to Boston being 3 hours 35 minutes. After a rain-soaked day of demonstrating about the Hub, a party, including Alvan T. Fuller, of Boston, was made up for the return to the metropolis by the shore route through Providence. There was not an inch of dry road or a liter of dry weather as the car swept at a furious gait along the stone roads, blown by the Atlantic winds. Most of the way the going was firm, smooth and fast, but in sections the way was disputed by miles of loose boulders and ridges of native rock.

The next day, after luncheon in New York, a quick afternoon run down the famous New York-Philadelphia road was made, the highest speed reached on the good stretches being 68 miles an hour by the speedometer. That evening preparations were made for the mountain-climbing, valley-spanning chase to Pitts-

S. D. WALDON, WITH 1908 PACKARD "30," A VETERAN TRYER-OUT.

burg. The party for this last stage of the trip included Mr. Waldon, Mr. Fuller, Mr. Godshalk, of Philadelphia, and the latter's unknown friend, "Bill." Acting upon the counsel of Philadelphians who previously had made excursions into the fastnesses of Pennsylvania's tortuous mountain highways, a 5 o'clock start was made in the morning. The road taken was that leading through Columbia over the historical battlefield of Gettysburg and to Chambersburg, and thence directly across the many ridges of Allegheny mountains that corrugate the surface of Pennsylvania into rocky roads which sink to sea level only to rise successively to heights above the clouds. The storm had so deluged the countryside that hardy mountaineers of southern Pennsylvania, who had noted the characteristics of travel in all its many conditions, warned the tourists against proceeding, and predicted their failure to make the goal. All the time there was rain, and every mile was a rocky mile.

Incidents were frequent, but there were no accidents, and the progress, while rough and dangerous, was steady and sure. Three hundred and twelve miles to Greensburg were covered that day, and then a bursted tire caused a delay which brought on the growing blackness of night, and the trip was stopped until the next morning, when the run into the steel city was completed. While this ended one tour, it was only the beginning of the work that the car is now undergoing.

A RAMBLER'S 222-HOUR NON-STOP RECORD.

MINNEAPOLIS, MINN., May 20.—After running 222 hours, from 3 o'clock on the afternoon of May 10 to 9 o'clock Sunday night, May 19, and establishing a new record for a two-cylinder engine, the Model 21 Rambler, which was put under test by the Fawkes Automobile Company of Minneapolis and St. Paul, was brought to a stop at the Minneapolis garage before an interested crowd of spectators. The engine was apparently in excellent shape when it was brought to a stop Sunday night, after running over nine days continuously.

The performance of the Rambler was exceptional in the way of non-stop tests. It was on the road almost all of the time that the engine was running during the nine days, being driven through the night, in all kinds of weather. Only a small portion of the running was done under cover. Erne Simpson and Jesse Jennings were the drivers.

Severe snow storms, rain and sleet were encountered on several days. On the fifth day Jennings drove the car through a snow and sleet storm in the early morning, which forced him to stop twice to find his way. The engine suffered little, except that once or twice water collected on one of the spark plugs, and it was necessary to drain out water which had worked into the

THE THOMAS HIGH-POWERED RUNABOUT.

THOMAS PRESENTS POWERFUL RUNABOUT.

The new high-powered runabout by the E. R. Thomas Motor Company, of Buffalo, embodies the main features of design of that firm's touring cars, the differences being a special engine of high horsepower, set further back, the use of smaller wheels, a new design of frame and general fixture of pedals and levers.

The motor is of the four-cylinder water-cooled type, having five bearing crankshaft, the rear bearing being lubricated by a chain oiler. Lubrication of the motor is by a positive action pump with six sight feeds located in the dash. Four of the feeds lead to the cylinders, one to the shaft-driven fan and one to the crankcase. This oiler is operated by a shaft running from the rear end of the intake camshaft.

MARMON METHOD OF CRATING AUTOMOBILES.

As will be seen from illustration, the only criticism which might be brought against the manner in which Nordyke and Marmon crate automobiles, is that the work is too thoroughly done. The box is made to fit the car on sides and top, with just a little clearance at the ends. It is built up in sections with bottom spiked to two 4 by 6-inch skids, set in far enough to receive the weight of the car. The box is lined with tarred paper and is practically airtight and moisture-proof. The machine is so placed in the box that there is no side motion; a chock block is placed forward and back of each wheel; the axles are blocked up so that the weight is removed from the tires, and blocks are placed between the elliptic springs. Lamps, etc., are left attached to the car; spare parts are boxed, and extra tires, top, trunk rack, etc., are secured to the floor under the car.

RAMBLER NON-STOP CAR ENCOUNTERS SNOWSTORM, MAY 15.

Photo near Loring Park, Minneapolis. In the car are Erne Simpson at wheel; Jesse Jennings, assistant; E. G. Terwilleger, chief observer; L. H. Fawkes, proprietor Fawkes Auto Co., Minneapolis and St. Paul,

engine. A pounding in the cylinders became noticeable on the sixth day, giving evidence of carbon forming, but this disappeared when kerosene had been fed in through the carbureter. The engine continued to run smoothly, and oil used in unsparing quantities eased off every bearing and joint.

The engine consumed on an average of from 22 to 23 gallons of gasoline in the twenty-four hours. About ten round trips between the two cities were made each day, and in addition to this the work on city streets adds considerably to the mileage.

The car was under the eye of about fifteen observers, E. G. Terwilleger, president of the Reliance Elevator Company, and F. J. Kerner, manager of the Hartford Rubber branch, being among the chief observers. Storage batteries were changed twice, the connection being changed over to dry cells while the change was being made. No difficulty was experienced in making these changes.

GATES MILLS HILL CLIMB JUNE 8.

CLEVELAND, O., May 21.—Saturday, June 8, has been fixed as the date for the third annual hill climb of the Cleveland Automobile Club on Gates Mills Hill. Nineteen events are provided for, the entry fee per car being \$10, which must be sent in not later than June 3. The F. B. Stearns Company, of Cleveland, has challenged all comers for the record of the hill.

HOW THE MARMONS ARE SECURELY CRATED.

Car Company, Toledo, O., succeeding H. S. Leyman, resigned.

R. D. Aldrich has been appointed general sales manager of the Atwood Manufacturing Company, Amesbury, Mass. Mr. Aldrich was formerly connected with the Twentieth Century Company.

George E. Edmunds, of Edmunds & Jones Manufacturing Company, Detroit, Mich., has just returned from a two months trip to the Pacific Coast. Mr. Edmunds states he found trade conditions excellent and promising.

Harry Leyman, formerly assistant manager of the Pope Motor Car Company, Toledo, O., has been appointed sales manager of the DeLuxe Motor Car Company, of Detroit. Mr. Leyman entered upon his new duties the latter part of last week.

Robert M. Beck, long connected with the Pope Manufacturing Company as chief engineer, has gone to Hagerstown, Md., where the Pope-Fribune is manufactured, and also the Pope bicycles, the sale of which is greater than for several years.

P. L. Hussey has resigned from the Cambria Forge Company, Johnstown, Pa., and at present is located at 1115 St. Clair avenue, Cleveland. Mr. Hussey is one of the best known men in the industry, and after taking a short rest will likely connect himself with the trade again.

C. S. Carris, who with L. L. Whitman has twice broken the transcontinental record in a Franklin car, has just returned to Syracuse after completing a trip of upwards of 10,000 miles in a 1907 Franklin six-cylinder car. On this trip Mr. Carris has visited nearly all of the principal cities east of Chicago.

Owing to the promotion of H. E. Field to the position of sales manager of the Hartford Rubber Works Company, the position of branch manager at Detroit was left vacant, and C. W. Hatch, formerly with the Diamond Chain and Manufacturing Company, has been appointed to the position of local manager in that city.

C. C. Goodrich, general superintendent of the B. F. Goodrich Company, Akron, O., has announced that he will retire from the company about the first of next year and will remove East, probably to Orange, N. J. He has no plans for the future, but it is understood he will retire from active business. The death of his mother, the widow of the late Dr. B. F. Goodrich, founder of the rubber industry of Akron, through which Mr. Goodrich comes into a fortune of a million or more, is the cause of his severance from the company. His resignation follows that of J. F. Kelley from the same company, he, like Mr. Kelley, to enjoy their fortunes rather than keep closely confined to business.

NEW TRADE PUBLICATIONS.

A neat folder has just been issued by the Peerless Motor Car Company, with eight finely engraved plates of Model 15, 45-horsepower, and Model 16, 30-horsepower, 1907 Peerless cars. These represent the eight principal types of modern automobiles, the four and seven-passenger touring car, the racy roadster, limousine, coupé, cape-top roadster, berline and demi-limousine and hansom.

A catalogue is just off the press dealing with Hill precision oilers for automobiles, motor boats and other machin-

ery. Half-tones of the complete oilers and sectional line drawings of the mechanism are features of the booklet. Hill precision oilers are manufactured by the Precision Appliance Company, 832-840 Austin avenue, Chicago.

A very complete catalogue of more than ordinary elegance and care in get up has been sent forth by the Stewart & Clark Manufacturing Company, of Chicago, descriptive of the 1908 model of the Stewart speedometer. Numerous half-tones illustrate the complete indicator and its various component parts. A copy of the booklet will be forwarded to any address upon request.

Charles E. Miller, 97-101 Reade street, New York, has produced his 1907 catalogue of parts, fittings and sundries for automobiles, motor boats and motorcycles. As usual it is a voluminous affair of more than 200 pages, comprising every known article in the automobile industry. An edition of sixty thousand has been printed, and a copy can be obtained free on request by any automobilist.

INFORMATION FOR AUTO USERS

Hopewell Tire Case.—This case is a continuous casing wrapping round the tire to protect it from water, dust and grease. The case is made of the highest grades of both enameled drill and artificial leather, fastened at one end with a

THE HOPEWELL TIRE CASE.

metallic cable and at the other with a cord, which are tightened and fastened, as shown in illustration. The metallic cable is covered by a braid and treated with a moisture-proof compound. Inasmuch as the inner diameter of the tire case does not have to pass over the outside diameter of the tire, the inner portion of the tire case is made a perfect fit and has not the customary wrinkled appearance. Hopewell Brothers, 42 Osborne street, Cambridge, Mass., are the manufacturers of the tire cases.

The Latest Winchester.—A speedometer with the high-speed-record-hand is the latest product of the Winchester Speedometer Company, 1557 Broadway, New York. The auxiliary, or maximum hand, red in color, is carried by the regular indicating hand to the highest speed attained by the car and remains there when the car slows down or stops. A touch of the resetting button, which, incidentally, is

within easy reach of the chauffeur's foot, releases the maximum hand, which instantly falls back to the speed the car is then making and remains there when the car stops. The advantage to the autoist who has been summoned by the constable to stop is obvious. There is no advance in the price of the new models incorporating this device.

The Little Wonder Vulcanizer.—Louis E. Rice, Cedar Falls, Ia., is the patentee and manufacturer of a handy portable vulcanizer which it is claimed is the only one in existence, apart from factory plants, having detachable plates which will vulcanize tires on or off the rim

RICE'S LITTLE WONDER VULCANIZER.

and leave the tire the proper shape after the repair is made. The Little Wonder Vulcanizer weighs only 3 1-2 pounds and occupies so little room that it is very easily carried on any automobile. By its use the repair of a bad cut on an outer case or an inner tube can be made in about thirty minutes.

Electric Auto Lamp.—An ingenious electrical device has been placed on the market by the Royal Battery Company, of New York, consisting of a novel form of an electric lamp and an attachment which fits the gas pipes of the standard headlights and gas lamps having a 3/8-inch pipe. A number of filaments burn in a parallel simultaneously, each filament giving about four candle-power on six volts. If one filament should burn out or break, three would be left to give service. The socket or attachment also presents a new feature. It has a set screw at the upper part which tightens the bulb and makes unscrewing, owing to vibration, an impossibility. The lamp itself is fed from the ignition storage battery or dynamo. Specially treated filaments are used, and it is claimed that the lamp will last for 250 to 300 hours before it will burn out. No tools other than a screwdriver are needed for installing the apparatus; two lamps can be put in position in three minutes. A further advantage of the system is that the attachment is interchangeable with the gas system. The National Sales Corporation of 296 Broadway, New York, is selling agent for the apparatus.

ROYAL MULTIPLEX LAMP.

THE AUTOMOBILE

Through the Picturesque Country of the Four By A. G. Batchelder

WE covered the strikingly scenic sections of the big A. A. A. tour under the most unfavorable conditions that could exist. In July the mountain roads will have improved to a marked degree. Rain had preceded our coming and the heavens still had some left. Chains were a requisite and the low-hung top shut out miles of picturesque country.

But the quintette in the Pierce "Pathfinder" thoroughly enjoyed the journey over the rugged mountains of Pennsylvania and keenly admired the less strenuous climbs of the green hills of Maryland. Despite the cussed waterbars that punctuate the way, and the wet that added a source of unnecessary discomfort, we five unanimously voted that the Pittsburg-Bedford and Bedford-Baltimore runs will prove to be the best remembered and appreciated sections of the event for the Glidden and Hower trophies.

Naming the occupants of the sturdy car that carried us so resolutely and uncomplainingly, I am inclined to place the pilot first in the list, for if "Teddy" Dey had not handled that "Big Six" with such consummate and untiring skill there would have been no opportunity for Touring Board Committeeman "Phil" Flinn to assist Secretary Dai H. Lewis in preparing the details of the route, nor would Spooner have had the chance of photographing incessantly from dawn until dusk. It's a job to sit at the wheel of that road locomotive during the sunlight hours of a day, especially when the way winds up to the clouds and down again, abruptly swings around unexpected turns, includes slimy, treacherous surfaces, and now and then demands consideration quickly for other users of the highway.

There'll be some tired drivers at the conclusion of that 100-mile trip from the dirty, soot-laden haze of Pittsburg to the emerald-carpeted and shady dell at Bedford. But the task will bring a scenic recompense of surpassing beauty, sublime and inspiring, and none will regret that climb of the Alleghenies, though sweet and well-earned will be the rest over Sunday at inviting Bedford, a resort with a history that traces back fifty years.

Because the "Pathfinder" had found roads in Ohio that did not deserve even the slightest designation as such—and Committeeman Flinn will have to try again for an itinerary between Canton and Pittsburg—the big car did not report at the Hotel Schenley on Tuesday night. I was one of Arthur Banker's party that started out Wednesday morning to meet and escort the delinquent into the city. Just before we reached the Ohio line we learned, much to our chagrin, that the sought-for had eluded us by taking an unexpected route into town. Next day the energetic Banker, in company with Paul C. Wolff, secretary of the Pennsylvania Motor Federation; S. C. Garver, and "Tom" Dunn and "Bob" McCurdy, two of the Banker star demonstrators, guided us out of the smoky atmosphere to the city's limits, through Wilkinsburg, then down the serpentine hill into Turtle Creek, home of Westinghouse, and bade us godspeed at East McKeesport.

Rain was now falling, but chains had been put on and the top raised, and, hopefully, we started for the mountains and beyond. Stewartsville, Circlesville and various other villes fell to the rear, one after another, as the mechanical brute ploughed its way over and through the mushy roads. A mile of brick pavement in Irwin seemed a treat, and again in Greensburg we had a similar delight. Beyond Youngstown we struck the Loyalhanna creek

JUST BEFORE THE ESCORT LEFT US AT MCKEESPORT.

and followed its banks and the Chestnut Ridge for several miles. Beyond Ligonier we began the climb of the Laurel Ridge, rocky and likely to give the passengers of a tonneau some exercise. On the summit the going was better and in the descent the road improved considerably.

At Stoyestown Station we were at the west foot of the Allegheny mountains, and there started a ten-mile dig to the summit. At the base the trees were rich with foliage, but as we progressed skyward the green took on a lighter shade, and, intermingled with the lasting evergreens, it gradually presented a more delicate appearance until by the time the summit was reached it had disappeared entirely and the trees stood out gaunt and unadorned. Even the early dogwood had succumbed to the tardiness of Spring. A dense fog had settled down upon the mountain tops and we poked along slowly and cautiously, not knowing at what moment something might emerge from the pall that shut out the grand view that will be visible in July. Of course, the waterbars were in evidence—repeatedly crossing the road and repeatedly making one cuss the man who was responsible for their placing. Occasionally we caught glimpses of old stone and log houses, most of them uninhabited and more or less in ruins. Frequently we met lumber wagons, usually drawn by three teams of horses, and occasionally attached to traction engines.

Whenever the horses betrayed trepidation at the appearance of the unusual occupant of the road, "Phil," the horse tamer, tackled the task of subduing the fractious equines. His sonorous voice was as efficacious as Mrs. Winslow's soothing syrup is supposed to be for youngsters. Only once was the kindly aid of Mr. Flinn unrewarded, and that happened the next day and it carries a story with it, one that even now exasperates us.

From the summit to Shellsburg it was a nine-mile slide down the mountainside, with a series of ridges interrupting. First came Wolfsburg, and a couple of miles farther on was Bedford,

BESIDE THE RAYSTOWN BRANCH OF THE JUNIATA RIVER.

THEN WE PLUNGED TOWARD THE ALLEGHENIES, DESPITE RAIN.

where we put up at the Grand Central for the night. The Bedford Springs Hotel, two miles out of the city, had not been opened for the season, much to our subsequent regret.

Early the following morning we were again ready for the fray, though the overcast sky with its heavy rain clouds was not conducive to exuberant spirits. An inspection was made of the Springs hotel, its manager interviewed, and the place was O.K.'d as being a satisfactory stop for over Sunday.

On our way, we were soon in the valley of the Raystown branch of the Juniata, which with the sun lending its light and warmth will present as pretty a panorama of scenery as one could ask for. Fifteen miles had been traveled before we started the climb up Ray's Hill, which was much easier than the ascent and descent of Sideling Hill. Next came a ridge without a name, and then we negotiated Scrub Ridge, and three miles from its base ran into McConnellsburg. Soon after leaving McConnellsburg came a four-mile effort to the summit of Tuscarora Mountain. It was a road that alternated between bad and good, but possessed of those instruments of automobile torture known as waterbars. Still it seemed much easier in descending the three and a half miles, and gradually the pike improved in quality, and life was once more worth living, despite the beginning of the toll-gates, as we sped onward through Mercersburg, Greencastle and across the State line into Maryland, and were soon in bustling Hagerstown. Here we ran across Harold L. Pope, seated at the wheel of a Pope-Tribune, who was leaving in the evening for his new post at Toledo.

A Crawford demonstrator gladly guided us out of town. At Boonsboro, near which the battle of Antietam was fought, we started the crossing of the Blue Ridge. Less trying than the Alleghenies, the ridge supplied view after view of scenic beauty and possessed a roadbed superior to what had been traveled over in Pennsylvania. At Boliver we found ourselves on the other side

BEDFORD SPRINGS WILL SUPPLY A GOOD RESTING PLACE.

ON THE SUMMIT OF THE ALLEGHENIES, WE FOUND THE TREES STILL GAUNT AND BARE.

of the ridge, but we were still considerably above sea level, and from Braddock Heights, five miles before reaching Frederick, a sight of four States was possible. The "clustered spires of Frederick" were visible, and even the mountains of Virginia were to be seen far in the distance.

It was not far from Frederick that "Phil, the Horse Tamer," met with his single reverse in the way of appreciated courtesy. Noting the apprehension of a single rig that was approaching, "Engineer Teddy" hushed the noise of the big car and allowed it to coast down hill silently. The "Horse Tamer," who had sprinted ahead, took the bridle of the excited horse and led him past the car, despite the ungenerous comments of its owner. It is true that we exchanged compliments of a somewhat emphatic sort, and the parting shout of the stranger had something to say about "'tendin' to our case." As we drew into Frederick and stopped in front of the City Hotel, seeking information as to a gasoline replenishing place, a deputy sheriff and then the sheriff himself interviewed us in regard to the incident some eight miles back on the road. At first there seemed to be an inclination to cause us to await the coming of the horseman who had in mind the swearing out of a warrant for our arrest on the ground that we had caused some fancied damage to his rig. A plain statement of the case as it actually existed, a telephone conversation between the sheriff and the alleged plaintiff, and we were released from the alleged custody which was supposed to exist but which we declined to recognize except as a matter of courtesy. As a clincher, Spooner had taken a photograph as the horse was being led by in charge of our "Tamer." It was the single incident of unfriendliness that had been encountered on the way from Pittsburg.

For those who may have in mind the seeking of the house from the attic window of which Barbara Frietchie waved her country's flag, it should be here stated that the domicile is no longer in existence, though Dame Barbara's grave can be found in the cemetery, wherein Francis Barton Key, composer of the "Star-Spangled Banner," was also laid to rest. Frederick also gains celebrity through

being the birthplace of Admiral W. S. Schley.

The Frederick-Baltimore Pike is a pretty fair sort of road, and while one continues to cuss the waterbars, they are less troublesome than in Pennsylvania. A few miles from Frederick you cross the Monocacy river by the Old Jug bridge, built in 1808. Though we could have made Baltimore, we stopped for the night at Ridgeville and found good country accommodation at the Eagle Hotel. Our reason for lingering 31 miles from Baltimore was for the purpose of entering that city by daylight and being sure of the best route. Mr. Clark met us at Ellicott City, which is picturesquely located on the Patapsco river, and we were soon in front of the new Belvidere Hotel, where the tourists will stop on the night of July 22.

From Pittsburg to Baltimore exists the real picturesque and scenic part of the coming A. A. A. tour, and while the route is far from easy sledding, and will try the reliability of cars and the skill of drivers, there will be a welcome relief from the level roads of Ohio, Indiana and Illinois, a change from the monotonous succession of busy cities and sleepy villages—in fact, it will take one close to Nature, who exhibits her moods in variable forms in the miles that intervene between grimy Pittsburg and cleancut Baltimore. There is little in this world worth having unless it is fought for, and it must be admitted that there will be work for cars and drivers, but work that is within the capacity of both and well worth the scenic rewards that will be forthcoming. Springs and brakes and tires will be severely tried, and before leaving Pittsburg the wise participant will have reckoned with these items and be prepared for what will follow.

PIERCE PATHFINDER'S WORK IS DONE.

The Pierce "Pathfinder" reached New York City, Monday night, shortly after 6 o'clock, and Secretary D. H. Lewis had completed the mapping of the 1,500-mile tour, with the exception of a stretch between Canton and Pittsburg. The route covered between these two cities was found impossible for recommenda-

MANY TIMES PATHFINDER STOPPED TO HAVE HORSES LED PAST ITS SILENT CYLINDERS.

FREQUENTLY WE FOUND ROAD REPAIRERS AT SPRING WORK

tion, and Philip S. Flinn, the Pittsburg member of the Touring Board, will prepare another itinerary.

The tour will start from Cleveland, July 11, the first day's run being to Toledo, 121 miles; second day, Toledo to South Bend, 166 miles; third day, South Bend to Chicago, 101 miles. The tourists will rest in Chicago from Saturday night to Tuesday morning. South Bend will be reached on Tuesday night; Wednesday will be a run of 148 miles to Indianapolis; Thursday the route calls for 174 miles to Columbus; Friday will be occupied in reaching Pittsburg, and the following night the tourists will stop at Bedford Springs for over Sunday. Monday, July 22, will come the long run of 140 miles to Baltimore; from this city to Philadelphia, the century of Tuesday, will not be very difficult, and the final day's run from Philadelphia to New York should not be particularly trying for the survivors.

Chairman F. B. Hower, who met the party of "Pathfinders," expresses himself as confident of the great success of the tour, for which he anticipates an entry list of a hundred or more for the two trophies.

N. J. COMMISSIONER TO INVESTIGATE RUN.

TRENTON, N. J., May 27.—J. B. R. Smith, Commissioner of Motor Vehicles of New Jersey, has taken prompt action in the case of the automobile smash-up which occurred near this city last Saturday night, when four men were seriously hurt as a result of speeding their car on an alleged record run from New York to Philadelphia. The Commissioner says that if he finds it to be correct that the men were employed by the New York branch of the Packard company to race the car through New Jersey, he will proceed against the company for violation of a State law, expecting at least to revoke its license in this State.

MEETING OF A. A. A. EXECUTIVE COMMITTEE.

The monthly meeting of the A. A. A. Executive Committee was held Tuesday afternoon at the Association offices, 437 Fifth avenue, New York City. President William H. Hotchkiss

PICTURESQUE SPOTS EXIST ALONG BALTIMORE-FREDERICK PIKE.

presided, others present being First Vice-President L. R. Speare, William K. Vanderbilt, Jr., George E. Farrington, Jefferson DeMont Thompson, A. G. Batchelder and Secretary F. H. Elliott. Chairmen Charles Thaddeus Terry of the Legislative Board, Frank B. Hower of the Touring Board, Robert P. Hooper of the Good Roads Board, and Mr. Thompson of the Racing Board all presented reports indicating the present substantial activities of the national organization. The Automobile Club of Washington was admitted to membership as a State association, its territory to include the District of Columbia.

C. R. MABLEY TO MANAGE IMPORTERS' SHOW.

Carlton R. Mabley has been selected as general manager of the Importers' Automobile Salon, and will take charge of the show of foreign machines in Madison Square Garden at the end of the year. The announcement was made at a dinner given to Mr. Mabley at the Café Martin by members of the New York Automobile Trade Association.

Among those present were: Paul Lacroix (Renault), Carl Page (White), Frank Eveland (Stevens-Duryea), E. R. Hollander (Fiat), E. S. Partridge (C. G. V.), A. J. Pickard (Stearns), Alfred Reeves (A. M. C. M. A.), J. S. Josephs (Rochet-Schneider), John F. Plummer (Locomobile), S. B. Bowman (Clément-Bayard), W. M. Harradon, Peter Fogarty, W. P. Kennedy, A. G. Hamilton, A. F. Camacho, L. P. McNamara, J. A. Coch, G. A. Hewitt, and C. Andrade.

In the course of the evening it was stated that the firm of Smith & Mabley would be discontinued.

A. L. A. M. INSTITUTES MORE NEW ACTIONS.

Following up the policy of beginning actions against independent makers and dealers recently inaugurated, the Association of Licensed Automobile Manufacturers has just filed four additional suits against the Mors Motor Car Company, the Daimler Manufacturing Company, Oscar Lear Automobile Company and the York Motor Car Company.

HOW THE AUTOCAR WON THE 24-HOUR RACE

PHILADELPHIA, May 25.—Autocar, first; Frayer-Miller, second; Dragons, third and fourth; Mitchell, fifth. That was the order of finish as announced by the officials in the big 24-hour Endurance Derby, which was concluded at 4:13 P.M. This order may be changed somewhat, as the Frayer-Miller, which, secure in its position from a mileage standpoint, had been withdrawn in the last hour, when its ignition apparatus had gone wrong, was pushed under the wire at the finish by control attendants. Quick to seize the opportunity, the Dragon people filed a temporary protest with Referee Overpeck on the ground that the contest, being one of endurance and not of mileage, the Frayer-Miller should be disqualified for not having been on the track for the full twenty-four hours. The impression prevails, however, that the ruling may be based on mileage, and that the air-cooled car will retain second place.

The mileage of the five cars which finished is: Autocar, 791; Frayer-Miller, 736; Dragon, 733; Dragon, 686; Mitchell.

Another incident of the finish which might have resulted awkwardly for the winner but for the thoughtfulness of a local newspaper man, was the withdrawal of the Autocar from the track when its lead was such that in the limited time remaining it became apparent that it could not be headed. Six minutes before the time limit set for the conclusion of the race a courier from the press stand dashed into the Autocar control and warned them to get the car on the track. The result resembled an alarm at a fire station. Resting drivers jumped into their coats; attendants took a hurried look over the car, "threw 'er over," and in two minutes the Autocar was chug-chugging around the track to the plaudits of 3,500 spectators.

Ten cars lined up to take the word from Referee Overpeck. They were:

C. A. Schroeder's 40 to 60-h.p. Darracq, driven by Wm. Wallace, Jr.

W. M. Cram's 35-h.p. Mitchell, driven by H. F. Greenwalt and Edwin Yost.

H. B. Stillman's 18-h.p. Mercedes, driven by himself.

Dragon Automobile Co.'s 24-h.p. Dragon, driven by George McKay and T. F. Randolph.

The same company's 24-h.p. Dragon, driven by Edward O'Donnell and John Haynes.

The Autocar Company's 30-h.p. Autocar, driven by Joseph L. Brown and Robert Maynes.

T. M. Twining's 40-h.p. Crawford, driven by himself and R. S. Crawford.

Philadelphia Motor Car Co.'s 50-h.p. Frayer-Miller, driven by Daniel Webster and W. H. Knepper.

Ralph Mongini's 60-h.p. Matheson, driven by himself.

Girard Motor Car Co.'s 30 to 35-h.p. Cleveland, driven by George Ruhland and M. La Roche.

Starter "Joe" Keir fired his pistol at exactly 4:13 o'clock, and then started a fight for the lead between Mongini and Crawford, which put their cars several miles ahead of the others at the end of the first hour, and which saw the old automobile manufacturer gain more than a mile on his big Italian adversary, incidentally raising the hour figures for a similar event from 41 to 44 miles. Comparison is made with the figures made by the Soules brothers at Columbus, O., July 4, 1905.

The end of the second hour saw the Frayer-Miller in the lead with 84 miles, one better than the Soules record. There was nothing more doing with the records until the completion of the fifth hour, when "Dan" Webster and the Frayer-Miller, still in the lead, added a mile to Soules' 198. Again at the seventh hour the Frayer was a mile better than the Soules record of 275, and from then on to the sixteenth hour—when the leader had covered 560 miles, seven better than the record (changing the card for all the intermediate hours also), and when Webster had a 20-mile lead on the nearest car—things had a decided Frayer-Millerish aspect.

Just here, however, a dump into the backstretch ditch and resulting magneto trouble lost the Frayer nearly all its lead, and early in the eighteenth hour it was passed by the Autocar, which secured a lead of over 30 miles before the Frayer got going once more. This lead was too much to overcome, and the Autocar crew, "playing 'em safe," took no chances, although a continuance of the Frayer's misfortunes rendered such caution unnecessary and widened the margin between the cars to 55 miles at the finish.

The ditching of cars, especially on the backstretch, was quite frequent during the race, fully half a dozen spills of this character causing cars not only to lose much valuable time, but in several instances put them out of the race. The Mitchell was the first to buck the rail, just about dawn on Saturday. Then came the Frayer's mishap. The Cleveland lost second position when, shortly before midday, it carried away six sections of the backstretch rail and plumped into the ooze, later withdrawing with 544 miles to its credit. A few minutes later one of the Dragons—No. 5—burst a tire and turned a complete somersault as it penetrated the fence at the first turn beyond the grandstand.

Strange to say, none of these spills produced a serious injury. Scratches and bumps are plentiful, but the Methodist Hospital ambulance, which remained on the ground during the race, had its trouble for nothing.

The Dragon mix-up gave the public an opportunity to admire the perfect arrangements made to cope with just such accidents. The car was towed back to the Dragon quarters in a most dilapidated condition. Thirty men set to work on it at once, and in

LINE-UP OF THE TEN CARS THAT STARTED IN THE 24-HOUR RACE AT POINT BREEZE TRACK, PHILADELPHIA.

an hour and fifty minutes No. 5 was back on the job—in time to prevent the Mitchell from pre-empting fourth place.

Mongini's car, a hopeless victim of ignition troubles, was taken from the track after covering 130 miles, much to the grief of its driver, who had prepared to run the car alone through the entire race, not caring to divide the honors he was sure would be his. The Crawford suffered from the same ailment, but hung on till after daylight, having 389 miles to its credit when finally withdrawn. The smashing of a clutch roller put Stillman's five-year-old underpowered Darracq to the bad, but when it was retired it had covered 485 miles and was in fourth position.

A surprising feature of the contest was the large crowd of spectators who found time to stay all night to witness the novel scenes in the various camps and on the track.

THE 30-H.P. AUTOCAR WHICH WON THE 24-HOUR.

The following table shows the leading car at the end of each hour, with the number of miles to its credit:

Hour	Leader	Miles	Hour	Leader	Miles
1	Crawford	44	13	Frayer-Miller	469
2	Frayer-Miller	84	14	"	498
3	"	123	15	"	529
4	"	155	16	"	550
5	"	199	17	"	579
6	"	231	18	Autocar	609
7	"	276	19	"	641
8	"	307	20	"	658
9	"	349	21	"	703
10	"	378	22	"	738
11	"	409	23	"	769
12	"	440	24	"	791

The fillers-in proved to be a farce. The curtain-raiser, a three-mile event for cars costing \$1,500 or less, brought two Model C Jacksons to the tape. The time trials for the track record were abandoned, the only possible entrants being too busily engaged tuning up for the big event to bother about them. The condition of the track after the conclusion of the twenty-four-hour race was such that the officials warned all starters that to attempt fast time on it would be a very risky undertaking. As a result, but one event was started, and in that but two cars—a Pope-Hartford and an Oldsmobile. The former won in slow time, the latter suffering a puncture.

YALE STUDENTS HOLD RACE MEETING.

NEW HAVEN, CONN., May 27.—Six events were contested at the Yale Automobile Club's second meet at Bradford Driving Park, summaries of which are as follows:

Three-mile Open, Autos.—A. Folberth (Oldsmobile), 4:25 3-5; L. C. Phipps (Stoddard-Dayton), 4:29; Walter Allen (Dietrich), 4:35.

Three-mile University, Autos.—L. C. Phipps (Stoddard-Dayton), 4:32; W. J. Morden (Berliet), 4:33 4-5; G. H. Townsend, 4:47 3-5.

Three-mile Small Car Open.—Charles S. Lee (Franklin), 4:41 4-5; R. G. Bigelow (Locomobile), 4:42 1-5; C. Bether (Franklin), 4:43 4-5.

Three-mile motorcycle races were decided as follows: Two-cylinders, E. L. Johnson, 5:13 3-5; single-cylinders, P. Cox, 4:52 3-5; university race, E. Coe, 5:33 4-5.

ENTRIES FOR 200-MILE ENDURANCE RUN.

Preparations are well advanced for the New York Motor Club 200-mile endurance run on June 6. Carl Page has consented to act as pilot and will distribute the confetti from his White steamer. Patrol service will be done by a Berliet machine supplied by the American Locomotive Company, and by William B. Hurlburt's Packard. F. J. Wagner is to act as starter, and Oliver A. Quayle, president of the New York State Association of the A. A. A., will check the cars in at Albany. Secretary Hakes, of the New York State Association, will be the Chatham checker. Others to act in this capacity are Chas. Dieges, of the Timers' Club of New York, M. C. Reeves, E. L. Ferguson, C. A. Woolson and Louis R. Smith. The interests of the tour will be looked after in Philadelphia by E. C. Johnson, of the Quaker City Motor Club; similar service will be rendered in Harrisburg by W. R. Douglass.

Among present entries for the tour are a 40-horsepower Berliet engaged by James Joyce, of the American Locomotive Company, two Dragons engaged by A. L. Kull and John Haines, a 40-horsepower Lozier by H. A. Lozier, and a 30-horsepower Franklin entered by Wyckoff, Church & Partridge. It is hoped that entries will be made as early as possible to facilitate preparations.

FURTHER ACTION ON THE PIER QUESTION.

Following out the systematic move undertaken by the American Motor Car Manufacturers' Association, through its general manager, Alfred Reeves, to overcome the opposition of certain steamship lines to the gasoline commercial vehicle, there was a meeting last week with the Local Freight Agents' Association of New York City, the New York Automobile Trade Association delegating its secretary, E. V. Stratton, to co-operate. L. B. Sanders, in charge of the new motor car department of the Fiss, Doerr & Carroll Company, also attended. The freight agents are entirely in accord with the trade associations on this point, even having gone to the extent recently of passing a resolution favoring the admission of gasoline trucks to the docks. The next step will be to bring the matter before the Trunk Line Association, and through the latter to the fire underwriters.

TRADE ASSOCIATION INCORPORATES.

At a meeting of the board of directors of the New York Automobile Trade Association in the latter's new quarters in the Motor Mart at 1931 Broadway, last week, the matter of organizing the association as a corporation under the laws of this State was taken up and completed. The Haynes Automobile Company, A. G. Southworth Company, D. P. Nichols & Co., and C. B. Rice, who handles the Baker electrics in this territory, were admitted as members. Matters of interest to the trade, such as the question of holding an automobile sale week, and the refusal of some of the steamship companies to allow gasoline trucks to run on their piers, were taken up and discussed. A proposal to establish a collection department for the benefit of the members of the association was also considered.

STEARNS TO BRING OUT A SIX-CYLINDER.

For the season of 1908 the ranks of the six-cylinder advocates are to have a new entrant in the shape of the F. B. Stearns Company, of Cleveland, O., who have decided to place a high-powered model of this type on the market for next year. No details as to its chief features are as yet forthcoming, though it is stated that a number of new ideas will be incorporated, as well as the fact that they are such as to make the six-cylinder car more popular. Owing to the press of other work at the factory the new car is not expected to be seen much before December next. The first order for a six-cylinder Stearns has already been placed, however, and calls for delivery January 1, 1908.

FEATURES OF RENAULT AND PANHARD RACERS

THE three Renault machines which will endeavor to again capture the Grand Prix of the Automobile Club of France are in all essential features similar to those of last year, the only changes being in minor details. They are, in fact, an enlargement of the 1907 models of Renault touring machines.

NEW RENAULT RACER HAS VERY FAMILIAR APPEARANCE.

Distinctive features of the racer are radiator behind the motor, tread exceptionally narrow, and absence of a differential. As to the mechanism of the racer there is nothing of an extraordinary nature or that could in any sense be considered as freakish. The placing of the radiator in the rear has numerous advantages; the motor is more accessible, the machine gains in elegance, and there is a diminution of the weight on the front axle, as the result of which there is better adherence of the driving wheels and more efficient utilization of the driving power. The relieving of the front axle gives excellent results on sharp turns. It is only with the radiator in the rear of the motor that thermo-syphon water circulation can be satisfactorily adopted. The abolition of the pump cannot be regarded otherwise than as a progress, for it simplifies the mechanism. It is interesting to note that last year's Grand Prix racers showed no signs of overheating under thermo-syphon circulation. The Renaults of the Auvergne circuit and the 1905 Vanderbilt, which were equipped with a pump, overheated enormously. The radiator, as is well-known, consists of a number of vertical tubes of small diameter with space between them for the passage of air. First adopted on the Paris-Berlin voitures, the system has now been developed to a perfect condition.

Four cylinders cast in pairs, bore 6.4 inches and stroke 5.9 inches, are announced as developing 100-horsepower; in reality the effective power is considerably in excess of this. Valve mechanism is as on the touring machines, a single camshaft operating valves all on one side. Although the Grand Prix is run with a limited allowance of fuel, the standard carbureter, with the improvements embodied in the 1907 touring machine, is employed. Ignition is by high-tension Simms-Bosch magneto with Renault mica spark plugs.

An inverted cone clutch is used on the three racing machines. The female member is cut in several places, forming a number of blades turned inwards, providing progressive friction on the male cone. Three speeds and reverse are obtained by sliding-

gear transmission, with direct drive on the high gear. The designers of the machine declare that the abolition of the differential is justified by the speed at which the car is intended to travel. At high speeds the wheels of a racing car frequently leave the ground. With a differential, when one wheel has left the road the other loses its propulsive action; thus for racing purposes the rear axle without differential is more efficient than one fitted with this organ.

Neither oil nor gasoline are under pressure on the racers. Renault liquid shock absorbers are employed, and it is very probable that Michelin dismountable rims will be used.

It is difficult to recognize the familiar Panhard in the three powerful racers produced from the Paris pioneer factory, for competition over the Dieppe circuit. Instead of a honeycomb radiator across the fore end of the chassis, this organ is now to the rear of the engine, about midway on the length of the frame. It is the position inaugurated by Renault, followed by Bayard-Clément on their cab chassis, and now taken up by Panhard. The four separate steel cylinders with copper jackets are 7.2 inches bore by 6.6 inches stroke, the largest displacement of any European machine in the race. Cylinder heads and valve pockets are of cast iron. Valves are on opposite sides, with integral cams. Ignition is by high-tension Eiseman oscillating magneto mounted in front of the engine on the forward cross member, and gear-driven off the camshaft. Spark plugs are on the sides, immediately over the inlet valves. Water circulation is assured by a centrifugal pump, the honeycomb radiator being of the type generally employed on Panhard machines. Owing to its new position a square opening has to be cut through it to allow of the passage of the steering column. A Krebs carbureter, with perpendicular currents and hydraulic regulator is employed, and is located on the right-hand side of the engine. All four exhausts are united in a common manifold, opening to the air

PANHARD MACHINE WITH MANY NEW FEATURES.

from a longitudinal pipe under the frame. Transmission and final drive show fewer changes; a Hele-Shaw multiple disk clutch as formerly; four speeds forward with reverse by separate lever, and cardan shaft to rear live axle. Krebs shock absorbers are used on all the racers; R. B. F. ball bearings are employed throughout in the transmission, and Michelin tires and dismountable rims have been adopted.

NEW YORK STATE "BLUE BOOK" ISSUE.

This week the Class Journal Company, publishers of THE AUTOMOBILE, issue the second volume of the 1907 series of the "Official Automobile A. A. A. Blue Book." This volume, which is No. 1 of the series, deals primarily with New York City and State, with a Canadian section, also with extensive routes into the Middle West. It is a book of 637 pages, illustrated with a large number of route maps, and in the neighborhood of 140 city and town maps, giving principal entrances and exits.

The accompanying map is a reduced reproduction of the New York State map in the front of the "Blue Book." In addition to New York State, it shows the principal connecting routes into New England, northern New Jersey, and upper Pennsylvania, also the Canadian route from the principal New York State waterway—Niagara Falls—to Hamilton, Toronto, Kingston, Montreal, and Quebec, with additional connections across the St. Lawrence from Thousand Island points and Ogdensburg to the route along the upper shore of Lake Ontario, connecting eastward to Montreal and Quebec, westward to Kingston, Toronto, and Hamilton.

The circles at the location of the most important cities represent centers of sections in the New York State volume listing *outbound* routes. The figures inside the circles represent the pages in the Blue Book where the title page of the different sec-

tions will be found, this map serving as a "graphic index" to the principal contents of the volume. For instance, the circle for Albany, N. Y., contains the figure "181;" turning to page 181, the tourist has the table of contents for the Albany section spread out before him. The same applies to all the other sections of the volume including the Canadian centers, Toronto, Montreal and Quebec.

For the first time the "Blue Book" has extended its compilations and map work into the West, the last seventy-five pages dealing with the principal through routes in Ohio, Indiana, and Illinois, with one route from Chicago to Milwaukee, Wis. Of course, the Western routes are fragmentary at this time, but Cleveland, Toledo, Detroit, Jackson, South Bend, Chicago, Milwaukee, Elgin-Aurora (Ill.), Indianapolis, Louisville, Cincinnati, Dayton, Springfield, Columbus, and several other important centers are connected by lines which will enable the tourist to plan his trips in that territory much better than has been possible before. All of these and numerous other cities in the Middle West have been mapped out with the same thoroughness that has characterized the work of the "Blue Book" in the East, and while the map work in the Middle West has only been begun, there are a few general maps that show the "lay of the land."

The New York State and Canadian volume, like the New England volume, sells for \$2.50 postpaid, by the Class Journal Company, Flatiron Building, New York.

MAP REPRODUCED FROM NEW YORK STATE BLUE BOOK, AND SLIGHTLY REDUCED IN SIZE.

SOME FEATURES OF AUTOMOBILE CONSTRUCTION*

By THOS. J. FAY, E.E.

THERE is still another grade of chrome nickel steel that is quite serviceable in motor car work for minor parts, an investigation of which exhibited qualities as follows:

Chrome Nickel Steel—"D."

CHEMICAL COMPOSITION						
Chromium	Nickel	Carbon	Silicon	Sulphur	Phosphorus	Manganese
0.63	2.19	0.39	0.19	0.034	0.021	0.19
to	to	to	to	to	to	to
0.71	2.09	0.36	0.24	0.039	0.026	0.16

PHYSICAL PROPERTIES—NORMAL

T. S.	E. L.	Ex.-2"	Con.-3"	Structure
110,000	90,000	16	64	} Close
to	to	to	to	
100,000	80,000	14	61	

QUENCHED AND ANNEALED

155,000	150,000	12	51	} Close
to	to	to	to	
145,000	144,000	10	56	

This product, while in no way equal to specimens "A" or "B," is distinctly superior to the product "C"; at the same time it costs no more than about one-half the price of the product "C."

- (a) The price of steel is no sign of quality.
- (b) Elastic limit and elongation in conjunction may be considered as a sign of quality if sulphur and phosphorus are low.
- (c) A marked difference between tensile strength and elongation point to "doctored" chrome nickel steel.
- (d) Good carbon steel at two cents per pound is better than bad chrome nickel steel at 20 cents per pound.

Having taken up the properties of chrome nickel steel, it may be well to say a few words about nickel steel.

Nickel steel, if free from seams and its most likely imperfections, would seem to be superior to carbon steel, provided the carbon to nickel relation is closely held; but every time the speaker has used nickel steel, a large percentage of it showed seams and cracks, and recently the speaker observed the utter failure of this product ere it could be put into the car for which it was intended; in other words, the forgings showed cracks, and on attempting "heat treatment" the cracks developed.

Nickel steel is notoriously hard to make, and while nickel steel holds good properties, it is the speaker's opinion that it is too uncertain to be advantageous for use in cars of pretensions.

Carbon steel, in spite of its well-known characteristics, will stand further investigation. Gears, for illustration, of low carbon steel below 0.10, even with high phosphorus and case-hardened, are far superior to gears of from 0.20 to 0.30 carbon acid open hearth steel, which, when case-hardened, shows a coarse crystalline structure, and the "armor" chips off like porcelain.

It would seem, then, for "cementing" case-hardening, gears must be below 0.15 carbon; that is, below the carbon that would show temper when quenched. If case-hardening is not desired, then carbon steel gears should be comparatively high in carbon, say 0.40 to 0.50 carbon, when the results would be as follows:

Carbon Steel—"E."

CHEMICAL COMPOSITION				
Carbon	Silicon	Sulphur	Phosphorus	Manganese
0.45	0.20	0.017	0.024	0.40

PHYSICAL PROPERTIES—NORMAL

to	to	to	to	
150,000	85,000	9	54	

In this we have a product costing but a small sum in comparison, yet, withal, quite as good or superior to the inferior grades of chrome nickel steel; hence it is really a question as to the advantage of paying a large sum for an inferior product or a small sum for a superior product, merely to change the name.

Of course, superior grades of chrome nickel steel are so far superior as not to be classed in any way with carbon steel, even when the carbon steel is skillfully treated, and the chrome nickel steel is employed in its normal state.

The speaker has for some time held some views about carbon steel that seemed to elude proof, mostly, perhaps, for lack of time to make curves, such as would bring out the true characteristics. It occurred to the speaker that this might be an opportune moment to air some views on this subject, and the chart Fig. 1 was constructed for the purpose. The chart in question shows several things, among which are as follows:

- (a) The theoretical tensile strength for the respective carbon values can only be attained in practice, for carbon, ranging between 0.10 and 0.40 per cent., unless by some especial attempt or in isolated instances.
- (b) The curve B shows the promised elastic limit of carbon

FIG. 1.—Chart illustrating physical properties of carbon steel.

steel,—acid open hearth—which is very much higher than the actual elastic limit, as given in curve A₁ for the carbon values.

(c) The curve B₂ of tensile strength is above the theoretical, whereas the curve A₂ of actual tensile values falls below, for all products above 0.40 per cent. carbon and for mild steel below 0.10 per cent. carbon, while in no case does the actual tensile values even reach the maximum theoretical values.

(d) The curve B₂ shows a lower elongation for the promised steel than that given in the curve A₂ of actual tests, thus showing an actual loss of value on the part of mills in their endeavor to attain a high tensile value and a corresponding elastic limit.

(e) The chart also shows very clearly that acid open hearth steel is superior to basic products, so much superior, in fact, that the minimum expectation with the acid process is the maximum expectation with the basic process.

(f) The curve A₁ shows that the elastic limit of steel, between 0.20 and 0.35 carbon, fails to increase by any well defined pro-

portional value. This is an extremely important matter, because it has been found by oft repeated attempts that gears, for illustration, ranging in carbon between 0.20 and 0.30 per cent., when case-hardened, are very frequently a flat failure,

of car, and very likely the designer figured on a much higher elastic limit of the carbon steel than the limits usually realized in practice; but before leaving this phase of the subject, it may be well to say, a design to be copied, *must include a copy of the materials as well as duplicating the dimensions*,—a Chinese copy—else the process augurs trouble for all concerned.

The question of machining chrome nickel steel is probably of greater interest than any question of details or design of parts that can be exposed at this time, and for brevity the speaker will quote the facts and let reasons stand as self-evident.

In experimenting upon this phase of the motor car question, three sizes of back-geared lathes were used, as follows: 30-inch swing, 20-inch swing, and 16-inch swing. The 30 and 20-inch swing lathes were heavy and rigid and furnished by Isaac Johnson & Son, Jr., of Philadelphia, Pa. Not believing that the smaller lathes were of any real value, they were not actually purchased, but the work was taken out to shops having them.

The relative value of the lathes was found to be as follows:

Thirty-inch lathes rated as 100.

Twenty-inch lathes proved to be 66.

Sixteen-inch lathes proved to be valueless.

The work was all regular automobile product, as crankshafts, connecting rods, and similar parts, of E. F. 60-0 Krupp chrome nickel steel, with a few exceptions, in which Bischoff special auto steel was used. The cuts taken on the 30-inch lathes are shown in Fig. 2 and Fig. 3, and here it may be well to say, forgings, when annealed, cut just as easy as "normal" product, and for the benefit of any who may now be in trouble with forgings, the speaker will be glad to extend further information about the annealing question. The time taken on the respective

FIG. 1.—Cut from chrome nickel steel taken on 30-inch lathe.

and the only reason for selecting such high carbon is to attain a higher elastic limit than that done to a lower carbon range.

If, however, the gain in elastic limit can not be counted upon, then to risk attaining a crystalline structure is without a good reason, for, as no doubt is well known, steel below 0.20 per cent. carbon may be used without any chance of developing a coarse structure in the bent treatment, referring to good steel, of course. Many failures must be due to the proportioning of parts based on the elastic limit as given in the curve B₁, whereas the curve A₁ is more nearly the true guide. To cite an example for illustration, it is but necessary to put down the figures, viz.:

0.30 CARBON STEEL

A₁ elastic limit, 29,000 lbs. per square inch.

B₁ elastic limit, 52,400 lbs. per square inch.

Any engineer who figures on over 50,000 pounds elastic limit, and realizes less than 30,000 pounds, should stay awake o' nights and worry about the feature.

But a few days ago the speaker inspected a very high-priced foreign touring car, in which the carbon shaft "twisted." The conditions may be set down about as follows:

- Rating of motor..... 40 horsepower.
- Weight of car..... About 3,600 lbs.
- Diameter of shaft..... 1 3-8 inches.
- Material of shaft..... Carbon steel.

It is not the purpose here to "knock," or the question might come up as to why any one should go to Europe to get a car with a 1 3-8-inch carbon steel cardan shaft, to hold down a 40-horsepower motor, or drive a big limousine through a sea of mud.

This was a good case of using carbon steel, exactly the size of a chrome nickel steel cardan shaft in another foreign make

FIG. 2.—Another specimen showing capacity of heavy lathe on alloy steel.

lathes was carefully tabulated for similar parts, and there is no reason to doubt the accuracy of the ratings for the experiment has been going on for several months, and each day proves more conclusively that a large rigid and well-constructed lathe is the best for the purpose. (To be concluded.)

WHAT AUTO INVENTORS ARE DOING ABROAD

It is not necessary to have traveled much by automobile to know that doors have a tendency to rattle when going over an uneven road surface, or whenever the speed is more than a dog trot. Ferdinand Charron, the well-known French automobilist, has devised a simple little appliance to remove this annoyance.

An examination of the sketch, reproduced from the French automobile journal *Omnia*, will readily explain the nature of the invention. *A* is the frame of the door, *C* is the metal plate hinged at *D* and held against the door *B* by a coil spring *E*. The pressure exerted by the plate *C* against the door is sufficient to prevent all vibration. Provision is made for regulating the tension of the spring by means of the screw *F* passing through metal plate *H* and held in position by nut *K*. Fig. 2 is a variation of the first system, the spring being replaced by a rubber ball *F*. Of course the spring or rubber ball must not be too strong to make any difficulty in closing the door.

TO CURE RATTLING DOORS.

With the spring this can be regulated to a nicety, but with the rubber no adjustments are possible. A good point of this appliance is the ease with which it can be applied to any automobile body.

A Positive Car Locking Device.

Under the title of the "Autofreund," a German manufacturer has just brought out a novel means of preventing the unauthorized tampering with that most important essential of the car, the change speed lever. It is described and illustrated as shown by the accompanying line sketch in a recent issue of *Der Motorwagen*. There is nothing radically new or novel about the idea, but in view of the fact that even the average street gamin is becoming so familiar with some things about the automobile, that it is no longer safe to leave one standing at the curb unguarded, it would seem that some such precaution as this is necessary. The lever may be placed in the neutral or other notch and the lock can be used, and when thus held fast the key must be inserted through an opening drilled through the side bars of the gateways before it can be released. Lock switches, plugs and similar devices serve a good end by preventing the starting of the car, but it would seem that such an arrangement as this would eventually come in.

PREVENTS MEDDLING WITH THE GEARS.

A Light Car of Many Features.

The somewhat unusual idea of using an independent water circulating system for each cylinder, though not entirely novel,

is presented here as but one out of the way feature of a new English "light car" called the Phoenix, described in a recent issue of *Motor* (London). It will be recalled that the Swiss racers built by the Dufaux Brothers some two or three years ago incorporated the water-cooling system directly with the cylinder. The idea in this case is somewhat different, as not alone the radiators but all their parts are practically independent, almost the same as if two single-cylinder motors were placed side by side. The circulation is on the thermo-syphon principle and

INDEPENDENT RADIATOR SYSTEM OF THE PHOENIX.

the two semi-circular radiators of vertical gilled tubes are placed on each side of the car, with the engine between them, somewhat like the barbettes of a man-of-war. This is not the only unconventional feature—bizarre would be a better characterization, as the vehicle apparently teems with things that are different. It is, in short, a sort of law unto itself. The old time idea of using a two-chain transmission—i.e., a chain drive from the motor to a planetary gear with a second chain from the latter to the rear axle, has been revived among others.

A New Triple Compression Pump.

A triplex pump which has the advantage of diminishing the labor usually attending the inflation of a big automobile tire has been produced by a French inventor. *Omnia* describes it as follows: There are three cylinders, *A*, *B* and *C*, of different diameters, the pistons of which are all operated by the same handle *Q*. The base of the pump is similar to those in general use; it is shown disconnected on the side sketch. When the handle *Q* is drawn up, the three pistons ascend together, air entering by the hole *D* of the guide *P* in cylinder *A*, passes around the piston and lodges below it. On the first down stroke the air is driven through the passage *E* into the connecting cylinder *B*. At the third movement the air compressed in *A* is compressed again by passing from cylinder *B* to *C* by the canal *H*, for the cylinder *C* is smaller than the others. The air having passed under the cylinder *C* is further compressed on the fourth stroke of the pistons. In this pump there is no lost stroke, for the operator compresses air on both the upward and downward movements.

LABOR SAVING TIRE PUMP.

SOME HINTS FOR THE OWNER-AUTOIST

BY THE MAN AT THE WHEEL.

WITH the advent of the summer touring season in full force, there will doubtless be a recurrence of the string of mishaps, many of them fatalities, that are made so much of by the daily press and in the accounts of which the "deranged steering gear" also figures so prominently. Of course, all automobile accidents of the class in question are not traceable to the steering gear by any means, any more than so many fires of unknown origin are caused by "defective insulation" of the electric-light wiring. Many a fire which the ubiquitous scribe has put down to this cause has been found to have taken place in buildings totally innocent of electric-light wiring of any kind; in the same way more than one fatal collision between an automobile and a wayside telegraph pole which has been attributed to a deranged steering gear, has, in some marvellous and unfathomable manner, left that same steering gear in perfect working order after the shock of the accident. Of course, it may be said that the shock righted it, which is not impossible by any means, but "deranged steering gear" may in numerous cases be liberally translated as "reckless speeding," frequently on an unknown road.

The moral is plain, however, for of all the highly important parts of the car, it is probably safe to say that the steering gear comes in for less attention in the way of inspection than any other which has equally vital functions to perform. It is subjected to severe shocks at all times and the wear on its working parts is considerable, but it is seldom dissected for inspection except when necessity actually demands it. No car should be put in commission for another season's running without having this properly attended to. The entire steering gear, connections and linkage should be dismantled, thoroughly cleaned, and any parts that show undue wear replaced. It should then be well oiled, the drag link packed with fresh grease and covered with pliable leather, all adjustments properly made and carefully reassembled. The opportunity should also be taken advantage of to test the front wheels to see if they track properly; this is not exactly a dangerous fault, but it is very hard on the tires and renders steering more difficult and it may lead to injury.

Give the Lubricating System a Good Overhauling.

Of course, there are always a great many things to be gone over in putting a car into commission for another season's use after it has been laid up for some time, and if it is possible to give all of them the proper attention, so much the better, but there are some that should never be overlooked on such an occasion, and it goes without saying that an overhauling of the lubricating system easily heads the list. This is more particularly the case where it is characterized by the use of a number of small bore tubes constituting the separate feeds. It is almost impossible to so place the latter that they will not have some part of their length horizontal, and any tendency of the oil to gum in the tubes or any sediment deposited will be concentrated at such points. Even though the tube be otherwise free, the film of oil that coats its interior surface when the feed stops may have hardened, thus reducing its bore considerably. These leads should be dismantled and, if possible, live steam blown through them. Where not available, plugging one end of the tube and filling it with gasoline which is allowed to stand in it some time will serve as an excellent cleanser. It should be supplemented in either case by shoving a piece of wire through the tubes to make certain that they are clear throughout their length. Similar attention should be paid the interior of the mechanical oiler and the sight feeds, while the crankcase should be drained and flushed with gasoline to clear out all traces of the old oil, the same process being applied to the cylinders, thus insuring a start at the beginning of the season with an absolutely clean lubricating system throughout. Proper attention in good season to such essentials as the steering gear and the lubricating system constitute insurance, the worth of

which is not to be underestimated. Neglect has to be paid for sooner or later, at a rate which causes many an autoist to decry the pastime owing to the heavy expense of keeping his car on the road. It is the old, old story of the stitch in time.

Know Your Own Car and Drive It, Too.

Next to knowing his own car down to the last detail, the owner-autoist who does all his own work should see that he alone does the driving, except when the wheel is turned over to a friend while he is in the car. The subject may appear somewhat outside the province of the present page, but a recent experience which is fresh in mind at the moment makes it opportune to digress a bit to consider whether an automobile is a proper subject to be loaned out at times. Whether he cares to do so or not must, of course, always be a matter for the owner himself to decide; the risk of acquiring some costly experience in this direction is what should prove the deterring factor. Speaking generally, an automobile is not a thing to be borrowed or loaned indiscriminately. No matter how good a driver an autoist may be, no one realizes the needs of a machine to quite the same extent as the man who owns it and takes care of it constantly. Some of these grandstand drivers who can make such an excellent showing before an admiring crowd are notoriously absent-minded when it comes to keeping an eye on the lubricating oil or the water. In the case referred to above as calling the subject to mind, one day's use of a light car by a would-be chauffeur resulted in a bill for repairs amounting to \$50. The engine ran very hot as a usual thing, and if kept on the low gear for any length of time boiled a great deal of water away. The usual thing happened; it is hardly necessary to go into details. Another case that resulted even more seriously grew out of the loan of a car to a friend by a city agent. The friend ran the car all day and part of the night—ran it, in fact, until it would run no longer, because the pistons had seized. In addition to losing the use of the car for a week or more while repairs were being made, the agent had the pleasure of towing it in some twenty miles from where it stranded, and the bill was not light.

An Opportunity to Economize on Lubricant.

While on the subject of the man who not only runs, but grooms his own car, it will be opportune to mention a method of effecting an economy, which, to judge from the majority of cars, is seldom taken advantage of. Of course, it is nothing one way or the other, to the paid driver, whether the lubricating oil put into the crankcase leaks out again half as fast as it is fed, or not. The "old man" pays for it, and, like as not, the driver curses the machine roundly for giving him trouble in this respect, whereas the only thing necessary to prevent this extravagant waste is a little adjustment in nine cases out of ten. It is always easy to detect a road where a number of automobiles have stood for any length of time, or where they pass constantly, even though it be smoothly paved so that no tracks would ordinarily be visible. The trail of lubricating oil that is over everything is as unmistakable a sign of the automobile as horsetracks on a country road are of the equine motor.

This is true of the older cars particularly; the adoption of the continuous engine pan on cars of later design has in most instances only effected one thing and that is to prevent the oil reaching the ground. It falls into the pan, where it is just as much wasted as if it fell by the wayside. Attention to the end bearings of the motor and gearcase and the joints of the crankcase where the oil-pan is bolted to the upper half, would do much to lessen this waste, though much of it is the direct result of an excessive supply. Remedying such a state of affairs is not alone an economy in oil, but it tends to keep things far cleaner, as a motor dripping with oil collects no end of dust and grit.

THE CHAUFFEUR VERSUS THE MOTORMAN

By GEORGE RICE

BOTH of modern creation, and each operating a machine of power and speed, the right of way is often questioned by the chauffeur and the motor car man. It is true that the motor car of the electrical street line is confined within its tracks. These lines of tracks are held as kind of sacred by many of the

motormen. But the inconsiderate chauffeur often fails to realize the importance and restriction of the same. He runs his speedy automobile over the line of tracks at will. He follows up cars to get in the suction of the same, thereby avoiding a head wind, provided that the trolley car goes fast enough to suit him. He crosses at critical points ahead of moving cars, and so on, and to counterbalance all this the motorman of the street car line does even worse things. He feels that he has the right of way between the tracks of his line along his route, and, as his car is pretty heavy and strong nowadays, he is liable to insist upon his rights with force. In fact, I have seen demonstrations of his

FIG. 1.—Where quick action is necessary.

tactics at various points along the car lines. I thought that a good way to get at the bottom of the thing would be to ride for some time on the front of some of the street cars in the congested sections, and likewise through the country, where automobiles were prone to speed.

Some of the Results of Observation.

I went further than this, and occupied a seat with a chauffeur or two, to get the other side of the question. I had not been on a car long before I observed the motorman apply the brake furiously, while he shut off the power with the other hand. While he pounded the bell, the car shot ahead, and we just barely missed smashing into an automobile which came out of a side street like a wisp-o'-the-hill. Had I been in the motorman's place I could not have done better. He worked quickly and prevented a disaster. The condition was as in diagram Fig. 1. I occupied the front platform of car 1. The car moved in the direction of the arrow. Car 2 moved the other way, and happened along just right to block the line of vision for the motorman of car 1, on the side street. Hence the automobile came out, and the juncture of the car and the machine almost happened at (A). The miss was a narrow one.

FIG. 2.—A quick turn and a collision.

Then I rode with an automobilist, and the circumstances illustrated in Fig. 2 came up. You can never tell just what a car is going to do. The modern electrical street car moves with considerable alertness in these days of improved mechanical devices. Even the big cars can make a pretty abrupt and quick turn on a curve. We were moving merrily along at good speed in our automobile, following along the line of the track. A car was speeding along in the same direction. Suddenly it turned from the main line (C) down to the cross street, making the curve sharply at (B). We hit this point at very nearly the same time. Our machine was at (D). In another second it was on the dashboard of the car. We got a very substantial bump. Both the car and the automobile came to a stop in the nick of time, otherwise there would have been some serious damage done. As it was, we got out of it with some scratches and abrasions on the machine and car, not overlooking a few on our own persons. After passing the usual compliments of the day with a varied assortment of cuss words, the conductor of the car took the event down in writing and inscribed the names and addresses of the interested witnesses, and then we passed on.

From Rear of Trolley.

Then I rode on the tail end of a trolley car, because I happened to observe a party of automobilists following it up. I had been told that it was dangerous business to follow close in the wake of a car. After the accident (for an accident happened this time) the chauffeur told me that he liked to get in the wind of a car and ride easily along without the breezes fanning his cheeks. I told him afterwards that he

FIG. 3.—Just in time to meet head-on.

ought to put up a wind guard. A wind guard is safer, better and cheaper than utilizing car property for this service. Well, the chauffeur pushed on back of us. He seemed to be very placid. I wondered why the party in the automobile did not reach forward and give the fellow a punch. But he did not. Our car, marked (F) in Fig. 3, suddenly slackened. The chauffeur was on us in his automobile (E). He saw he could not check his machine quick enough to avoid a bump, and therefore he turned off to the other track at (H). Unfortunately, a car (G) was due at that point at that time, and the car was on time. The two came together with a bang. Fortunately no one was hurt badly. But the front of the car (G) and all of the forward end of the automobile was rendered quite unfit for future use. The conventional diarying of episodes was made. Names (most of them fictitious) were taken down for future reference in the courts in the event of claims for damages, and the wrecked machines were towed home very much the worse for wear.

The Menace of the Trailing Wire.

I thought that I was done, but there was more to come. A baby cyclone had struck town, and some of the poles of the power company were broken off as shown in Fig. 4. A lineman was up on one of these poles, with a long wire trailing to the street. The upper portion of the pole had been snapped off by the wind, the pole top being supported by the many wires. The trailing wire wound up on the hub of a driving wheel and pulled the tottering pole top down more and more, with the lineman

making timely remarks. It is very unsafe to run over wires hanging from poles. They might be charged and you might get a shock. It is best to avoid them.

The final incident to which I shall refer is exemplified in Fig. 5. We were scudding along in grand order, through a congested section, when a car came out of a cross street rounding a curve

FIG. 4.—Illustrating the trailing wire and broken pole incident.

at our front. There seemed for all the world plenty of space between the fore end of this car and the side of a car which was passing on the other track. But the modern cars are long and the ends often reach far over the curve of the track when making a turn. So it happened in this case. The front of the car swung clear forward and out, and the machine got a good squeeze, as illustrated. I am inclined to believe that both chauffeurs and motormen do all they possibly can to avoid accidents. Nevertheless, in the rush for making time, the machines come into contact occasionally.

But both the modern trolley car and the automobile are heavy bodies, and the amount of energy stored up in them when they are moving even at a moderate rate of travel is only realized when they happen to strike an obstacle. Means of control are proportioned to the size and weight of the cars, but long familiarity with danger makes even the most careful of drivers, whether of automobiles or electric cars, a trifle reckless, and sooner or later they miscalculate. Of the two, it almost goes without saying that the motormen are far more careful as a class than the automobile chauffeurs. Anyone who rides on city street cars for any length of time, and carries his powers of observation with him, cannot fail to notice this at every turn. The instant response to the throttle and the absolute certainty with which the vehicle can be brought to a stop within an amazingly short space, make for a control on the automobile that is equalled by nothing else that travels on wheels. And it is in the mastery of his car in difficult situations that the driver delights. Running beside a trolley car at ten or twelve miles an hour, he spies a truck half a block ahead; a car bound in the opposite direction is coming along at full speed on the other track. Prudence would dictate a slow-down and a momentary

FIG. 5.—Caught between two street cars where one of them turns.

halt for a clear way ahead, but skill at the wheel and levers whispers "You can do it," and though the car is a long one, and there are women and children passengers in the tonneau, he whips the throttle lever down a dozen notches, a quick turn of the wrist on the steering wheel and the trick is done, with the automobile now traveling serenely in front of the trolley car and what appeared to be an impending tangle far to the rear.

THE AUTOMOBILE CALENDAR. AMERICAN.

Shows and Meetings.

- Oct. 31-Nov. 7...—New York City, Madison Square Garden, Eighth Annual Automobile Show, Association of Licensed Automobile Manufacturers.
- Nov. 30-Dec. 7...—Chicago, Coliseum and First Regt. Armory. Eighth Annual National Automobile Show and First Annual Commercial Vehicle Show, National Association of Automobile Manufacturers.
- Races, Hill-Climbs, etc.**
- June 6.....—New York City, 200-mile Endurance Run, under the auspices of the New York Motor Club.
- June 8.....—Cleveland, Third Annual Gates' Mill Hill Climb, Cleveland Automobile Club.
- June 12.....—National Orphans' Day, Instituted by the American Automobile Association.
- June 19-22.....—New York City, Sealed Bonnet Contest, under the auspices of the Automobile Club of America.
- June 20.....—Albany, N. Y., Annual Tour of the Albany Automobile Club; Route, via New York and Asbury Park, to Atlantic City.
- June 27-28.....—Chicago, Elgin-Aurora Reliability Run, Chicago Motor Club and Chicago Automobile Trade Assn.
- July 10.....—Cleveland, O., Start of Fourth Annual Tour of the American Automobile Association, for the Glidden Trophy. Finishes in New York City on or about July 23.
- July 13.....—Chicago, Race Meet for the Entertainment of the Glidden Tourists, Chicago Automobile Club.
- July 25-28.....—Providence, R. I., Annual Meet of the Federation of American Motorcyclists.
- Aug. 1.....—Algonquin, Ill., Hill Climb, Chicago Motor Club and Chicago Automobile Trade Association.
- Sept. 5.....—Chicago, Cedar Lake Economy Run, Chicago Motor Club and Chicago Automobile Trade Assn.
- Sept. 14.....—Albany, N. Y., 95-mile Road Race, under the auspices of the Albany Automobile Club.
- Oct. 19.....—St. Louis, Mo., International Aerial Race of the Gordon Bennett Prize. Aero Club of America.

Motor Boat Races.

- June 8.....—670-Mile Ocean Motor Boat Race, New York to Bermuda. Motor Boat Club of America and Royal Bermuda Yacht Club.
- June 15-28.....—Kiel (Germany) Motor Boat Races.
- July 20.....—New York to Marblehead, Mass., 270-mile Motor Boat Race. New Rochelle Yacht Club.
- August 22.....—New York to Jamestown (Va.), Annual Cruise American Power Boat Association.
- Sept. 2-6.....—Jamestown (Va.) Exposition, Motor Boat Races.

FOREIGN.

Shows.

- June 25-30.....—St. Petersburg, Russia, Automobile Show.
- Nov. 12-Dec. 1...—Paris, Exposition Decennale de l'Automobile. Grand Palais, Esplanade des Invalides, Automobile Club of France.

Races, Hill-Climbs, etc.

- June 3-12.....—Paris, Electric Vehicle Competition, Automobile Club of France.
- June 3-12.....—Herkomer Cup, Automobile Club of Bavaria.
- June 10.....—Pekin-Paris Automobile Tour, Start from Pekin, Inaugurated by "Le Matin."
- June 14.....—German Emperor's Cup, Taunus Circuit, Imperial Automobile Club.
- June 20-22.....—American Gold Cup, Start from New York of European Tour for American Cars, Georges Dupuy, secretary, 1402 Broadway, New York City.
- June 14-29.....—Scottish Reliability Trial, Scottish Auto Club.
- July 2.....—Grand Prix, Automobile Club of France.
- July 14, 1908.....—Paris to London, Aerial Race.
- July 15-18.....—Ostend Week, Record Trials, Automobile Club of Belgium.
- July 21.....—Ardennes Circuit (Belgium).
- July 31.....—Liederkerke Cup for Touring Cars, Ardennes Circuit, Belgium.
- July 31-Aug 8...—Belgium Regularity Contest for Touring Cars, A. C. of Belgium.
- Aug. 1-7.....—Criterium of France, 1,750 Miles Touring Competition and 250-mile Race for the Press Cup, A. C. of France.
- Aug. 11-29.....—France, Coupe de Auvergne.
- Sept. 1.....—Italy, Brescia Circuit, Florio Cup, A. C. of Italy.

LETTERS INTERESTING AND INSTRUCTIVE

That Old, Old Best Car Question Crops Up Again.

Editor THE AUTOMOBILE:

[764.]—I see in the issue of "The Automobile" of May 16, that a Thomas car holds the record for climbing Mt. Hamilton. Now, as my father owns a car of this make (Thomas), I am very anxious to learn what car held the hill-climbing record before the Thomas, and what car it offered to help tow on the way up.

I would also like to ask which make of the following is, in your opinion, the swiftest, the best hill-climber and the best car to maintain: Thomas, Packard, Pierce, Locomobile, Peerless, Matheson, Lozier and American Mors. Also the one that you favor most. Will you please tell me which type of brakes you favor most, the internal expanding or external contracting.

A quick reply will be appreciated. WALTER SELIGMAN.
Cornwall-on-Hudson, N. Y.

Our communication from which the article you refer to was taken was silent both as to the name of the car which previously held the record for the Mt. Hamilton climb, or the car that was found stranded half way up and a tow offered, so that we cannot assist you in clearing up those points.

Your question regarding the best car made is one that has been asked ever since there has been such a thing as an automobile. If a hundred autoists were asked this question, it is very probable that there would be pretty nearly ninety-nine different answers, and each would be quite as conclusive and convincing in the estimation of its giver as it could possibly be made, if care had been taken to choose a hundred people who owned as many different makes of cars. Take it the other way round, and select a number owning the same make of car, and in all probability there would be a considerable diversity of opinion as to its standing, particularly with regard to detailed features of design and construction, as there are many, many owner-autoists who could have built their cars so very much better than the man who was responsible for it—in their own estimation, of course.

Automobiles have now reached a stage where the saying about pretty girls applies to them with equal force: all girls are pretty and all girls are nice, but some more so than others. The same is true of automobiles, with the further distinction that there is "the best car for the price," the "best all round car" and several other kinds of best cars. But the distinction you refer to on the score of hill-climbing is entirely a matter of changing the gear ratio to suit the conditions involved. A car geared for very high speed will be slow on the hills and vice versa, regardless of its make. Your list includes a number of the most representative makes turned out in this country, and the choice of any one is purely a matter of personal preference. Regarding your inquiry on the subject of brakes, the majority of modern cars are fitted with both types of brakes, usually placed on the same drums, fixed to the driving wheels. The internal expanding brake is generally pedal operated and is known as the running brake; the external contracting brake constitutes the emergency brake and is operated by the hand lever.

Methods of Radiator Construction.

Editor THE AUTOMOBILE:

[765.]—To settle a difference of opinion, can you tell me whether there are any standard and well-known water-cooled automobiles on the market to-day, in which the radiators are manufactured by electroplating the copper onto molds or forms?

Santa Fé, N. M.

MANUEL GUITIERREZ.

So far as we are able to ascertain, there are none. The Dufaux cars, made in Switzerland, were turned out a year or so ago with electrolytically-formed radiators, but we understand this construction is now given up. The De Dietrich cars, however, still have radiators built up of soldered-together members which are separately formed electrically. The difficulty that seems to prevent the general manufacture of complete radiators in this way seems to be with the thickness of the metal deposited, which it is almost impossible to get uniform.

High and Low-Tension Ignition Sparks Compared.

Editor THE AUTOMOBILE:

[766.]—In a recent issue you expressed the opinion that the difference in sizes between a jump-spark and a make-and-break cannot be responsible for much difference in time, and gave some figures as to the time required for flame to propagate from a minute point to a size as large as a make-and-break spark. I feel that you do not grasp the situation properly. You can readily see that a fire kindled in the middle of a house may take half an hour or an hour to burn the house, but that when one house is well started, it may set fire to and burn the next one in ten minutes. I mention this simply to bring out the fact that flame propagation is not necessarily at a fixed rate, and that it takes decidedly longer to ignite with a small spark which is barely hot enough to support combustion at all, than it does with a large spark which sets the charge going without delay. I consider it the difference between lighting a fire with a match and scanty kindling in one case and with a torch and ample kindling in the other; and believe it may take as long for a jump-spark to ignite a sphere of gas as large as a pea, as it does to ignite the remainder of the charge after the flame has gained this size.

I believe, and authorities on explosives make similar statements, that there is also a difference between mere ignition and detonation. If a charge of dynamite or gunpowder gives more velocity when fired with a percussion cap than when fired by a fuse or match, why should not an explosive charge of air and gasoline do likewise? Certain it is that considerable difference in power results when a large spark is used. This may be supposedly explained in connection with the jump-spark by saying there is less lag to the coil, which acts quickly with a strong current; but this explanation does not hold good with the make-and-break spark, which acts in the same time, regardless of strength of current. A make-and-break, as ordinarily constructed, must be connected long enough to give a full spark at the highest possible speeds of the engine. This means that it is connected too long with speeds lower than this, so there is no question about the coil being fully saturated, whether the current is full strength or not; and since the spark must occur at the same time, we can only assume that the strength of the spark affects the power of the engine, for there seems to be nothing else to account for this decided difference.

You mention that one spark may be hotter than another in some way not understood. I think the hottest spark propagates most swiftly, and that this partly explains, if not wholly, the difference. A comparison of size of the two sparks may interest your readers. It is well known that compression decreases the size of the jump-spark, but that the make-and-break arc follows the points as they separate and preserves the path for itself, so that it is not decreased by the compression. Also, whereas an engine with a weak jump-spark may refuse to fire at high speeds because of higher compression and yet fire readily at low speeds when the compression is less because of some leaks; the make-and-break spark shows the opposite tendency, and fires best at higher compressions. This simply proves that high compressions do not lessen the make and break spark, and shows that to properly compare without compression, the jump-spark should have its points widely separated, say one-fourth inch. With such points draw a sheet of paper between them while the spark is passed and hold it to the light so the minute holes burned by the spark can be seen. The amount of paper burned by each spark is the correct measure of its heat value. The make-and-break cannot be tested without a contact, so fasten a sheet of paper about 1-32 inch above a metal plate and with a sharp point like a pin make contact with the plate through the paper. Then suddenly, the quicker the better, break the contact and a large spark will follow the pin up from the plate, burning a hole in the paper 1-8 inch in diameter and frequently continuing to burn. When the length as well as the cross section is considered, judging from the comparative holes, it will be seen that the heat of the make-and-break spark is simply enormous as compared with the jump-spark.

Reading, Pa

CHARLES E. DURYE.

We take pleasure in publishing your comparison between the jump spark and the make-and-break or low-tension spark, together with your reasoning and deduction that the latter is the more efficient owing to its much greater size and consequent increase in heat. This with regard to the inquiry of Ralph Walker, letter No. 745, in the last issue of THE AUTOMOBILE. While the test you describe would appear to be conclusive as to the matter of the ignition capacity of the two types of sparks—or, in other words, their relative ability to set things afire, we think there is

considerable difference of opinion on this point when it comes to exploding the charge in a gasoline motor. It is conceded that the heat of the spark, whether at the primary or secondary terminals, increases proportionately with an increase in the current, from which it should follow that the greater the current used in the case of a jump spark system, the better the results to be obtained from the motor. But according to those authorities who have investigated the subject (the most recent and exhaustive report being that of W. Watson, D.Sc., F.R.S., whose paper read before the Royal Automobile Club, was published in *THE AUTOMOBILE* on March 21, 1907), this is not the case. It was there shown that apart from the greater magnetic lag in the core of the primary coil and the consequent need for more advanced timing, the use of a weak current short of one insufficient to fire the charge at all, had little or no effect on the indicator diagram given by the motor. Nor did the width of the gap between the spark plug points have any apparent effect on the power, the net result of the extended experiments made being that the power developed was the same whether a greater or less amount of current was used; or, in other words, whether a large or small spark fired the charge. There is a great deal to be learned on the subject, and we should like to hear from others who have made similar experiments or who hold theories of their own in the matter, as it is one of considerable general interest.

A Rather Puzzling Refusal to Start.

Editor *THE AUTOMOBILE*:

[767.]—I am enclosing a question for your valuable department "Letters Interesting and Instructive," and would be pleased to see an answer printed in that column in the near future.

I have a two-cylinder runabout that I have run for three years, with perhaps less than the usual share of trouble. But last fall it became so that I was unable to start the motor without pouring hot water over the carbureter, and that trouble has continued up to the present, in spite of the change in the weather, which is now warm. Even on a good warm day it is impossible to leave the car standing for an hour without having to warm the carbureter again in order to start. Squirting gasoline into the cylinders when only partially cooled off will start it, but in the morning this is not the case, for as soon as what has been injected is used up the motor comes to a stop. But once started, the motor never ran better than it does to-day. Before I could always start with a little extra cranking, even in winter weather. A reply will be greatly appreciated by
JAMES P. MELZER.
Milford, N. H.

Granting that there has been no change in the character of the fuel you have been using during the period in question, it would look as if the trouble you are experiencing was due to some carbureter derangement, such as the dropping of the float on its spindle, thus reducing the fuel level in the float chamber to such a point that it is impossible for the motor to draw any through the spray nozzle of the carbureter until it has been running some time, which would account for your inability to start by cranking. The effect of heating the carbureter would be to raise the level of the liquid and also to vaporize considerable of it which would then be forced through the nozzle, creating a mixture. The fact that you can always start by injecting gasoline through the petcocks shows conclusively that the failure of the motor to start on the crank is due alone to the lack of fuel. Exactly what constitutes the moving cause of the latter is somewhat difficult to say with certainty, though there appears to be little doubt but that the dismounting and thorough inspection of the carbureter should reveal it. Our opinion that it may be due to the cause outlined can naturally only be a theory under the circumstances, but it is probable that something similar will be found to be at the root of the trouble, though as a matter of fact, the action of the motor, as you describe it, coincides very closely with what would occur where kerosene or other heavy fuel is being employed instead of gasoline. If there are any of our subscribers who have experienced trouble similar to the foregoing and are, as the result, of having successfully overcome it, in a position to shed any light on the matter, we should be pleased to give their views space in this department. We would also be pleased to

learn the result of any experiments you make with a view to overcoming it, as the case is an unusual one and, accordingly, of general interest, particularly as difficulty in starting is generally the bugbear of the average autoist.

FOR AUTOISTS ENTERING AND LEAVING PARIS.

Editor *THE AUTOMOBILE*:

[768.]—Francis Miltoun's excellent articles on touring in France give a wrong impression of the highways around the French capital. Automobilists visiting Paris are apt to give a cursory examination of the map, select the widest and most direct road into the city, and curse all Parisian inlets ever after. I have had occasion to journey by bicycle, motorcycle and automobile on the highways around the fortifications too often to propose a benediction on their behalf. Certain stretches tackled in a light car with a dare-devil French driver at the wheel provide more sensations in five minutes than any other known sport in five days. But everybody who is more than a passing stranger to Paris knows that the paved highways need never be traveled over in leaving or arriving at the city. Francis Miltoun says that it is twenty kilometers of shockingly bad roadway to St. Germain, mostly pavé. True, if you take the main road along with the wheezy local train and the market carts. Wise motorists, however, leave the city through the Bois de Boulogne, cross the Seine at Suresnes, climb the Suresnes hill, turn sharp to the right under the railway, pass behind Fort Valérien, and reach St. Germain by a road comprising twenty feet of pavé and as many kilometers of excellent macadam. When advising travelers to stay at Versailles in order to avoid the twenty kilometers of nerve-racking road into the capital, Francis Miltoun must be thinking of the old highway via Viroflay and Sèvres. That too has been abandoned to the steam car and market cart, the modern road from Versailles to Paris being by the Côte de Picardie, Ville d'Avray, St. Cloud, Suresnes, and Bois de Boulogne. It is a hilly road, but, excepting the short Suresnes hill, has an excellent macadam surface, not an inch of pavé, and is moreover perfectly dustless, the entire twenty kilometers having been recently treated with tar. Rambouillet pavé is all Mr. Miltoun designates it; but there is a loop road at Rambouillet, all macadam, which removes the necessity of jolting yourself and your car to pieces through the old hunting town. A Taride detailed map of the environs of Paris will show how to get into the capital from almost any point without suffering pavé tortures. Any well-informed Parisian chauffeur will point out a score of routes which would have saved Mr. Miltoun unpleasant sensations on his journey into Paris. Good work has been done by the Touring Club of France in opening loop roads through or around pavé-stricken towns. Examples of this are to be found between Paris and Fontainebleau, the macadam loop roads being indicated by conspicuous sign posts. The loops vary in length from a couple of hundred yards to several miles.
W. F. B.
New York City.

A CHAUFFEUR AGREES WITH MR. ATKINSON.

Editor *THE AUTOMOBILE*:

[769.]—In this week's "Automobile" an article on "How to Extend the Life of an Automobile," by A. S. Atkinson, fully confirms what I have found out. I am a chauffeur driving for a private party, and by following the same kind of rules suggested by Mr. Atkinson I have found I have more time to myself and no road repairs to speak of; the car is always ready to go out at a moment's notice, and is in first-class shape. The following are a few rules that have helped me, and might be of service to others:

Always inspect the car at the end of a run, tighten nuts, etc. See that the oil is at the proper level and the grease cups are full; also that the gears have the right amount of oil and grease mixture.

See that batteries are connected and if the plug connections are tight, and once a week test batteries to see if they need recharging. Fill the tank and always strain the gasoline, using chamols or gauze; also strain all water that is put into radiator.

See that the tires are hard enough, and if there is a small cut in the shoe, fill same up with cement, for if you don't it will increase until a blowout is the result. A good plan is to put fresh air into the tires once a month and shift the shoes a bit, as they will not be so apt to rub in one place, and if my car has had hard driving for any length of time I shift the shoes, putting the front ones on the driving wheels.

Never leave the car with its gears in mesh. Always have the lever at the neutral point, making it foolproof.

The above rules have been invaluable to me, and may help some one else.
M. W. BATES.

Nutley, N. J.

RAMBLER MODEL 245 IS A SOLID LOOKING CAR.

AMONG the special designs listed by the makers of the Rambler cars at the opening of the season was their Model 24, embodying several distinguishing features, particularly in its transmission mechanism and rear axle unit. So successful has been the reception accorded this car that Thomas B. Jeffery & Co. have recently placed on the market two additions to their already complete line. These are known as Models 147 and 245, respectively, and are distinguished by the same features of construction and equipment as the Model 24, referred to above. The Model 147 has been designed particularly to fill the demand for a modern four-cylinder car with a comfortable seating capacity for five persons, to list at a very low figure. It will be evident from the following description of this car that its makers, with their tremendous facilities for turning out vehicles in quantity and their well organized purchasing and manufacturing departments, have scored very heavily in the production of Model 147. Neither quality of material nor workmanship has been sacrificed to make the lower price possible, the difference between it and the Model 24 being due solely to its smaller size, decrease in power; though it is, on the other hand, sold with a more complete equipment in that the selling price covers a cape top complete, with the usual front and side storm curtains.

Details of Model 147.—The chassis consists of a pressed-steel frame, strongly cross braced and supported on a suspension distinguished by the use of full elliptic springs in the rear and long semi-elliptics forward. The front axle is of seamless tubular construction reinforced by a solid bar, while the steering knuckles are extra heavy and are supported on ball bearings. The rear axle is the same as that used on the Model 24, the axle housing being of heavy seamless tubing made integral with the differential housing of cast aluminum by a special process controlled by the makers. The differential is of the spur gear type and is distinguished by the use of large pinions made integral with their supporting shafts. End thrust is taken up by means of a large ball bearing placed on either side of the differential case. The axle is of the floating type with the wheel ends of the shafts supported on roller bearings placed outside of the tube.

The motor has separately cast cylinders measuring 4 by 4 1-2 inches bore and stroke, respectively, and develops 20 to 25 horsepower at a moderate normal speed. The valves are located in the cylinder heads and

are placed in removable cages, thus facilitating their removal for inspection and repairs; they are operated by rocker arms actuated from a single camshaft, thus simplifying the design, while their placing is conducive to greater efficiency by facilitating the scavenging of the cylinder and reducing the area of the combustion chamber. This car lists, complete, at \$1,750, and by complete here is meant a full-sized cape top of good quality, side curtains and storm apron in addition to the regular equipments of lamps, horn and tools.

Rambler Model 245.—This is a 35 to 40-horsepower car which is distinguished from the model just described principally by the fact that it is equipped with a larger motor, and the car itself is made proportionately larger throughout to correspond. The motor measures 5 by 5 1-2 inches bore and stroke, respectively, and is of identically the same type as the one already described. It embodies a number of special features of design and the motor as a whole has been evolved by the Jeffery designers as the result of several years' experience in turning out a large number of cars, the majority of which are purchased by owners who drive their own cars, so that simplicity and accessibility have been held paramount. The matter of economy of maintenance and ease of handling have also been considered at length in order to meet the needs of this particular class of buyers as much as possible.

One of the features of chief interest about this car is to be found in its system of transmitting the power. It is provided with the new Rambler type of change-speed gear located on the forward end of the propeller shaft, thus dispensing with the use of a cardan joint at that point, while its position also brings the weight of the gear-set on the frame instead of the rear axle. It is of the progressive type of operation, but trouble from this source has been eliminated by the use of a balanced gear on the lay shaft. The driven pinion at the forward end of the lay shaft is not keyed direct, thereto, but is seated on the hub of a pair of radially extending arms. This member is keyed to the shaft and the arms project into openings in the web of the driven gear with a play of about 10 degrees. A pair of oppositely disposed springs in each arm serve to hold the latter normally in a balanced position midway between the two bearing faces in the web of the gear, so that in engaging the shaft is allowed to yield slightly, thus permitting the easy meshing of the shifting pinions.

MODEL 147 OF THE RAMBLER FAMILY, ANOTHER NEWCOMER.

NEW LINE OF CONTINENTAL MOTORS.

In order to meet the demand for a high-class motor to be used on high-powered cars, the Continental Engine Company, 503 Fisher Building, Chicago, has just brought out a new type, 45-50-horsepower motor, designed along lines favored by the best engineering practise of the day. It has been carefully tested and thoroughly tried out on the seven-passenger Pullman cars, built by the Pullman Motor Vehicle Company, Chicago, so that the makers are now putting a large lot through their works, an elaborate set of jigs, dies and templates being employed for exact duplication.

The cylinders, which measure 5 by 5 1-2 inches, are cast independently, the 13-4-inch .40 point carbon steel crankshaft being supported on five long bearings, the end ones of which are fitted with oiling rings. The cylinders are offset on the crankcase in order to reduce the thrust on the power stroke, and the same is true of the camshaft, which is offset from the plunger rods. This gives an improved balanced action, the roller type of plunger rod having

FIG. 1.—End elevation showing offset.

been superseded by a new disk revolving plunger rod which gives a positive action with a minimum amount of wear. The camshaft is a hollow piece of tool steel and is supported on three ample sized bearings of white bronze, the latter also being used in the main bearings of the crankshaft, all being of the die cast type.

The crankpins are hollow and the crankshaft as a whole is balanced after the flywheel has been bolted to the six-inch integral flange, the cranks being carefully aligned centrally with the connecting rods and cylinders. The connecting rods are of die-forged steel and are of I-beam section, with large light bearings at each end, closely fitted at the low or big end, and with provision for side play at the wrist pin. The pistons are care-

FIG. 2.—Side elevation of Continental motor, camshaft side.

fully ground in taper all over and only tip the scales at five pounds complete, the grooves and rings being carefully ground to a gauge sidewise to prevent any leakage. The piston pin is a hollow piece of hardened steel 1 1-8 inches in diameter, and is retained by a hardened steel snap ring in a groove about the piston so as to clear the cylinder, beside serving as an oil reservoir for the piston pin bearing. It will be noted that the exhaust valve is placed in the head centrally, while the inlet is at the side, though both are operated from a common camshaft. The former is seated in a removable cage, both this and its location adding greatly to the efficiency and convenience of the motor, as it provides a direct exit for the exhaust beside permitting the placing of the inlet and exhaust manifolds on opposite sides with but a single camshaft.

REMINISCENT OF MEDITERRANEAN BOAT RACE.

Discussing the seaworthiness or otherwise of motor boats, Georges Prade relates an amusing incident, not previously made public, of the Alger-Toulon motor boat race, in which it will be remembered all the boats but one finished their cruise at the bottom of the Mediterranean. The big automobile cruiser *Malgré-Tout* was towed out to Alger by a British craft which demanded \$10,000 for this little service. The motor was mounted on carriage springs, which broke during the voyage, placing the motor much lower than the propeller shaft.

The day of the race the engine was cranked with the shaft disconnected, and the boat went out of the harbor under sail, with the roar of the motor in a metal hull as an accompaniment. There was little wind, and the passage out of the harbor was so slow that when she reached the open sea the only craft visible was the torpedo boat destroyer appointed to act as escort. The skipper of the motor boat was an intimate friend of the commander of the torpedo craft.

"Where are the others?" he shouted.

The commander pointed to a few black specks on the horizon.

"All right, pass us the end of a tow rope. Make yourselves comfortable, boys."

The boys did make themselves comfortable; one took a violin, another squeezed and stretched an accordeon, and a third busied himself in the galley with the bouillabaise soup, in which the garlic was not spared.

Mahon was reached at night.

"Stand by to cast off; hawl on the main sheet, up with the jib; crank the engine," were the orders that rang out with a snap and a true accent of the Midi.

With her engine roaring, and her shaft as useless as a log, the craft entered harbor, where the enthusiastic population gave a true Southern welcome to the glorious but modest heroes of the sea, the victors of the trans-Mediterranean race.

TOLD TO ILLUSTRATE ABSENCE OF VIBRATION.

Here is a good and interesting story from the indefatigable press agent:

"Wm. H. Moffitt's 40-horsepower Lozier car left Islip, Long Island (forty miles from New York), one day last week, and before starting, the driver in searching through his pockets for a tool-box key, took out three coins and laid them on the running boards. One hour and forty-five minutes later, what was the driver's surprise on stopping on board the ferry at Long Island City to find these same coins on the running boards where he had left them.

"A story of a similar nature is told by Mr. Michener, demonstrator for the Lozier Motor Company. He, during the winter while taking a photograph of a Lozier car in a winter snow scene on the shore road, twenty-five miles north of the city, left a camera on the running board and did not discover it until pulling into the garage in New York City, it having remained in the same identical spot where it was left, not having moved during the entire trip of twenty-five miles over roads of snow and ice."

NEW JAW CLUTCH SLIDING GEAR-SET.

Endless schemes and innumerable modifications of the sliding gear idea have been created. An improved form of gear-set has been invented by Charles Cotta, of Rockford, Ill., who is now placing it on the market. The inherent limitations of size and space naturally restrict the amount of material that may be put

FIRST POSITION.

in the pinions themselves, so that no matter how good that material may be, the teeth of the gears always represent the weakest point of the entire device. To avoid the necessity of bringing the pinions together as much as possible, the selective type of gear-set in which there are two sliding spools, has come to

be the most generally used, and in designing his improvement the maker of the gear-set shown in the accompanying illustrations has taken advantage of this fact and still further improved on it as shown by the accompanying illustrations. This new gear-set provides three forward speeds and a reverse, while on the high-speed the drive is direct with all gears and the lay shaft idle. The pinions of the intermediate, slow and reverse speeds remain permanently engaged with the corresponding gears on the countershaft. They are bushed with bronze, and rotate loosely on the driven shaft. This does away with the necessity of constantly shifting them to effect the different changes of speed, and instead of the relatively small amount of working surface afforded by the gear teeth, sliding jaw clutches are provided as being much better adapted to withstand the shock of engagement, the maker's aim being to place a maximum amount of material where it is most needed in order to withstand the severe service required of a gear-set. The speed ratio is so arranged as to be uniform between the slow and intermediate and between the intermediate and high speeds. The highest grade of steel is employed and both shafts are supported on Timken roller bearings to minimize friction.

SECOND POSITION.

THEORY AND PRACTICE NOT IN ACCORD.

Many interesting calculations have been made as to the striking force of an automobile traveling at various speeds, a favorite being the mile-a-minute clip. According to these nimble figurers, the impact is so terrific as to be practically inconceivable, a car meeting an obstacle at this pace stopping with a force of several million foot pounds. Another has it that such a collision would be equivalent to dropping a car off the roof of a skyscraper. Taking these calculations at their face value, there should not be "a whole bone" left in the car, but this has seldom if ever been fulfilled in practice, as many of the cars that have made these sudden and unexpected stops have survived as far more than the assortment of disintegrated atoms pictured by the calculator.

UNIFORM COMPRESSION IN CYLINDERS.

As the design of multiple-cylinder engines for automobile service becomes better understood, and their use more general, the demand for smoothly running engines has increased, says E. J. Bartlett in *The American Machinist*. This is causing some manufacturers to devote more attention to uniform compression in the different cylinders. Unless the entire combustion space is accurately machined, which is usually impracticable owing to the valve and igniter cavities, there is liable to be enough varia-

FIG. 1.

FIG. 2.

Method of machining to obtain uniform compression space.

tion in the cylinder castings so that the power developed in the different cylinders varies to a noticeable extent. During recent tests on some medium-sized four-cylinder engines the fact was brought out that this variation may be several cubic inches in the different cylinders of the same engine.

When one considers that the explosive power is perhaps roughly four times the compression, as registered by a gage, it is not difficult to see that this variation should be guarded against.

A convenient way to overcome the difficulty is to design some of the inserted parts, such as the cylinder-valve plugs, so that more or less of the surplus metal may be machined off as required, as indicated by the dotted line in Fig. 1.

To avoid unnecessary fitting on the engine-assembling floor, several varieties of the plugs, taking up more or less of the compression space, may be machined and used as found necessary. Probably a limit of one-half cubic inch less or more than the normal capacity would be permissible.

For testing, a simple fixture like Fig 2 will be found advantageous. This may consist of a flat plate A, on which is mounted a dummy piston B of such length that when the cylinder C to be tested is set down over it and on the plate the top of the piston is in the proper relation to the top of the cylinder for the end of the compression stroke. A carefully measured amount of liquid, corresponding to the cubical contents of the compression space desired, may then be poured in through a funnel screwed into the plug hole in the top of the cylinder, and the plug adjusted until the liquid just fills the compression space.

SOME OF THE CAUSES OF RUST.

The rusting of iron is accelerated by the presence of copper, and retarded by such metals as tin, lead, zinc, manganese, aluminum or magnesium; the phenomena are to be attributed to the hydroxide of the metal, which dissolves in the water, for similar stimulating or paralyzing effects are produced on the iron by water which has been in contact with the metal, says *The Electro Chemist*. Arsenic and its compounds exercise a paralyzing effect on the rusting of iron, and when present in large quantities stop it altogether; in this case the dissolved iron hydroxide forms colloidal, ferrous, or ferric arsenite. Soluble salts such as the chlorides and sulphates of the alkali metals have a stimulating effect on the rusting of iron, probably due to their electrolytic dissociation, while among organic substances such compounds as sugar, phenol, or resorcinol stimulate the formation of rust; alcohol or methyl salicylate has a retarding effect, and acetic or salicylic acid dissolves the iron as rapidly as it is oxidized.

THE CHAUFFEUR'S "BINGEN."

By E. A. BRINNSTOOL

A speed-crazed automobilist lay groaning 'midst the wreck,
There were wheels and spokes about him and a tire adorning his neck.
A policeman stood beside him, while reporters, like a flash,
Gathered 'round with ready pencils as he told about the crash.
That nifty chauffeur faltered as he grasped that copper's hand,
Murmuring: "Just how it happend I can never understand;
Bear a message to my company and tell them of my fix,
And don't forget to say I went a mile in twenty-six.

"Tell the house for whom I travel of the daisy run I made,
That I kept the buzzer open and was not a bit afraid;
That I made four laps a-whizzing, and would sure have won the cup
If I hadn't had a puncture and the tire not blown up.
And oh, be sure you tell them of the five or six I killed,
Just before my tire exploded and I skidded and was spilled;
And if they want my record just before I made the mix,
'Tis here on my speedometer—a mile in twenty-six.

"Tell my mother though disfigured I am still within the ring;
That I made the run a-flying like a bird upon the wing.
For my father drove a trotter, and when I was but a child,
I remember how he told me of his races fierce and wild.
And when father died and left me I determined that my plan
Would be to follow after and become a racing man.
I have broken countless records—that was one of father's tricks,
But my Waterloo has met me in this mile at twenty-six!

"There's another—not a sister, but a pretty girl I know—
Who advised me when I started that I'd better go it slow.
And I thought about her caution when I crashed into this fence,
And I reckon she will score me for my lack of common sense.
Just say I couldn't help it, for I'm in the biz for cash,
And I have to take some chances and expect a frequent smash.
She may think that I am suited to be classed with lunatics,
Even though I broke the record by a mile in twenty-six!"

His voice grew faint and hoarser and his grip was limp and weak;
They poured some brandy down him, but he sighed and ceased to speak.
The "cop" bent down to lift him, but he only gave one glance,
Then telephoned the station to send out the ambulance.
And the soft moon rose up slowly and in pity it looked down,
As they dumped him in the wagon and then trotted back to town.
And his ante-mortem statement, just before he crossed the Styx,
Was: "Carve on my headstone simply:

BOOKS ON AUTOMOBILING.

A European Romance of the Automobile—Collectively, it is the usual plot of a villainous foreign count, a pretty girl and a brave Englishman which has been wound round "The Lady of the Blue Motor." If the descriptions of foreign scenes fail to arouse any vivid recollection of Paris and London, and the liberties which the author takes with foreign proper names, sometimes exceed ordinary limits, there is, however, the satisfaction of following the unwinding of a fairly good plot. Why the author should persistently make his characters pronounce "Monsieur" as if they were *faubourgien voyous*, or why he should tamper with the title of the world-renowned Café de la Paix, is not easy to understand. Though G. Sidney Paternoster cannot claim to have produced a masterly sketch of European automobile and racing scenes—and there is abundant raw material available for the word artist capable of handling it—he has the lesser satisfaction of spinning around the Lady in the Blue Car a romance of sufficient interest to hold the attention of the reader to the end of the volume. The book is published by L. C. Page & Co., of Boston.

A Handbook of Gas Engine Design.—The small volume compiled by Sanford A. Moss, M.S., Ph.D., under the title "Elements of Gas Engine Design," gives in a condensed form all the fundamental principles with which the designer of gas engines should be familiar. No attempt is made to go into mathematical or constructional details. In the opening chapters is given a general outline of the physics and chemistry of the gas engine and a discussion of gas engine fuels, followed by a table giving the relative power yielded by various fuels in a given engine. Other chapters give a discussion of the action in a gas engine cylinder from the designer's point of view, methods of finding the size of cylinders for a given power, rational formulas for most parts of a gas engine, with constants derived from modern American practice. Most of the work deals with the four-cycle engine. The work is published by the D. Van Nostrand Company, New York.

Homan's Work Brought Up to Date.—In order to keep abreast of the rapid and constant changes in design and construction that are taking place in the automobile, it is absolutely necessary for any work on the subject to be revised from time to time, as it would otherwise very soon be entirely out of date and merely of interest from a historical point of view. This has been done in the case of *Self-Propelled Vehicles*, by J. E. Homans, and the publishers, Theo. Audel & Co., in announcing the fifth edition, state that it has been thoroughly revised and brought down to date by the addition of a considerable amount of text and illustrations covering the advances made since the appearance of the previous edition, thus making it the most complete work of its kind extant. It is a neatly-bound volume of 600 pages, profusely illustrated with drawings and halftones, and covers the automobile of every type from every conceivable point of view.

New Road Maps for Travelers in Italy.—Valuable work for the convenience of the automobilist and general tourist is being performed by the Italian Touring Club in the publication of a series of fifty-eight road maps of Italy and adjoining islands. The first four of these are already out, and the remainder will appear at intervals, 60,000 of each being printed, making a total of three million and a half copies. Notwithstanding the large number of tourists who annually travel through Italy by automobile, no reliable road map drawn to scale had previously existed. This series is therefore particularly welcome, for it gives all the information required by tourists, such as distances, grades, curves, crossings, monuments, and interesting viewpoints. The maps are printed in seven colors, with all the mountains clearly defined, the work being executed by the Geographical Institute De Agostini & Co., of Rome.

BERLIN'S STREETS NOW SPRINKLED A LA MOTOR.

AUTOMOBILE FOR WATERING GERMAN CAPITAL.

BERLIN, May 1.—A new type of automobile street sprinkler has been added to the street department of the Berlin municipality. The wagon is driven by a gasoline engine carried forward, and has a huge metal tank with two powerful sprinklers in the rear. The throw of water outwardly is calculated to water the full width of the average street at one passage. Being as rapid as the average street vehicle, the automobile water sprinkler does not obstruct traffic, as is done by the horse wagons. As will be seen from the illustration, the capacity of the tank is at least four times that of the old type of vehicle.

MALAY PENINSULA AS A TOURING GROUND.

Automobiling in the Malay Peninsula is far from being an unknown art, writes J. H. Robson, a medical practitioner of Kuala Lumpur, in the State of Selangor. Mr. Robson was the first medical man in the Peninsula to use an automobile as a means of getting backwards and forwards to his home and office. Among the many machines which he has used in the Peninsula are a Stevens-Duryea, a four-cylinder Ford, a Cadillac, a Maxwell, and an Oldsmobile, all of which have given good service.

Perak, Selangor, and Negri Sembilan, the three States on the west coast of the peninsula have excellent roads, flat on the coast and hilly in the interior. A very interesting visit could be made to the peninsula by visitors to the Far East, by landing at Pinang from any of the steamers from Colombo, Madras, Calcutta or Rangoon, and overstaying fourteen days for the next steamer for China. This would give sufficient time for a detailed visit of the peninsula and would allow the tourist to see something of the rubber estates and tin mines. There are fully furnished rest houses, with boy and cook in attendance, at all the places a traveler would care to stay at.

Landing at Pinang, a very interesting trip may be made right through the States as far as the old British territory of Malacca, to the south of Negri Sembilan. The trip could be spread over four days as follows: First day, Pinang to Taiping, capital of Perak; second day, Taiping to Ipoh (Perak), a tin mining center; third day, Ipoh to Kuala Lumpur (Selangor), the Federal capital; fourth day, Kuala Lumpur to Malacca. The distances average about one hundred miles a day. Steamers do not come alongside at Malacca, so that, except in the case of small light cars, it would be well to work back again from Malacca to the chief port of Selangor (Port Swettenham). If arriving at Singapore, it would be necessary to tranship into a local steamer for Port Swettenham, for there are no roads up north through Johor, the mainland opposite the island of Singapore. There are no custom duties on automobiles. Gasoline costs about 80 cents a gallon, 100 cents equalling 2s. 4d. English money. A tourist would probably not be asked to take out a license if he had papers with him. At Kuala Lumpur, the Federal capital, there is an automobile garage. About twenty miles from the town is a very famous sulphur spring and public baths. From K. Kubu, twenty miles north of Kuala Lumpur, there is a railroad to Raub, in Pahang, crossing the main ridge of mountains and ascending for twenty miles at a gradient of one in twenty. The road is narrow, with many sharp curves, but a public automobile passenger service is running over the route. There is a gold mine at Raub.

A uniform automobile law applies to the four States of the Federation, and is largely based on the automobile regulations in use in England. There is, however, no speed limit, the rules stating that no automobile shall be driven at a greater speed than is reasonable or proper, having regard to other traffic on the thoroughfare. As in England, vehicles keep to the left-hand side of the road and pass to the right.

FIGHTING JAP SAILORS FROM THE WARSHIPS OF THE EMPIRE OF RISING SUN SEEING NEW YORK ON THE "RUBBER-NECK" AUTOS.

DARRACQ OFFICIALLY ABANDONS RACING

PARIS, May 21.—There has been a violent thunderstorm in French automobile circles, without any more serious results than usually accompany a summer disturbance. Wagner's departure from the Darracq factory to form one of the Fiat team in all the important European racing events this season was the primary cause of the trouble. Probably all would have passed off with a harmless rumble had not Smith Winby, the president of A. Darracq, Limited, written a letter to M. Darracq, in which he voiced his indignation at the news that the Fiat firm had seduced Wagner, their best driver, on the eve of important races in which their cars were to compete. According to Mr. Winby, the action of the Fiat company was so disloyal, and revealed an intention to conquer by every possible means, good or bad, legitimate or illegitimate, that only one course remained open, namely to withdraw all Darracq racing cars from every event in which they are engaged.

The move was of such an astounding nature, and so contrary to the general principle of the Darracq firm, the creator of racing, first in cycling, later in automobilism, that the public refused to believe it until M. Darracq himself gave confirmation in an interview with press representatives. "Wagner, our first conductor, the winner of the Vanderbilt Cup, in which he defeated all three Fiat machines, has been stolen from us by the Fiat firm, only a month from the German Emperor's Cup race, in which event he will be used against our team," declared the French constructor. "We can easily obtain other drivers, if not for the German event, at any rate for the later races, but I must protest against the spiriting away of our men on the eve of a race. If this is to continue, we shall see our drivers bribed over to a rival firm on the very morning of a race. For this reason we have decided not to race at all this season. Our cars will be offered for sale, and whoever likes to buy them will have the right to run them in the events for which they are already engaged, at their own risks."

A reply was immediately forthcoming from the Fiat firm, signed by Chief Engineer Marchesi, in which he declared that no attempt had been made to seduce Wagner. The Italian declared that Wagner had offered his services, and that there was no special monetary attraction, the salary paid him being that given to all their drivers. Wagner's proposition was accepted on May 1 because a few days previously Dr. Aldo Weillschott had announced his intention of no longer taking part in races.

Neglect of Signed Agreement Caused Darracq-Fiat Dispute.

It should be pointed out that the Darracq company is entirely to blame for any loss it may have incurred. Apart from the contract usually uniting a driver to an automobile firm for one or more seasons, and which would prevent such an occurrence as this, the rules of the Grand Prix stipulate that a written agreement should be drawn up between constructor and driver as soon after the engagement of the car as possible, and lodged with the Sporting Commission. Although it was understood that Wagner should drive for Darracq, no formal agreement had been lodged with the club, and he was consequently free to offer his services to any rival firm or to accept any offers.

Officially the Automobile Club of France and the German Club ignore the decision of the Darracq company. Three machines are entered for the Grand Prix, two for the Sporting Commission Cup, and three for the German Emperor's Cup race, entrance fees totalling 6,650.

Fortunately the Darracq machines will not be absent from this year's races. Hanriot, who entered the Darracq employ last year, has bought his Grand Prix racer, and will drive it in that event on his own behalf. Gustave Caillois, who had been engaged to drive for Darracq this year, and who was to have been entrusted

with a Sporting Commission racer, will very probably buy Wagner's machine and drive it in the Grand Prix, and the third, which should have been in charge of Demogeot, will doubtless go to Lee Guinness, the English brewer, owner of the eight-cylinder Darracq racer. Nothing is yet decided regarding the two Sporting Commission racers and the German Emperor's Cup racers, but it is certain that they will figure in the events for which they are already entered.

Wagner Explains and Protests.

PARIS, May 22.—Additional light on the Darracq-Fiat dispute is obtained by a letter from Wagner. The Vanderbilt Cup champion declares that he signed a contract as racing driver with M. Darracq on July 1, 1905, at a salary of \$60 a month, with a stipulation that the engagement could only be cancelled on either side by payment of \$2,000 indemnity. "April 27," says Wagner, "the Darracq firm proposed that I should sign an engagement to drive in the Grand Prix. I refused, for since my return from Sicily I had decided to leave them, and had already entered into negotiations with Fiat. On May 1 I told M. Darracq that I should leave his service, and immediately handed over the indemnity of \$2,000, as stipulated, this being a larger amount than I had earned in his service in two years. I have not compromised the firm's interests by leaving a month before the German Emperor's race, for at the time of my departure the car was not complete and I know nothing concerning its construction.

"On this occasion my reputation as a driver has been attacked by insinuations regarding the regularity of my stop in the Targa Florio. I was not able to finish because my machine broke down on the third round, while I was leading, as the result of a broken road wheel bearing. Hanriot had to stop for the same reason. I cannot allow it to be said that I have betrayed the firm, and I protest against calumnies calculated to injure my career as a driver. I shall ask the Sporting Commission of the A. C. F. to make an inquiry into my case and verify if it is not absolutely correct that I abandoned the race as the result of a mechanical defect."

CHRISTIE TAKES EARLY MORNING EXERCISE.

Since his first try-out on the Jericho turnpike, Walter Christie has made a few changes in his Grand Prix racer, and is now practising daily on a quiet stretch of road on Lang Island. By special permission he has the exclusive use of a four-mile highway every morning from 4 to 6 o'clock. The machine shows remarkable speed, and Christie is confident of securing a good position in the French race. Experiments are just about to be made to determine exactly the fuel consumption, the Grand Prix, as is well known, being run on a limited supply of gasoline.

FOURNIER RETURNS TO RACING GAME.

PARIS, May 21.—Unable to resist the fascination of racing, Henry Fournier, the victor of Paris-Bordeaux and Paris-Berlin, announced that he will pilot an Itala car in the German Emperor's Cup race on June 14. Fournier abandoned the racing game some years ago, after winning numerous events, introducing the first De Dion motorcycle into the United States in 1896, and later establishing a mile record in the neighborhood of New York. Of late years he has managed the Paris-Automobile garage in the Rue d'Anjou, one of the most important of Parisian swell garages, and certainly the one most frequented by American visitors. Before taking up the Itala agency Fournier did good business as the exclusive Paris agent for Oldsmobile runabouts.

PLEASURES OF AN AUTOMOBILE CAMP

By A. S. ATKINSON.

T IRED of the regulation vacation of a few weeks at seashore or mountain hotel, we decided last year to follow the gypsy plan and establish ourselves in an automobile camp. My wife demurred at first, as wives sometimes do when convention is to be trampled under foot, but two youthful chips of the old block cast the deciding votes.

"We'll go, and if mother wants to go to the hotel——"

But mother didn't want to be separated at vacation time from her brood. So she fell in with our plans and willingly assisted in the preparations. There were no particular plans. In fact, everything was rather indefinite so far as the route was concerned. We were simply to follow the life of the gypsies, substituting the motor car for the regulation gypsy wagon. We had no particular destination in mind, and we intended to live on the road for a few weeks either in camp or in riding.

"We'll be real gypsies, won't we, dad?" queried the youngest

phernalia showed us jointed poles which could be taken apart and stowed away in a three-foot space our difficulty was solved.

But a camp needs other things besides a shelter from dews of night. There was bedding to be provided, cooking utensils, and similar household equipments. The boys compromised on two hammocks—said they preferred hammocks to cots, and all Indians slept in hammocks slung from trees. I didn't know, and yielded to their wishes, but for myself I wanted a cot. The two hammocks were folded up and stowed away under one of the seats. Two cots and mattresses fitted snugly on top of the car with the tent, and, when neatly tied down, with blankets and linen, they were not very noticeable. Over all we stretched a waterproof blanket to protect the bedding from rain and dust.

The next problem was to find a place for the cooking utensils. My wife said we had to have a frying pan, a cooking pot and kettle, a broiler, tin pans, cups, saucers, plates, knives, forks.

ONE OF THE CHARMING CAMPING SPOTS WITH WHICH NORTHERN NEW JERSEY ABOUNDS.

of the boys. "Real gypsies are those who live in wagons and tents, and go about from place to place, ain't they?"

"We can't trade horses and tell fortunes, and gypsies all do that," replied the elder brother, scornfully.

But we did about everything that gypsies do that summer except trade horses and tell fortunes. Our auto was a good type of the touring machine, with seats for five, and amply supplied with lockers, hampers and ice-chest. It was made for long-distance touring, and when fully equipped we could cut loose from civilization for a considerable period of time without suffering any hardships.

But there were other things that we required besides the ordinary equipments for a regulation tour. The boys wanted to camp by the roadside—no hotel for them. They ruled the day, and we finally purchased for \$50 a tent large enough to accommodate four comfortably, with an additional wing for cooking in rainy weather. This tent, when rolled up, took considerable space on top of the car, but when folded neatly it could be concealed from view very well. The poles for the tent were the part of the freight which caused some discussion. I did not care to advertise our intention by sticking eight-foot poles from behind the body or top of the car. But when the dealer in camping para-

poons, and two dozen other articles. After much arguing the number was cut down one-half. She proved a good buyer, for she understood the economy of space as well as the economy of expenditures. She bought pans which fitted snugly into each other, and a kettle which neatly held all the cups and saucers. The plates just filled the bowl of the frying pan, and the knives, forks and spoons made the coffee pot full to the brim. When through with this sort of packing we had only five articles to stow away in the car. We decided to use the body of the car for these ungainly, but very essential, articles and the extra seat for our coats and wraps.

Then the hamper and ice-chest were filled. A small portable gasoline stove fitted snugly under one of the seats. A few dry groceries, such as tea, coffee, sugar, salt and pepper were kept in one of the scat lockers. We decided to do our marketing for the more bulky food as we moved along.

When we crossed the ferry for the shores of Jersey, we felt like an itinerant peddler ready to go on the road with a load of tinware to exchange for old rags and bottles. I listened to every jar, expecting to hear the tinware rattle and give us away. But I gained reassurance when I noticed that no one displayed any special interest in our outfit. Indeed, we did not look over-

loaded or much different from any of the other automobiles with us on the ferry boat.

We were filled with no vague forebodings after we struck the country road. Once away from the city, we bowled along happily, and spent the forenoon in enjoying the fine air and delightful scenery of the fresh fields and hills. We stopped at one of the small towns and purchased supplies for our first dinner. Then we scurried along to find a secluded place for the first camp.

In the hills of northern New Jersey there are many ideal spots adapted to such temporary camps. We found one late in the afternoon on the edge of a pretty little lake, with a stretch of woods back of it. Here, hidden away from all passers, we stopped, and the boys busied themselves in putting up the tent. I collected a few leaves and boughs for reclining seats, while my wife started the gasoline stove and prepared the supper.

Within an hour after we stopped the tent was up, beds made, hammocks swung, and supper ready. Hungry? We were literally starved, and food never tasted better. We ate so much that my wife looked anxiously at the remains, and remarked:

WHERE THE YOUTHFUL ANGLERS CAUGHT THE FISH.

"At this rate it will cost us nearly as much as if we put up at a first-class hotel."

"But the boys enjoy it, and they will gain a pound a day if they eat like this."

We had some nervous misgivings, my wife and I, during that first night in the tent. But the boys slept like tops, and in the morning they said their hammocks were the best beds they'd ever slept on. No strangers or prowling beasts disturbed our slumbers, but a few buzzing mosquitoes did trouble us. The next night we fortified ourselves against these pests by netting all the openings to the tent.

In the morning the boys plunged into the lake and had a bath that made them fit for any troubles and difficulties that might arise. Breakfast was prepared more leisurely than supper. There was no hurry, and the sun was hours high in the sky before the dishes were washed.

"Where shall we motor to-day?" I asked them.

"Why, I thought we were to play gypsies," replied the boys in a breath. "Gypsies don't move every day. They camp out, and then go on when they're tired of the old place."

"Want to stay here longer?"

"Yes, for I think there's good fishing in this lake."

So we decided to spend another night in the camp. The boys went fishing, and in the afternoon my wife and I motored to town to buy more of the necessities of life. We brought back so many that we were dismayed at their bulky appearance. We were really provisioned for several days. The boys had a fine mess of fish for us, and this added to our stores. They had already cleaned enough for supper, and fresh pickerel never tasted better than those which the boys prepared for us.

We lingered three days and nights at the edge of the lake. The boys were interested in the fishing and in exploring the woods. My wife and I took side trips, and spent the rest of our time idly reading and sleeping in hammocks stretched under the trees. Our camp was so secluded that we were not annoyed by any visitors, and when we finally decided to move on we actually felt a sense of disappointment.

We got an early start and covered a hundred miles before night, passing through picturesque, hilly regions and picking up our midday meal from a farmhouse, where fresh milk, eggs and fruits could be obtained in abundance. When night began to approach we found ourselves in a low, flat country, and there seemed no desirable camping place. Finally, in desperation, we struck camp near the roadside in a deserted field. That night our slumbers were disturbed by the croaking of frogs and the hum of hosts of insects. When morning dawned no one made a request to stay longer than necessary. We passed on gladly and made good progress toward more promising scenery.

We crossed Jersey and entered Pennsylvania. The country grew hilly and rougher, and the roads made our progress slower. At times we got lost and had to retrace our steps. But that did not annoy us. We had no objective point, and it all had its amusing side. We struck a small hill town and purchased more goods, and filled our supply tanks with fuel. We made inquiries about the mountain roads, and finally learned that we could strike an ideal camping place, thirty miles beyond, which would give us a beautiful view of three States—Pennsylvania, New Jersey and New York.

Fortune smiled upon us, and we pitched camp in an ideal nook under great spreading oak trees, with green moss for carpet, and a view from our front door that made the heart jump with pleasure. A trickling spring of water a dozen yards away made us feel at home. I knew that we were to stay there for some time, and so unpacked some of my books and papers. My wife was charmed with the view and insisted upon doing some painting. The boys wanted to play Indians and climb some of the neighboring hills and cliffs. I yielded to their wishes, and our camp became an abiding place for nearly a week. I suggested that we were not making the most of our opportunities for motoring, but I was silenced by my wife's remark:

"What's the use of making ourselves a slave to the automobile. We're here to enjoy ourselves."

Our wanderings that month were but a repetition of these few experiences. When we found a camp that particularly appealed to us we stayed until we had exhausted its pleasures, and if we camped in an uncongenial place we left it early the following morning. There were no restrictions to our going or staying.

It was this idle, unconventional life which made the whole vacation a series of pleasant impressions. Each member of the family dropped easily into the free life of the movable camp, and no grumblings came from any lips. The only protests were made when it was decided to head about and return home.

"What, so soon!" exclaimed the boys, who now looked more like two wild Indian lads than school boys.

Only business could break short such an ideal vacation. I yielded a little to their wishes by returning in a roundabout way, so that the trip was prolonged another week. Then we slowly trundled homeward, brown as berries, and so outrageously strong and healthy that we wondered what we would do to find an outlet for our animal spirits in the city.

As to the cost of the trip, I can only refer to my wife's remarks. She was the custodian of the funds, and kept the only accounts of expenses.

"Why, it has cost us a ridiculously small sum. It would have cost us twice as much if we had gone to a hotel for the summer, and the boys have lived in their old clothes. I haven't needed anything new, and what we've saved will fit me out with two new gowns, and there'll be something left for that pair of new lamps for you. And the boys were never so healthy! Look at them!"

I looked, and agreed with her. That fall I had my new lamps, and my wife had her gowns.

CLUBS PREPARING FOR THE SUMMER SEASON

Grand Rapids Club Has Tripled Its Membership.

GRAND RAPIDS, MICH., May 25.—If the Glidden tour doesn't come by way of Grand Rapids, local autoists will meet it in Chicago. They are now planning a tour to Milwaukee by boat from Grand Haven, thence by the Sheridan road to Chicago, to be at the latter place on the date set for the arrival of the tour. Probably 100 members of the club will make the trip.

The new country clubhouse at Cascade is to be open Decoration Day. The clubhouse has undergone extensive repairs to be put in readiness, and a manager has been engaged for the season.

The local club is keeping up its activity in fostering the State organization which has lately been formed. Among the tours that are planned for the summer are one to Kalamazoo and one to Muskegon, when special efforts are to be made to get those clubs into the organization. The club has made itself popular with the public by its stand on reckless driving. At its last regular meeting it appointed a committee to co-operate with the police department in its efforts to stop reckless driving, and the committee was instructed to draw up and have printed a set of rules for driving in the city streets. Everything possible is to be done also to discourage the driving of cars by children, which has been the cause of a number of accidents this season. Twenty new members were admitted to the club at its last meeting, making the total now 175. At the beginning of the season the list of members contained only 58 names.

More Cars Needed for Orphans' Day Parade.

NEW YORK, May 27.—It has been decided that the route for the Orphans' Day parade, to be held on June 12 next, will be from Seventy-second street, at or near Broadway, down the latter to the Brooklyn bridge, and from the other end of the bridge to the Ocean parkway, passing through Prospect Park en route, and ending up at Coney Island, where all the joys of Dreamland will be thrown open gratis to the children. Police Commissioner Bingham has offered the services of a number of mounted men in relays to convoy the parade, and it is probable that he may attend himself, using the big car that he has employed in testing the motorcycle policemen. It is understood that a well-known merchant has offered to supply luncheon to the party. Though a large number of cars have been offered, Chairman S. A. Miles, of the committee of the New York Motor Club, having the affair in charge, states that at least 100 more cars are needed to accommodate all the children from the institutions that have signified their intention of participating. Offers of cars should be sent to S. A. Miles, chairman, 7 East Forty-second street, New York City.

Long Island A. C. Will Locate Village Boundaries.

BROOKLYN, May 27.—Charles Jerome Edwards, chairman of the touring committee of the Long Island Automobile Club, has addressed letters to the presidents and boards of trustees of the different villages of Long Island, asking them to send an official statement of the boundary lines of their village corporations, as related to the main traveled highways, and if they are properly marked by warning signs. In connection with his letter, Chairman Edwards takes occasion to state that the Long Island club does not countenance excessive speeding of automobiles, or the violation of speed regulations, and has no sympathy for the persistent violator who drives his car at a 30 to 50-mile gait on the highways. On the other hand, it is the club's wish to protect, as far as possible, the careful driver, who may innocently exceed the legal speed, and pass into village boundaries without the knowledge of having done so. Mr. Edwards presumes that all of the villages have erected proper signs marking the boundary limits, but states that it is the wish of the club to erect such signs on its own behalf where they are missing.

Worcester Club Will Increase Membership Limit.

WORCESTER, MASS., May 27.—The Worcester Automobile Club will have its monthly meeting June 4. Plans are being made to have a change in the constitution and by-laws relative to the membership limits. At present the active membership limit is 250, and with the present list and the prospects which are in sight for active members there will have to be a change in the limit or there will be a waiting list of actives.

Members of the club and autoists in and out of the club all through Worcester county and city are to be invited to assist with their presence and cars in a parade June 20 in connection with the Old Home carnival which Worcester Merchants' Association will have June 17, 18, 19 and 20.

Word received at the Worcester clubrooms to-day was to the effect that Worcester will be one of the cities in Massachusetts where examinations and tests will be made under the legislative act which was signed by Governor Guild yesterday providing for a more rigid examination as a prerequisite for a chauffeur's license. This will do away with the present practice of making application for the licenses by mail.

Owners and chauffeurs both express themselves as satisfied to have a more rigid examination for the drivers of cars. Instances of cases where accidents have been caused by ignorance of the cars and their mechanism by their drivers were told by the owners, and the general sentiment was fairly expressed by President A. E. Bliss, of the Malden club, who was a caller at the clubrooms to-day, when he said there should be an issue of licenses similar to the licenses which are issued to engineers of stationary engines. These are on the basis of special licenses which permit the holders to run certain engines, and no others, and from that up through engines of different powers to the first-class license which allows the holder to run any kind of an engine.

President John P. Coghlin, of the Worcester club, is doing his short trips around the city in a new Studebaker electric runabout, and is leaving his big Aerocar for the longer trips.

CLUB DOINGS IN GENERAL.

Montclair, N. J.—The Montclair Riding, Driving and Automobile Club was organized recently. L. L. Chinn was elected secretary *pro tem.*, and other officers will be named at a later meeting.

Berkeley, Cal.—An automobile club has been born here. One of its main objects in life will be to obtain good roads and to assist the city superintendent of streets in keeping the thoroughfares in a worthy condition.

Chicago.—Mrs. E. V. Johnson has succeeded Mrs. C. H. Foster as president of the Chicago Women's Motor Club. Other officers are: Mrs. A. F. Chase, vice-president; Mrs. N. J. Boardman, secretary; Miss Anna M. Andrews, treasurer.

Davenport, Ia.—Good roads, reasonable legislation, a State association and some attention to social matters have been decided upon by the Davenport Automobile Club as lines of immediate conduct. It was also resolved to endeavor to obtain the services of Barney Oldfield at a race exhibition in August.

Omaha, Neb.—At the recent annual meeting of the Omaha Automobile Club a number of schemes were discussed for future activities. Good roads were decided upon as the most profitable field, and every effort will be made to improve the streets of the city. Present officers of the club are: Dr. F. N. Conner, president; Gould Dietz and Louis C. Nash, vice-presidents; Lee McShane, secretary, and Emile Brandels, treasurer.

Is It Possible to Eliminate the Change Speed Gear? This is a question that has been asked ever since the internal combustion motor was first adopted as a prime mover for road vehicles and there appears to be very little doubt that it will continue as a thorn in the side of the automobile engineer for a long while to come. For very obvious reasons it is one of those questions that simply will not down. Much has been done, it is true, but, in a certain sense, what has been accomplished has actually tended to leave matters further from the realization of this ideal than was the case at the outset. The necessities of the situation have been appreciated and a practical change speed gear developed from extremely crude beginnings; during the same period the motor itself has undergone a marvelous amount of improvement, but this has stopped far short of the culmination desired, and its shortcoming still looms up as large as ever.

There are occasional sporadic outbreaks on the part of the publicity man in organizing direct drive "stunts" to show the automobiling world in general that the change speed gear is no longer an absolute necessity on such a paragon of all the automobile virtues as he lauds—it is merely an emergency reserve and a friend in need for the inexperienced driver. But the manufacturer he represents and the majority of others still continue to put a four speed gear-set on their cars where formerly three were considered sufficient. Such performances as those referred to show what can be done by a skillful driver with a clear road, but forcing a motor of the present type until it is ready to gasp its last will not benefit it nor bring the sought-for result any nearer.

Cylinder multiplication has appeared to offer a quasi remedy for the evil, and so far as the use of the six and the eight-cylinder

motor has made it possible to do a much greater proportion of the driving on the high-gear, it may be said to have accomplished the object in view, but considered as a whole the problem remains practically unaltered. It is quite evident that the ability to start under load is an eradicable defect of any internal combustion motor of whatever type, and viewed at the present stage of development, it appears very likely that the need of an intermediate step between the motor and its load, constitutes a short-coming that falls in the same category, in any such exacting and variable service as that called for by the automobile.

The Overgrowth of an Interesting Principle.

"Shall we soon be running about the country on two-wheeled motor cars?" asks an English contemporary with all due seriousness, referring editorially to an invention involving the use of the gyroscopic principle to maintain a two-wheeled vehicle upright, which has been much exploited in the over-seas automobile press recently. "That such vehicles are possible has been proved," it goes on to say. "By means of two gyroscopes placed side by side, and revolving in different directions at enormous speed, the balance is maintained. The gyroscopes work on ball bearings in vacuo, and require little power to operate them."

Since the time when the gyroscope first saw the light in 1832, its possibilities as the basis of a wonder-working discovery have appealed very powerfully to the inventor. In practically the form that it has been known during the interim, it was originally invented as an educational device to demonstrate the principles of rotation, and the only other practical use to which it has been put beside this is in the gyroscopic top—familiar to the majority of schoolboys. Its applicability to the matter of rail transportation is something that falls outside of our province, though even in this field we seriously doubt if it will meet with any greater degree of success than would appear to be in store for it in connection with the automobile. To quote again: "If the new vehicle proves a success, there is no reason why we should not have motor cars with two wheels placed bicycle fashion."

There were those who ridiculed the idea of a man balancing himself on two wheels. That was a mere matter of trying and only the wheels were required; it does not require an engineer to realize that there are several "disturbing factors" in this new proposal. That it is possible, goes without saying, but the history of mono-rail schemes has been discouraging, particularly where they contemplated the balancing of a vehicle at high speeds. We already have plenty of two-wheeled motor vehicles in this country, but we doubt very much if we shall ever see any of the type our English contemporary so optimistically depicts.

Recognition of the Automobile by the Engineer.

For the first few years of its existence the automobile was a source of much comment, supposedly humorous, by the engineering profession, barring those particular engineers who were engaged in its construction, though no one within the charmed pale would ever admit that technical skill entered into the design or construction of an automobile in the early days. Then the profession began to think that probably there was something of merit in the alleged amateurism after all—at least, the success achieved compelled its own change of opinion. The culmination has come within the past year or two, for now the engineer engaged in other lines casts an envious eye on the automobile and hopes for the time when he will be able to specify "jewelry" steel for some of his constructions, such is the respect engendered by the great progress in steel making brought about by the automobile.

Probably the general change of opinion is best reflected in the fact that the American Society of Mechanical Engineers now deems the subject of automobile engineering of sufficient importance to devote an entire session of its semi-annual meeting to the consideration of some details of construction, on which papers prepared by well-known engineers were read.

A. S. M. E. HOLDS AN "AUTOMOBILE SYMPOSIUM."

INDIANAPOLIS, IND., May 29.—At its semi-annual meeting which is being held here this week, the American Society of Mechanical Engineers has devoted an entire session to the reading of papers on automobile construction. The meeting is a four-day affair and began yesterday with formal exercises in the auditorium of the Claypool Hotel, Prof. F. R. Hutton, of Columbia, making the opening address. This afternoon the engineers and their friends went in a body to make a round of inspection of the plants of the National Motor Vehicle Company and the Nordyke & Marmou Company. At this evening's session the following papers on different features of automobile construction were read, some of them, notably that by Mr. Hess, being profusely illustrated with lantern slides. "Air-cooling of Automobile Motors," by John Wilkinson, of the H. H. Franklin Manufacturing Company; "Bearings and Moving Mechanism," by Henry Hess, of the Hess-Bright Manufacturing Company; "Materials for Automobiles," by Edwood Haynes of the Haynes Automobile Company; "Special Automobile Steels," by Thomas J. Fay, and a paper on the "Railway Motor Car" by B. D. Gray. The automobile session filled the big auditorium of the hotel to overflowing and the papers aroused a great deal of interest. A large part of the remaining session is to be devoted to papers on superheated steam practice, including such phases of the subject as its use on American locomotives, its action in an injector, performance of superheaters and the determination of entropy lines.

SEARCHMONT CASE AGAINST A. L. A. M. DISMISSED.

On the ground that the plaintiffs had failed to establish a cause of action, the suit brought by the trustees in bankruptcy of the defunct Searchmont Automobile Company, against the Association of Licensed Automobile Manufacturers, was dismissed by Justice O'Gorman last week, sitting in Special Term, Part VI., of the Supreme Court, in New York City. In its ruling, the court states that, to all intents and purposes, the association is a co-partnership and subject to all the laws governing this relation—a decision that is bailed with considerable satisfaction by the plaintiffs, in that it definitely establishes the status of the defendant. However, as the latter complied with all the rules of the association in declaring the Searchmont Automobile Company no longer a member, the latter's rights were thereby forfeited, and cannot be revived. There is considerable interest in the decision on the part of the members of the American Motor Car Manufacturers' Association, as should the Selden patent not be upheld, and actions for damages be instituted against the licensed association, each of the latter's members, it is claimed, could be held separately liable.

PLANS FOR INDEPENDENT SHOW IN PALACE.

At a special meeting last week between the representatives of the American Motor Car Manufacturers Association and the Automobile Club of America, definite plans were agreed upon for the latter's eighth annual show to be held in the Grand Central Palace at Lexington avenue and Forty-third street. This is the extent of the information, however, as no details whatever have been made public as yet other than the fact that the Aero Club exhibit will also be a feature as at the past three shows.

NO CAR FOR THE NEW JERSEY COMMISSIONER.

TRENTON, N. J., May 24.—Governor Edward C. Stokes of New Jersey has vetoed the automobile appropriation bill, which gave \$4,500 to Commissioner J. B. R. Smith for the purchase of an automobile for his department. The Commissioner had the machine in this city and was operating the same in enforcement of the Frelinghuysen law. The car will now be returned to the manufacturers and a proposition is afoot to purchase motorcycles for the use of the Automobile Department.

TAXIMETERS HAVE NOW REACHED NEW YORK

New Yorkers will make their first acquaintance with the taximeter, the European instrument for measuring distance and recording the legal fare to be paid, on the morning of June 1, on the familiar electric automobiles owned by the New York Transportation Company. With the news that all causes for dispute between cabby and fare are to be removed comes the official announcement that the company will put fifty French gasoline taximeter cabs into service within ninety days. As to the nature of the vehicles the Transportation Company is mum; we are told to wait and see what we shall see.

It is only after a number of experiments that the Cosmos taximeter has been selected as the most suitable for New York condition. It is of German manufacture, and is mechanically very similar to all the instruments of this nature in use in Paris and London. A metal box with a large glass face, with openings on which appear the tariff, fare to be paid and extras, internal clockwork, and a flexible cable communicating with one of the road wheels, constitute the make-up of the apparatus.

"DISENGAGED" AND "ENGAGED" VIEWS OF TAXIMETER.

When a cab is hailed the driver lowers his metal flag surmounting the instrument, and causes either tariff 1 or tariff 2 to appear. The action of lowering the flag registers 50 cents on the payment opening, this being the minimum fare. At the end of the first mile the figures advance to 60 cents, and continue to advance at the rate of 10 cents per one-fifth mile. Should the cab be kept standing after being engaged, the instrument, by means of the internal clockwork, registers 10 cents for every six minutes. Tariff 1 is used when one or two passengers are carried. Tariff 2 is for more than two passengers. Under the higher tariff the rate of pay is 10 cents per one-tenth mile.

Extras are charged when a cab is called from the company's headquarters to any given address, the rate being 20 cents a mile. This is registered by the driver turning a small handle at the rear of the apparatus. In addition to informing the passenger how much he owes the cabman, the taximeter records, by means of a number of totalizers at the rear of the apparatus, the number of individual fares, individual amounts and total amounts earned, and total distance traveled by the vehicle. Thus not only is any dishonest dealing between driver and traveler an impossibility, but the company has a complete control.

Obviously the instrument is hermetically sealed and cannot be tampered with in any way. Excepting that the driver has to wind up the clock once a day, the apparatus is entirely automatic. On the hansom cabs the taximeter is placed near to the driver's right hand, the face being visible to passengers.

Judging from European experience, the initiative of the New York Transportation Company will be rapidly followed by existing rival cab companies, and the numerous automobile cab concerns at present in a nebulous state.

A YOUNGSTER WHO DRIVES HIS FATHER'S CAR.

Warren Willey, of Earlville, Ill., eleven years old, starting on his recent trip from Chicago to Fremont, Neb., in a two-cylinder Reo touring car. Although he can scarcely reach the pedals in sitting on the regular seat, he drove his father's Reo car during all of last season.

THOMAS DETROIT CO. TO ERECT NEW PLANT.

DETROIT, MICH., May 26.—Another great automobile plant is to be built in Detroit. The E. R. Thomas Detroit Company has announced the purchase of twelve acres of ground on the south side of Jefferson avenue, adjoining the new belt line, as a site for a new factory. All the preliminary arrangements have been worked out quietly, and the formal announcement was deferred until the first anniversary of the organization of the company. The E. R. Thomas Detroit Company began business a year ago, and during that time has marketed 500 cars. The new site for the company is four miles from its present location. The buildings will be constructed entirely of reinforced concrete.

The officials of the E. R. Thomas Detroit Company are: E. R. Thomas, of Buffalo, president; H. E. Coffin, first vice-president; R. D. Chapin, treasurer and general manager; J. J. Brady, second vice-president; F. O. Bezner, secretary.

Contracts for the new buildings have been let, and the factory will be occupied September 1. The cost of the plant, fully equipped, will be \$250,000. The old plant will be used temporarily as a storage place for stock.

H. S. HOUP TO HAVE QUAKER BRANCH.

PHILADELPHIA, May 27.—There was a brace of mild sensations in local automobile trade circles last week. The first of them was the announcement of the Harry S. Houpt Company, of New York, that it would about June 1 open a salesroom at 139-141 South Broad street, a stone's throw from the Union League and the Bellevue-Stratford Hotel. Andrew S. Robinson, a former Philadelphian, and later connected with the company's New York establishment, will be in charge. The entire Thomas line will be handled. The selection of the South Broad street location is looked upon as a master stroke.

The second sensation was the closing of a deal whereby the Keystone Motor Car Company, local Packard and Buick agents, will handle the Corbin car here.

THE WELCH COMPANY JOINS A. M. C. M. A.

With the admission of the Welch Motor Car Company, of Pontiac, Mich., to the ranks of the American Motor Car Manufacturers' Association, the membership list of the latter organization now boasts a total of forty-three automobile manufacturers. The latest entrant was long identified with the manufacture of gas engines before taking up the making of automobiles.

NEW COMPANY ORGANIZED AT JACKSON, MICH.

JACKSON, MICH., May 12. Jackson capitalists have organized the C. V. I. Motor Company, and will put a high-grade six-cylinder automobile on the market. The incorporators are W. S. Kessler, president of the Albion Malleable Iron Company; W. M. Thompson, president of the Jackson City bank; P. H. Withington and Winthrop Withington, of the Withington & Cooley Manufacturing Company; H. S. Reynolds, of the Peoples' National Bank, and H. L. Smith, of the Novelty Manufacturing Company and the Metal Stamping Company.

They will equip the car with an engine designed by C. C. Cutting and O. J. Porter. Some new ideas are embodied in the motive power. An experimental engine has been thoroughly tested out, with most satisfactory results. Messrs. Porter and Cutting are stockholders and will have charge of the mechanical end of the business. The company has rented the Hutchison factory at the east end and has placed orders for machinery and materials. It will put out a car which will sell for \$4,000.

THE 1907 PACKARD OUTPUT FINISHED.

DETROIT, MICH., May 27.—The last of a year's output of 1,129 motor cars finished and tested May 23, 1907, twenty-nine days ahead of schedule; "Bill" Birmingham, head tester, the happiest man in Detroit, and every Packard man, from the manager down to office boy, proud as there can be pride of accomplishment—this is the story of the wind-up of the manufacture of 1907 Packard cars.

When this last 1907 Packard "Thirty" had been tested, tuned and adjusted to its smallest detail; had passed the scrutinizing judgment of the head tester, and was ready to be washed and painted, the small army of hypercritics who compose the Packard testing corps roughly painted the rig in national colors, decorated it with all available flags and banners, crowded themselves into it, and paraded the streets of Detroit.

Each season the Packard company has progressed in the working out of a policy of one model a year, a definite number of cars of that model, and a definite schedule of manufacture and delivery. Last winter it worked against weather conditions which seemingly made the testing of cars on the road impossible. Drivers were compelled to face 10-below-zero cold snaps and all other forms of inclement weather that would seem naturally to retard such work. Back of "Bill" and his testers, however, was a system, with Henry B. Joy at the head, S. D. Waldon in charge of the sales organization, and Factory Manager Moore, with his assistants, working out the designs of Engineer Huff.

The Packard factory gradually turns from old work to new. Four experimental 1908 cars are on the road, going through a trial of many thousands of miles.

"BILL" BIRMINGHAM AND HIS CORPS OF PACKARD TESTERS.

THE GROWING GARAGE LIST.

A Modern Garage for Worcester.

WORCESTER, MASS., May 27.—An important addition has been made to the garage list of the city by the opening of the new Pilot garage, between Commercial and Mercantile streets. The building is absolutely fireproof, is built of brick, iron and glass, with granolithic floor, and has separate entrance and exit doors, avoiding the annoyance of turning cars round. The equipment consists of electric light, compressed air plant for inflating tires

WORCESTER'S LATEST UP-TO-DATE AUTO REPOSITORY.

and cleaning cars, electric polishing machine for brasses, electric motors, and a thoroughly equipped and up-to-date repair shop. A special waiting room with toilet has been provided for ladies, complete with writing tables, chairs, etc. There is a private telephone for the convenience of patrons. The Pilot garage is the local agent for Pope-Hartford, Pope-Tribune, and Pope-Toledo automobiles.

Cleveland's Latest and Most Modern Garage.

CLEVELAND, May 27.—Owing to the pressing demand, several departments of the Metropolitan Motor Car Company's new garage on East Nineteenth street, near Euclid avenue, were opened in advance of the completion of the building. The latter is 140 feet square and two stories high, both of which are exceptionally well lighted. An elevator runs from the basement to the second floor. The entire ground floor is an open cemented space, plugs for charging thirty electrics simultaneously being provided, as well as washing racks for five machines. Dry steam is piped from the heating boiler in the basement for removing oil and grease from running gears, thus avoiding the use of gasoline for this purpose, while compressed air is employed for cleaning upholstery. The upper floor houses the machine shop, tool room, woodworking, painting and varnishing departments, automatic fire doors being provided between all the departments. Two 250-gallon tanks underground outside the building, piped to automatic measuring pumps, constitute the fuel supply equipment. The company handles the Pierce Great Arrow, Stearns, Cadillac and Babcock electrics. The officers are W. C. Anderson, president, and J. Theodore Tehen, vice-president, both of whom have been connected with the auto trade in Cleveland for several years past.

Minneapolis Adds a New Garage to Its List.

MINNEAPOLIS, MINN., May 27.—The Evans Motor Car Company has just removed into its new garage at 522-24 Tenth street, S., within easy reach of the finest residential district of the town. The new garage, which is fireproof, built of reinforced concrete and steam heated, has a frontage of 45

feet and a depth of 100 feet. On the first floor are the stock rooms, office and garage. A fully equipped machine shop and storeroom occupy the second floor. Agencies are held for Mitchell, Wayne and Jewel automobiles.

Two New Garages for Asbury Park, N. J.

ASBURY PARK, N. J., May 27.—F. Engelsberg and R. Boone, both of New York, have leased the building on the corner of Lake avenue and Heck street, and will conduct a first-class garage this summer under the name of the Asbury Park Garage Co.

C. R. Zacharias has maintained his garage on the corner of Main street and Sewell avenue. Ker's garage is a new one opened on Main street, while Mark Guy still has the place at 21 Main street.

IN AND ABOUT THE GARAGES.

Cheyenne, Wyo.—A second garage has been opened here at the corner of Nineteenth and Ferguson streets. Fred Voss is the proprietor.

Pasadena, Cal.—John D. Laing intends to erect a large auto garage on East Colorado street, specially equipped for handling high-priced vehicles.

Algona, Ia.—Harry Wilson and Charley Lampright have opened an automobile garage here, and are prepared to do an auto livery business.

St. Paul, Minn.—In a few days the new garage for the Bazille Auto Company on East Ninth street will be completed and open for business.

Ottumwa, Ia.—Don P. McClure, of Oskaloosa, has opened a new garage 66 by 55 feet on Green street, with ample storage room and complete repair shop.

Buffalo, N. Y.—The Starin Company has removed from North Tonawanda, N. Y., to larger and well equipped premises at 1094-1100 Main street, in this city.

Topeka, Kan.—The Topeka Automobile Company is about to commence the construction of a two-story garage, at a cost of \$7,500. The dimensions are 75 by 50 feet.

Crawfordville, Ia.—Robert Irwin will open a garage on North Green street very shortly, where he will have automobiles for hire and additional space for storing machines.

Green Bay, Wis.—The Hoberg Livery & Auto Garage has just been opened for business in Main street. All modern appliances are to hand for storing and repairing automobiles.

Fargo, N. D.—The contract for the erection of the John Haas automobile garage, on the site of the old Columbia Hotel, at Broadway and Second avenue, has been awarded to Bowers Brothers, at \$7,992.

Winona, Minn.—Edgar Spence, of Indianapolis, Ind., has opened a new automobile garage on Center street, between Third and Fourth streets. The new business has been named the Winona Auto & Electric Company.

Seattle, Wash.—The new garage of the Seattle Automobile Company, on Tenth avenue, near Pike street, is nearing completion. The garage has a floor space of 36,000 square feet, and will be fitted with private stalls.

Allegheny, Pa.—The Allegheny Automobile Company has been incorporated and has opened a big garage at 915-919 Irwin avenue under the management of Walter G. Reineman. Glide and Austin touring cars and Rapid commercial vehicles are handled.

NEW YORKERS CAN SECURE OLD NUMBERS.

ALBANY, N. Y., May 27.—At the session of the legislature tonight the Assembly passed the bill of Senator Davis, which Buffalo auto owners wanted so that they might secure old registration seals and numbers. It is one of the few bills affecting motor vehicles passed this session.

BRIEF ITEMS OF NEWS AND TRADE MISCELLANY

A Pope-Hartford Model L has been selected as the official car of the Automobile Club of America.

An electric machine shop for the repair of automobiles has been opened by Mosley-Haigler Electric Company, at 308-310 Lee street, Montgomery, Ala.

A contract has been signed by the White Company for the equipment of their cars with Triumph gages made by the Boston Auto Gage Company of Boston, Mass.

J. D. Maxwell, president of the Maxwell-Briscoe Company, declares in favor of limiting the piston displacement of racing cars as the proper basis for handicapping.

King Alfonso of Spain has added a 22-horsepower Berliet victoria to his automobile stable. The machine will be used by the Queen and the recently arrived heir to the throne when they are able to ride out in the air and sunshine.

The Delphi Machine Company, of Delphi, Ind., has completed arrangements to increase its capacity to five times its present output, and a large building will be erected at once. The company has contracts for a large quantity of automobile parts on hand.

Los Angeles local dealers gave a royal entertainment to the public at its recent track meeting, the feature of which is reported to have been the performance of Harris Hanshue's 32-horsepower Reo Bird, which covered two miles in 1:59 3-5 and five miles in 5:4 1-5.

Foundations are now being laid for a new building adjoining the present Rambler factory, at Kenosha, Wis., to cover an area of 35,000 square feet and ten acres of land. This ground extension makes a total area of forty-five acres covered by the Rambler plant.

F. C. Gilbert, sales manager for the Pope-Toledo automobiles, says it is quite the fad now for purchasers to come to the factory when their car is ready, and drive it home, instead of having it shipped by rail. Distance makes no difference; in fact, the longer the journey home, the more enjoyable the drive.

The Byrider Electric Auto Company has been organized at Cleveland, O., by John and William A. Byrider, of Akron, O., to manufacture electric vehicles. The plant formerly occupied by the Williams Electric Company, at 1948 East Fifty-fifth street, has been purchased, and Fred B. Duncan, of Akron, installed as manager.

The car that was purchased by Motor Vehicle Commissioner J. B. R. Smith, of New Jersey, to run down speed violators was a Type XV Pope-Toledo. Mr. Smith states that "the car is not an extravagance, but an absolute necessity, and will give the department an immense advantage over the automobilists who insist on transgressing the law."

The plant of the Union Automobile Company, in Homewood avenue, East End, Pittsburg, Pa., was damaged to the extent of \$25,000 by a disastrous fire last Saturday. Small boys playing with matches near a lot of gasoline are supposed to have started the blaze. Of eleven automobiles in the garage two were completely destroyed. The garage will be rebuilt at once.

A large plant for the manufacture of denatured alcohol will be built at Cortland, Ohio, fifty miles north of Pittsburg. Twenty-five people will be employed, and the company, in which are included several Pittsburgers, expects to have the product on the market by midsummer. Machinery is being installed and large contracts are being made with farmers for potatoes, fruit and grain. The site is about midway between Pittsburg and Cleveland on the main line of the Erie Railroad.

At the first directors' meeting of the Carter International Automobile Manufacturing Company, Inc., of Detroit, held last week, the following officers were elected: President, Howard Carter; first vice-president, Louis Rosen; second vice-president, J. F. Crotty; secretary, G. F. Dueweke; treasurer, J. E. Winney; general manager, H. F. Koehler. The company manufacture the Carter two-engine car, which was originally produced in Milwaukee. Under the new corporation all interests are centered in Detroit.

Under the title of the Fargo Automobile & Brokerage Company, an organization has been incorporated in Fargo, N. D., with a capital of \$50,000, to do a general agency and garage business. The incorporators are Arthur Gehm, Fargo, president; Fred Lang, Grand Forks, vice-president, and E. H. Probstfeld, Fargo, secretary, treasurer and general manager. The company is already doing business, and handles the Thomas Flyer.

A remarkable automobile performance is reported by A. J. P. Bertschy and George Bertschy, of Reno, Nev. With a 1904 two-cylinder Winton runabout which had been exposed to the weather for twelve months outside a garage, a run was made to the mining camps over very heavy roads. The machine traveled to Boyer's Ranch, passed over Cobalt mountain, a rise of 6,600 feet, and reached Lovelocks in good condition. This is the first auto trip from Fairview to Lovelocks. The buckboard stage which makes this trip uses four horses.

In a letter just received by President Hartford, of the Hartford Suspension Company, from Chas. F. Hart, superintendent of the mechanical department of the Brooklyn *Daily Eagle*, he orders a new set of suspensions for its 1905 Pope-Toledo. In his letter, he states that the old set of suspensions has been on the car for 27,000 miles, of which 9,000 miles were over the roughest streets of Brooklyn delivering newspapers, with never a broken spring. This car has made some record runs in catching newspaper trains.

W. C. Price, 2222 Michigan avenue, Chicago, has just brought out a runabout equipped with a Beaver two-cylinder horizontal motor, with cylinders 4-inch bore and 4 1-2-inch stroke, driving to rear axles by means of a belt transmission from motor to jack shaft, and single chain to sprocket on rear axle. Variable speeds are arranged by tightening or lessening the tension on the belt. Solid tires are used, with 34-inch wheels, and the car complete weighs but 750 pounds. The maker claims great efficiency on all kinds of roads, and expects to form a company to put the cars out in quantity at an early date.

The Gemmer Engine Works, of Wabash, Ind., devoted to the manufacture of motors and steering gears, have been acquired by E. P. Hammond, A. Skae and E. Gemmer, all of Detroit, from the former owners, George Barcus and A. B. Rowley, the purchase price being reported as \$50,000. The business will be transferred to the latter city and will be housed at 741-747 Merrick avenue. Manufacturing will begin immediately, the plant occupying 200 hands in turning out the Gemmer steering gears, of which Mr. Gemmer is the inventor. The company has been incorporated with A. Skae as president; E. Gemmer, vice-president, and E. P. Hammond, secretary-treasurer.

RECENT TRADE REMOVALS.

The Duplex Ignition Company, makers of the Duplex spark plug, has removed from 1555 Broadway, New York City, to larger quarters at 307A West Thirty-sixth street.

The Rainier agency at Pittsburg, Pa., has removed its showroom to new and larger quarters at Seventh and Bedford avenues, and an ample garage will be operated in connection therewith in the future. B. F. Benson, who formerly handled the American Mercedes, has been appointed manager. In locating in the downtown section, the Rainier agency made a new departure in the Pittsburg automobile field, all of the others being located in the East End district of the city.

NEW AGENCIES ESTABLISHED.

The Pope Automobile Company, of Washington, D. C., has been given the agency in that city for the Autocar. The company's line now consists of the several Pope productions, the Locomobile and the Autocar.

A. W. Kirk, who formerly traveled in the South for the Hartford Rubber Works Company, will soon open a store at Atlanta, Ga., for the Hartford tire makers, and carry a complete line of its goods at that point. Mr. Kirk states that the demand throughout the South for the new Hartford Clincher and Dunlop tires with the Midgley Anti-Skid tread is exceptionally large.

The following new agencies have been established by the Corbin Motor Vehicle Company, of New Britain, Conn.: Charles Hanauer Automobile Company, Cincinnati; Flatbush Motor Car Company, Brooklyn, N. Y.; Keystone Motor Car Company, Philadelphia; Arrow Automobile Company, New Haven, Conn.; R. R. Kimball, Omaha, Neb.; Allen, Asten & Co., Greenwich, Conn.

The marketing of the Triple Action spring, the new spring for automobiles invented by D. R. Close, of the Garden City Spring Works, of Chicago, will be done by the Triple Action Spring Company, with headquarters at 1254 Michigan avenue, that city. S. Furmidge is the president of the new company; D. R. Close, vice-president, and Oliver G. Temme, secretary and treasurer. The spring was illustrated and described in *THE AUTOMOBILE* of April 25, page 727.

Cockcroft & Ballou, a newly established firm, have closed a contract with the K-W Ignition Company, of Cleveland, O., to act as American and foreign distributors for K-W ignition outfits. The firm has established headquarters at 122 West Thirty-fourth street, New York City, in a part of the store occupied by the Racine Boat Manufacturing Company as its New York branch, and will carry a complete line of the K-W ignition systems for automobiles and motor boats. The New York store will be in charge of J. D. Cockcroft, who will handle the eastern and foreign end of the business, while F. A. Ballou, with headquarters at 879 Main street, Buffalo, N. Y., will handle the middle western territory.

PERSONAL TRADE MENTION.

Charles B. Shanks, general sales manager of the Winton Motor Carriage Company, of Cleveland, is making his regular semi-annual visit to the Pacific Coast agencies.

H. L. Moody, formerly manager of the American Napier Company, of Boston, has joined the selling forces of the American Locomotive Automobile Company, at 1886 Broadway, New York City.

E. B. Blakely, the former Harvard student, who captured the 100-mile and other prizes at the Ormond Beach meet last winter, is now affiliated with the Electric Vehicle Company, and his future efforts will be devoted to Columbia cars. All the finished Columbias are passed along to Mr. Blakely for a final test before shipment.

Orrel A. Parker, president of the Newmastic Tire Company, Broadway and Sixty-eighth street, New York City, also a charter member of the Aero Club and a member of the committee on streets of the A. C. A., celebrated his marriage with Miss May Robertson Gibson a few days ago. The honeymoon took the shape of an automobile tour from New York to Chicago and back, largely over the route of the Glidden tour.

J. D. Maxwell and Benjamin Briscoe, of the Maxwell-Briscoe Motor Company, Tarrytown, N. Y., left last week for Newcastle, Ind., to inspect the erection of the new Maxwell plant in that city. Before leaving they stated that a circular half-mile track, heavily banked for testing the cars for speed, and an artificial hill with a maximum grade of 30 per cent. for hill-climbing tests, would be a part of the factory's equipment.

Robert L. Winkley, general manager of the department of publicity of the Pope Manufacturing Company, Hartford, Conn., has been visiting the Pope-Toledo factory at Toledo, Ohio. While there Mr. Winkley devoted a considerable portion of his time to riding with Herbert Lytle, the Pope-Toledo driver, over the excellent northern Ohio roads. In speaking of the healthfulness of automobilism, Mr. Winkley states that Lytle is a living exponent of it. He is up at break of day and on his machine, has an appetite that is the envy of his fellows, and looks like the fountain of perpetual youth.

GEO. C. JOHN'S CHANGE OF BASE.

George C. John is to become sales manager of the Pennsylvania Auto Motor Company, Bryn Mawr, Pa., and July 1 will assume his new duties. In the near future Mr. John is to leave the St. Louis Car Company, makers of the American Mors, of which concern he has been sales manager.

NEW TRADE PUBLICATIONS.

An advance 1907 accessories catalogue has been received from the Bishop Auto Supply Company, St. Louis, Mo.

"How Josh Lost and Won" is a story of—well it would be better to leave the reader to find out what it is about. The Columbus Buggy Company, Columbus, Ohio, will supply the booklet free on request.

Messrs. Adam Cook's Sons, 313 West street, New York City, the makers of Albany grease, are sending to the trade a new booklet, giving a considerable amount of information on the lubrication of machinery.

An eight-page folder from the Electric Vehicle Company, Hartford, Conn., supplies specifications and illustrations of the firm's six models of Columbia electric commercial vehicles. The illustrations on the folder are all made from photographs of Columbia vehicles in actual use.

A new booklet has been issued by the Diamond Tire Company, Akron, Ohio, giving descriptions and illustrations of the various types of Diamond tires, and paying particular attention to the Marsh rim. A series of illustrations show the mechanical parts of the rim, method of mounting, dismounting, etc.

Jones speedometers are presented in a dainty little brochure issued from the company's headquarters at Broadway and Seventy-sixth street, New York. The various types of speedometers for automobiles and bicycles are illustrated, and a colored engraving is given of the Jones triplet combination.

"The Why of It" is a folder from the S. F. Bowser & Co., Fort Wayne, Ind., telling the why of the well-known Bowser gasoline tanks. A further booklet deals with the Bowser system of factory oil storage; still another describes in detail the Bowser system for storing and handling gasoline and lubricating oils.

Voluminous, carefully compiled and well printed, the catalogue of the Auto-light and Motor Supply Company, 506-508 North Broad street, Philadelphia, contains all the multitudinous articles which the modern automobile demands. Everything from a cotter pin to powerful headlights has its place within the covers of the 140-page book.

With a closely printed volume of over two hundred and thirty pages, the automobile man should find everything he needs in the way of supplies and accessories. The big volume is issued by the Excelsior Supply Company, of Chicago, and contains descriptions and prices of everything likely to be of use or adornment to the chauffeur or his machine.

The Servitor model C automobile, constructed by the Barnes Manufacturing Company, Sandusky, Ohio, is the subject of a new catalogue just sent forth from the firm's headquarters. The machine is a 20-horsepower air-cooled run-about, full particulars of which are given in the catalogue in addition to illustrations of the interior and exterior of its birthplace.

With the regularity of rent day the Silent Partner appears. Volume two, number two, is as full of thought as its predecessors and will be read with as much interest. Its nature is too well

known to need comment. Those who have not studied its pages can remedy the defect by writing to the Globe Machine & Stamping Company, Hamilton avenue, Cleveland.

The annual catalogue of the Purdue University at Lafayette, Ind., is a 300-page volume forming a thoroughly complete guide to the equipment and courses of study at the university for the 1907-1908 session. It comprises a full list of officers, professors and assistants, an account of the material equipment of the institution, courses of study, and description of courses.

The new catalogue of automobile and motorcycle sundries which has just been issued by the New York Sporting Goods Company, 17 Warren street, New York, is a big book of one hundred pages, brimful of illustrations and descriptions of all sorts of motor fixings and accessories, with a few pages devoted to marine engines and boat supplies. A copy will be sent free to anyone who applies by letter.

There is something of real practical interest to the automobilist in Bulletin No. 20, issued from the Coates Clipper Manufacturing Company, Worcester, Mass. It describes in detail the construction of the Coates steel, ball socket joint, unit-link flexible transmission. In addition, drill presses, breast drills, buffing outfits, portable motor trucks, radial drills, etc., all equipped with the Coates flexible transmission, are described and illustrated in the catalogue.

From the Bayard-Clément headquarters has been received the firm's complete catalogue, in French, illustrative and descriptive of the wide range of automobiles produced in the modern factories at Levallois, near Paris, and at Mezieres in the Ardennes. There is a short sketch of the head of the firm, Gustave Adolphe Clément, the "industrial giant who says little but thinks much," and a description with illustrations of the main factory at Levallois, on the banks of the Seine.

Owing to the rapid development of the automobile and the radical changes from earlier models, it is a difficult problem to systematize and present in catalogue form all the multitudinous parts in regular demand. A work of this nature has been produced in an exceptionally simple and yet complete manner by the Pope Motor Car Company; Waverley Department, Indianapolis, manufacturers of the Pope Waverley electrics, in their catalogue of parts just received. The arrangement is excellent; illustrations are used throughout; parts are divided into groups, and are also indexed and numbered, so that any particular part can be readily found.

An exceptionally interesting and attractive book has been produced by the Continental Caoutchouc Company and forwarded to us by the New York agency at 43 Warren street, dealing with Continental tires in the Herkomer and other European contests. As a souvenir of the great German touring competition, the book will be welcomed by all automobilists, for it consists of over one hundred and twenty pages, each one bearing a half-tone engraving of some scene in last year's competition. The artistic cover bears a realistic photogravure of a speeding machine on the Herkomer course, and the frontispiece consists of an engraving representing Professor Hubert von Herkomer, donor of the trophy.

INFORMATION FOR AUTO USERS.

New Tire Tread Chain.—From the southwest, namely, Corsicana, Texas, comes another invention of the type designed to give traction at the driving wheels without grinding the tires to pieces in the operation. Its sponsor is

THOMAS' TIRE TREAD CHAINS.

J. Clarence Thomas, who is a Texas "auto-doctor," and he has made application for a patent on the device. As shown by the accompanying cuts of it, there seems to be every reason why it should successfully fulfill its mission, and no doubt it is the result of Dr. Thomas' ripe experience on the muddy roads of the southwest country. It is made in several forms, to suit the nature of the roads on which it is to be used; one of these not shown is in the form of a combined studded tread and set of chains, the latter fastening to side wires by means of hooks, as shown in the lower lefthand cut reproduced herewith, the side wires themselves also being fastened together with a small hook. The second of the three sketches shows a chain grip and smooth tread, and the lower or last figure a plain chain grip, all of the different types using the same method of side-wire fastening. Mr. Thomas has tested his invention over some of the choice samples of road that Texas has to offer and has found them to work very well.

Toggled Top Oil Cups.—Four types of Bennett toggled top oil cups are manufactured by the Bay State Stamping Company, 380 Chandler street, Worces-

STYLE A.

STYLE B.

ter, Mass. The two illustrated, Style A and Style B, are made to screw into the bearing with a threaded cover, with packing to make it perfectly oil tight. The

only difference between the two is in the cap, this screwing down in one case and slipping over the cup in the other. Two other styles are made plain to drive into the bearing. The cups are manufactured in three sizes, 3-8 inch, 1-2 inch, and 5-8 inch diameter of the cup. Prices vary according to size and method of construction.

A New Leather Tire Cover.—The Maplebay Manufacturing Company, of Crookston, Minn., has produced an automobile tire cover made of waterproof leather specially tanned for the purpose and guaranteed not to shrink or harden. The edges of the cover as well as the tread of same are protected from wear by steel plates, and the cover is fast-

MAPLEBAY LEATHER TIRE COVER.

ened to the wheel by steel clips which go under the edge of the clincher, making a very neat attachment. It is not claimed that the cover will prevent all punctures, but it is guaranteed to prevent a large proportion of them.

Conover Folding Wind Shields.—The distinguishing feature of the Conover shield is to be found in the fact that it is automatically held open or shut as desired, and can be instantly operated with one hand without the necessity of stopping the car, as is necessary where there are a number of nuts to be loosened and retightened. Just how this is accomplished will be clear from the three side views of the shield showing it in different positions. The first pictures it upright or in the usual running position; the second part way open, and the third, folded down. The spring D serves to control the upper half, whether in place or folded, while the catch E effectively prevents rattling when the shield is up. The rubber bumper I serves the same end when it is folded. The former fastening is made with rounded corners, so as to permit of its opening under

THREE SIDE VIEWS OF CONOVER FOLDING WIND SHIELD.

a sharp pull, so that all that is necessary to shift the position of the shield is to take hold of it. The shield is of 3-16 inch plate glass, while the frame and all the fittings are of polished brass, making it very attractive in appearance. It is made in three sizes, 24, 30 and 36 inches wide by 29 inches high, and readily adaptable to any of the standard forms of dash employed, and requires very little fitting. The Conover Motor Car Company, Paterson, N. J., are the makers.

Green Oil Soap for Automobile Cleaning.—So much expense and labor is lavished on the exterior finish of an automobile body that it is small wonder that the average owner soon becomes disgusted with the result of applying the so-called cleaning compounds to this brilliant surface after a short time. No varnish finish is ever subjected to more severe duty than that of an auto, and in consequence, much greater care is necessary if it is to preserve a semblance of its original brightness after a few months' use. The same care that keeps the varnish of milady's brougham gleaming bright day after day in all kinds of weather is necessary if the auto is to present the same appearance, so that the Monahan Antiseptic Company, 123 Liberty street, New York, who have been making green oil soap for the past fifteen years to keep varnish clean, know the requirements of the case pretty well. Garage keepers have come to recognize the efficacy as well as the economy of this soap for keeping cars clean and it is largely used in this city. It is put up in packages convenient for all users, viz., in 5, 10, 25 and 50-pound pails, and kegs, half-barrels and barrels.

Firestone Dismountable Rim.—The advantages to be derived from the use of a well-designed dismountable rim, are well known to automobilists, theoretically at least. Annoying delays on the road from punctures, and the risk of pinched tubes

from hurried wayside mounting are removed. The Firestone Tire and Rubber Company, of Akron, O., has recently produced a dismountable rim which will appeal alike to racing men and tourists. Safety is assured by a complete bearing surface, and a mechanical fastening which prevents creeping and absolutely locks the rim in position. To remove the rim, all that is necessary is to loosen the six nuts, allowing them to remain on the bolts, turn clips

FIRESTONE DISMOUNTABLE RIM.

FIRESTONE DUAL TREAD TIRE.

in the opposite direction, then tighten nuts to hold clips in that position; the rim may then be slipped off with ease. To adjust the extra rim with its inflated tire, this operation is merely reversed. A socket wrench is the only tool required. A feature of the Firestone is that should it be necessary the tire can be inflated without removing rim. In some makes the valve is cut so short that it is impossible to inflate, except when the rim is dismounted. The Firestone dismountable may be used in connection with all standard clincher tires and rims on any automobile wheel, the expense of changing being nominal.

Another new feature from the Firestone factory is a dual tread tire which provides the best non-skid feature in rubber, affords an added wearing depth, gives an additional protection against punctures and a wider surface contact with the road. The dual tread is somewhat thicker than the ordinary tread and consists of two ridges of rubber about 5-8 inches high and from 1 1/2 to 2 inches apart, extending around the tire. It is adaptable to tires of 3 1/2-inch size and upwards, and may be incorporated in any type during manufacture.

Hill Climbing Pump.—The Clark hill climbing pump, produced by Edward S. Clark, of 272-278 Freepoint street, Dor-

CLARK HILL CLIMBING PUMP.

chester, Mass., is designed to be fitted to White steam cars, model 1903 and 1904. The pump is shown in accompanying il-

lustration. The by-pass valve is fastened to the dasher. Pump bracket is made to bolt on to the frame that supports the engine lugs, only two bolts being required for this. The sliding block on the pump lever is hardened and is made to fit the pin that drives the air pump. It sets close to the engine and does not interfere with the regular pump connection. All the parts are sent with pump ready to apply, with exception of threading pipe, which has to be cut to fit the car.

Victor Adjustable Tire Holders.—The Manhattan Storage Company, of 1611 Broadway, New York, is now marketing a series of adjustable tire holders to fit any car and any size tire. One arm reaches forward and is fastened to dash, the other going to the end side of the front seat projection. They can be carried any distance apart to accommodate

SINGLE AND DOUBLE VICTOR TIRE HOLDERS.

the space on any car. Two qualities of the Victor adjustable tire holder are made, one of the best quality yellow brass composition, finely finished and highly burnished, the other finished in black japan. Each set is composed of three pieces, with straps, as shown in illustration.

Padgett's Detachable Rim.—The object of this invention is to provide a simple and mechanically dependable method of affixing a pneumatic tire to a wheel rim so that it may be readily removed and replaced with a minimum of time and exertion. James M. Padgett, of Topeka, Kan., is the inventor and patentee, and also has other inventions concerning the automobile to his credit, such as the "Stitch-in-Time" vulcanizer for road repairs to tires. As shown by the illustration of the rim, it consists of a band *F* with one outwardly curved edge on one side and regulation clincher retainer on the other, the latter being concaved and having two holes or recesses and a spring and pin *A*, integral therewith. A convex split ring *E* is adapted to engage the bead of the tire on this side, and is provided with a lug *B* at one

end and a corresponding hole in the opposite end. The operation of removing a tire from this rim simply consists in pressing on the point of the pin *A* until the end of *E* is freed; the latter is then lifted out of the concave recess and the tire may be

DETAIL OF THE PADGETT RIM.

slipped off with the hands. In replacing the tire, the lug *B* is first placed in the recess in the rim, and the flange *E* drawn together when the pin *A* springs into place. The bolt *D* is inserted from the inside of the tire, two or more being used to prevent creeping when run deflated.

Improved Bow Separators.—Under the name of "Stik-Tite," the Michigan Top Company, 14-16 Duffield street, Detroit, Mich., has just brought out a new form of bow separator that is said to be a great improvement over the devices now in use for this purpose. It is the invention of J. W. Decker and consists of two specially shaped pieces that are bolted directly to the bow, so that there is no possibility of their jarring loose or twisting away from the latter. The method of attachment to the bows is shown by the accompanying rough sketch; when the top is not in use and

THE "STIK-TITE" BOW SEPARATOR.

the bows are folded back on one another, the use of this device prevents their rattling and banging together and avoids any danger of breaking them in passing over rough roads.

Jersey's Big Club
 Finds Jersey's Roads
 Too Good
 BY
 A. G. Batchelder

A TYPICAL NOONDAY CONTROL—THIS ONE WAS AT FREEHOLD, N. J.

FOR three days the New Jersey Automobile and Motor Club required the participants in its endurance test to keep moving from early morn until late afternoon, but the conclusion found a dozen cars with perfect scores, several with minor losses of points, and only three obliterated from the 26 participants.

Of these, 14 belonged in the touring car class and contended for the possession of the William C. Shanley trophy. Seven survived flawlessly: Matheson, Stoddard-Dayton, Oldsmobile, Grout, National, Knox, and Winton. Incidentally the big National kept its hood on during the entire three days.

In the runabout brigade five of a dozen remained at the head of the class: Stoddard-Dayton, Corbin, Buick, Jackson, and Dragon, the latter handled by the experienced John Haynes and also having come from the factory without the semblance of an innings of testing—green and unlimbered.

It must be confessed that New Jersey's roads average exceedingly well, and, in fact, it is difficult at the present time, while observing the legal limits of speed, to give the present day automobile a question that it cannot successfully answer. Several years ago it certainly would have been another story.

On the first day of the Jersey event the motor-driven vehicles were asked to make the climb of Schooley's Mountain, and none faltered in making the ascent. On to Hackettstown the stone roads were excellent, and the route continued good to Washington, which served as the noon control and replenishing place both for man and machine. Between Washington and Somerville the road was a disgrace to the State Highway Commissioner, but from Somerville back to Newark nothing better could be asked for. The predicted rain failed to materialize, and the day's

enjoyable sort. Perhaps more so to the occupants of the non-schedule-following Frayer-Miller press car, handled expertly, even if occasionally somewhat recklessly, by Raymond Joo, who, I fear, at times slightly exceeded 20 miles an hour.

The return to Newark on Saturday was via Toms River, Lakewood, Freehold, and New Brunswick—139.5 miles—and it was just as thoroughly satisfactory and as completely within the power of the cars as on the previous two days. There were stretches of road with houses few and far between, which made one realize very keenly what a good Vanderbilt Cup course could be obtained in the confines of the "Mosquito State." But we saw no mosquitoes, possibly owing to the fact that the weather was a bit nippy but distinctly bracing for automobilizing. Truly it must have been somewhat irritating for the contestants to observe the exact letter of the law on those long stretches of highway where nothing moving was encountered except the auto in front that gave you its annoying dust.

BONNELL, DIRTY BUT VISIBLY HAPPY.

work summarized found only two missing of the 26 that started in the morning on the 121.9 miles circuit. This was on Decoration Day, which, being a holiday, found the people along the route in a receptive mood for the motor army.

From Newark to Atlantic City via Trenton stretch 154 miles of rattling fine road, and really it was so easy on Friday that it seemed a shame to consider that the task represented by many degrees what might be expected of the up-to-date automobile. Of course, President Walter E. Edge, Chairman Harry Cook, Secretary Johnston, and other members of the Atlantic City Automobile Club, in company with Mayor Stoy, were on hand to give greeting to Chairman Horace A. Bonnell and the pleasure party from Newark, for the day's run had been of the most

"JACK" MASON, ONE OF THE STODDARD-DAYTON PILOTS.

But we of the "press car," unshackled and taking advantage of the situation, passed the whole line, not once but repeatedly. There was Ralph Owen, he of Florida pathfinding fame, complacently jogging along with his Oldsmobile, in the tonneau of which were R. A. Greene and other subdued scorchers. Boland's big National was an unwilling monster held in leash, and "Jimmy" Ryall regretfully kept his Matheson in subjugation. "Dick" Newton, with Mrs. Newton pluckily occupying the rumble seat of the runabout—the observer being alongside the driver—pretended to be pleased with the leisurely pace, and John Haynes, of Vanderbilt Cup notability, waved a smiling salutation, though he must have itched to give his Dragon its head as we flew along. "Jimmy" Ferero, the kid of the run, handled the larger Matheson with a skill that evoked chunks of admiration from hundreds of youngsters, who enviously watched him with wistful eyes. "Jack" Mason had a hard struggle to keep his Stoddard-Dayton in check, and there were a dozen others who suffered similarly. Now and then there would be a burst of speed, but the offender knew that it would mean a funereal pace for him in the last mile before the end of the control, and this thought soon cured the contestants of any "speedstorm."

Infrequently we would run across Chairman Wiss and his Packard, which was a signal for our impatient driver to attempt a demonstration of air-cooling. Since we had a little more horsepower and our pilot had less regard for the law, it usually meant that our next mark was on ahead in the shape of the Thomas car containing Committeemen Wood, Kimber, and Cook, but because it was necessary for them to stop frequently to place road signs, they hardly gave us a run for our money. Vice-President Shanley, donor of the touring car cup, on the previous day had come in contact with a ditch which placed his Mercedes *hors du combat*, but in some miraculous manner the worst that befell us was a couple of tire punctures. Yes, the Frayer-Miller had speed to burn, and a good share was burned.

One of the features of the run was the Holsman, which completely answered the description of a horseless carriage in the

C. H. PECKWORTH WITH A LOAD OF KNOX TRAVELERS.

minds of the public, and its appearance was ever a source of deep interest to the farmers who viewed the auto procession. Though it accumulated a loss of points, the total was exceedingly meager, and on the concluding day it reached the finish line half a minute too early.

TOURING CAR CLASS FOR W. C. SHANLEY TROPHY.

JOHN HAYNES WITH THE DRAGON, FRESH FROM THE FACTORY.

THE SEASIDE, ATLANTIC CITY, WHERE THE PARTY RESTED.

Of course, it will not be possible to divide the Shanley trophy into seven parts, nor saw the Sinclair cup into five pieces. Therefore it has been suggested that the names of the winners in each class be engraved on the trophies and certificates be given to the clean score performers. Possibly the two sets of tied contestants may be assembled and a vote taken as to their wishes.

The three-day affair reflected much credit upon the endurance contest committee, and while Chairman Bonnell carried the bulk of the burden he was capably assisted by Committeemen Wood, English, Shanley, Kimber, Wiss, and Cook.

The total mileage of the three days was 415, and the schedule was carefully figured out and made to conform exactly with the requirements of the law. While rainy weather might have interfered to some extent with the most excellent showing, it is pretty good guessing that the tied cars might have been as numerous, for, as has been remarked before, the Jerseymen know the value of good roads, and they have been building them for some years.

fiscal year the effectiveness of this branch of the work may be increased by emphasizing the educational part of the work and increasing the mechanical facilities. To do this it will be necessary for the Government to own the road machinery and have such transportation facilities as to permit an accurate schedule to be followed in carrying on work at different places.

RALPH OWEN, THE OLDSMOBILER.

A plan will then be put into operation by which all of the road overseers in a given county will participate in the object-lesson work at stated times, and a series of practical lectures setting forth the elementary principles governing road construction, as applied to the particular locality in question, will be delivered during the

THE BIG SIX-CYLINDER NATIONAL PASSING THROUGH A CONTROL.

Observing to the letter the present—but some day to be obsolete—speed limits, it would appear to be practically impossible to evolve an eliminating endurance run over as many miles of Jersey road as can be traveled between sunrise and sunset by most autos.

FRAYER-MILLER "PRESS" CAR, WHICH ENJOYED THE FINE ROADS UNHAMPERED BY SCHEDULES

WHAT THE OFFICE OF PUBLIC ROADS IS DOING.

WASHINGTON, D. C, June 1.—Logan Waller Page, director of the Office of Public Roads, has given THE AUTOMOBILE corerspondent an outline of his plans and recommendations for 1908. While the object-lesson method has been in use for some time by the office, it is hoped by Mr. Page and his associates that by the next

construction of each object-lesson road. An estimate has been made for eight additional engineer students. The benefit, both to the government and to the individual student, are so decided as to justify increasing the scope of the work as far as possible.

NATIONAL GOOD ROADS BODY PROPOSED.

A movement is on foot for the formation of a strong national association to deal with the good roads problem, incorporating all existing associations paying any attention to this matter. A preliminary meeting was held last Tuesday at the offices of the National Association of Licensed Automobile Manufacturers, attended by representatives of the A. L. A. M., A. A. A., A. C. A., American Motor Car Manufacturers' Association, and the National Association. Only routine work was done, but it was decided to call a representative meeting at the same place on June 27. There is entire unanimity on the proposition to form a strong representative body, which would be infinitely more powerful than the numerous associations at present working individually on this question.

YOUTHFUL MATHESON "JIMMY" FERERO.

HOW THE LONG ISLANDERS TRIED OUT THE AUTOS *By W.F. Bradley*

SPEEDING ALONG THE ROAD THAT SKIRTS THE SHINNECOCK HILLS—CANOE PLACE INN AT THE RIGHT.

“A GOOD machine that is certain to finish?” repeated the Long Island Automobile Club official.

“Take the Pope-Hartford; Mr. Arnold will be sure to come through with a good score.”

Three minutes later the red machine from Connecticut, with C. G. Arnold at the wheel, a speed-loving architect beside him, and the tonneau occupied by an enthusiastic tire man and a breakfastless representative from *THE AUTOMOBILE*, was running down Cumberland street, Brooklyn, leaving a round dozen cars to follow in its rear.

It was an easy matter to select a car that would finish, and finish without a black spot against it, for of the twenty autos that set out for the club's endurance run only a sprinkling fell by the roadside. To select the one that would comply with all the conditions of the test and finish the run ahead of all competitors in its own and higher classes displayed an acumen on the part of that official which many a racing man would give his shirt to possess. Out through the Plaza, Eastern Parkway and Highland Park the police had not got up, but they had rolled a few boulders into the middle of the highway as a friendly invitation to the autoist that he might speed round them if he wished. It is an excellent idea for obtaining a vicarious service and reflects credit on the bicycle “cop.” When Flushing had seen our tail number the Pope-Hartford began to stretch out to such an extent that the “fifteen an hour” which the regulations demanded appeared as if framed for a cross-town horse-car. Columbia, Aerocar, Thomas, Queen and Olds, in our own class, and Cadillac and Maxwell in Class A, were successively left behind by the Pope-Hartford and its strenuous driver. The last to be overtaken was the Holsman buggy, an early starter which had plodded along with remarkable regularity.

Down Manhasset hill, where the two-wheelers were preparing for their onslaught on speed records, through Roslyn, Glen Cove, Oyster Bay, Cold Spring Harbor, Northport, Stony Brook, then a sharp dip down into Port Jefferson, where our early arrival caused us some difficulty in finding the Miss Smith who had been delegated to feed the troupe. After running right through the village, returning, and taking the ubiquitous small boy on board as official guide, Miss Smith's hotel was discovered where it would have been found at first glance had we not been too eager to arrive first. Hardly had the Pope-Hartford checked in than the Olds, the Thomas, the Cadillac and a number of others lined up. When the hurried lunch had been disposed of and the first arrival was ready to resume its run eastward, all had arrived within the regulation time except F. Rockliff's Aerocar. Rough handling when hard pressed by an inconsiderate buggy driver had caused a smash-up of the transmission and a forced abandonment of the contest when it was barely begun.

We were badly placed for observing the afternoon run. The leading car, our driver was determined to retain his position of honor and left no opportunity of lingering over the beauty spots or going softly where the highways were abandoned for the dirt roads. The route was direct east by Wading River, Riverhead, Mattituck, and Southold to Greenport, where the Pope-Hartford made its first stop of seven minutes to fill up with gasoline and lubricating oil.

Out to Orient Point was a wild rush in which the chickens suffered. The checker was shaving upstairs when we ran into his rear garden, and it was five minutes before he dropped the lather brush to sign the control card. When we turned westward again for the night control at Greenport the most formidable of the competitors, Oldsmobile, Thomas and Columbia, had crept nearer and

WHERE A BREAKDOWN WOULD HAVE BEEN AWKWARD.

AEROCAR STARTING ON THE TWO-DAY RUN.

AIR-COOLED FRANKLIN REACHING GREENPORT.

were passed by us between the two towns. At 1:52 we were checked in at Hedges garage, Greenport, the 139 miles having been covered in 4:51:7. When the others arrived and times were compared, the Pope-Hartford had to abandon its proud position to its half cousin, the Pope-Toledo, which finished in 4:03. Twenty had started out from Brooklyn; nineteen had finished, all of them well within the time limit allowed, and quite a number with clean scores. Their names are:

CLASS A, COSTING UP TO \$1,500, 12 MILES AN HOUR.

Holsman, 10-horsepower; driver, W. J. Hunt.
Cadillac, 10-horsepower; driver, J. D. Rouk.
Maxwell, 16-20-horsepower; driver, I. C. Kirkham.

CLASS B, COSTING \$1,500 TO \$3,000, 15 MILES AN HOUR.

Pope-Hartford, 30-horsepower; driver, Chas. G. Arnold.
Oldsmobile, 40-horsepower; driver, R. E. Pardee.
Thomas, 40-horsepower; driver, W. H. Bower.
Queen, 30-horsepower; driver, A. D. Corwin.
Aerocar, 40-horsepower; driver, A. M. Robbins.
Columbia, 28-horsepower; driver, E. H. Barnum.
Haynes, 30-horsepower; driver, John Sleber.
Franklin, 20-horsepower; driver, R. G. Howell.

CLASS C, COSTING \$3,000 UP, 18 MILES AN HOUR.

Pope-Toledo, 50-horsepower; driver, A. N. Wilcox.
De Luxe, 50-60-horsepower; driver, Chas. Beach.
Matheson, 40-horsepower; driver, R. G. Kelsey.
Packard, 30-horsepower; driver, S. H. Burns.
Pierce Arrow, 40-50-horsepower; driver, A. B. Coles.
Dolson, 60-horsepower; driver, F. A. Cole.
Welch, 50-horsepower; driver, E. L. De Camp.
Winton, 40-horsepower; driver, C. A. Carlson.

Stories over drinks failed to bring any more exciting incidents to light than the sinking of R. G. Kelsey's car into the sand near Fort Salonga, from which position it was rescued by the Welch;

the carrying away of a couple of carriage wheels by R. G. Howell's Franklin, and a might-have-been upset of the Pierce and the Columbia when avoiding other users of the road.

The Homeward Second Day's Journey.

All observers were turned round before the homeward journey began on the following morning, to the delight of those who were dissatisfied with their machines and the regret of those who would leave well alone. In place of the tire magnate, the Pope-Hartford had been given a short-legged Standard Oil potentate as official observer, who smiled approvingly when the speed was moderate in the villages and scowled ferociously when his length, or lack of it, prevented him wedging in securely for the frequent wild runs.

Class B was closely bunched for the first fifteen miles, and we were at least half a dozen who ran into Southold together, where a U. S. official watched the snail crawl, watch in hand. Another half hour and they were all shaken off but the Olds runabout, which hung persistently on our heels. On the dirt road leading to East Quogue the persistent Holsman was passed. The Maxwell, a hundred yards further ahead, could not be got round for ten minutes, owing to the impossibility of finding sufficient width in the hedged-in track.

Over the Shinnecock Hills to Southampton was a magnificent ride with roads that gave sufficiently easy running at fifty an hour to enjoy the beauties of sea and land. Near Bridgehampton's liberty pole the checker recorded the time and the eastward run was begun again with the Shinnecock Inn as noon checking point. There was an exciting little struggle on the moor near the checking station between the Pope-Hartford and

WINTON ON THE SHINNECOCK HILLS, WHERE GOOD ROADS AND FINE VIEWS CHARM THE TRAVELER.

PERSISTENT HOLSMAN WAS A FEATURE.

CLEAN-SCORE POPE-HARTFORD.

MAXWELL, AN EX-GLIDDENITE.

the little Cadillac. Twice the small machine took the lead owing to the Hartford getting on the wrong track, and when the station was reached there was only a difference in our favor of one second, ignored by the checker.

Out from Shinnecock Inn to Brooklyn was a solitary run with no competitors in front and no sight of them in the rear, where the indicator sometimes ran up to "55" and occasionally dropped down to "8," as the nature of the country demanded it. Even the Standard Oil king forgot that he was being tossed about like an abandoned bottle as he exclaimed: "We shall beat all the other fellows by an hour at least." But we did not, for we had not even wiped off the dust when Pardee pulled up his Oldsmobile outside the club premises. De Luxe was at his heels, Pope-Toledo was but ten minutes behind, and Cadillac chuc-chucced in ahead of a lot of the big fellows. Although all the machines had added to the strenuousness of the test by running at a speed far in excess of that demanded by the regulations, there was only one absentee, the Haynes machine, which skidded on a sharp turn at Mattituck, broke a wheel and ditched. The Thomas had a loose connecting rod and came in late in consequence. The Queen had to undergo carbureter adjustments and the Franklin broke its fan. Ten cars, however, finished with clean scores; in other words, ten out of twenty starters covered nearly 300 miles with no stops except at controls and with no other attention than filling the oil and gasoline tanks. It would be impossible to have more convincing proof of the reliability of the modern American automobile.

It remains for the committee to decide how the trophies—the

Brooklyn *Life* Cup, Brooklyn *Eagle* Cup and Shinnecock Hills Cup—shall be awarded, the most probable solution of the difficulty being a final contest between the ten competitors. The machines are placed as follows:

CLASS A, MACHINES COSTING UP TO \$1,500.

Maxwell, I. C. Kirkham, clean score, tied.
Cadillac, J. D. Rouk, clean score, tied.
Holsman lost nine minutes on carbureter adjustments.

CLASS B, MACHINES COSTING FROM \$1,500 TO \$3,000.

Columbia, E. H. Barnum, clean score, tied.
Oldsmobile, R. E. Pardee, clean score, tied.
Pope-Hartford, C. G. Arnold, clean score, tied.
Queen, carbureter adjustments; Thomas, loose connecting rod; Franklin, broken fan; Haynes, disabled; Aerocar, changed cooling water.

CLASS C, MACHINES COSTING \$3,000 AND UPWARDS.

Matheson, R. G. Kelsey, clean score, tied.
Packard, S. H. Burns, clean score, tied.
Pope-Toledo, A. N. Wilcox, clean score, tied.
Pierce Arrow, A. B. Coles, clean score, tied.
Winton, C. A. Carlson, clean score, tied.
De Luxe and Dolson had carbureter adjustments; Welch broke pin in oiler.

TO HAVE AUTO INSTEAD OF HORSESHOW.

BUFFALO, N. Y., June 3.—President Robert W. Pomeroy, of the Country Club, one of Buffalo's fashionable social organizations, has announced that the club will not hold a horse show this year, as has been the custom. It has been decided to hold an automobile show instead. The date will be announced later.

CHAIRMAN EDWARDS, WHO WAS ALWAYS AT WORK.

LEAVING GREENPORT FOR HOMEWARD JOURNEY.

WALTER C. WHITE IN HIS WHITE STEAMER CLIMBING WILKES-BARRE MOUNTAIN (GIANT'S DESPAIR) IN 1:49 4-5. **EN**

WILKES-BARRE, PA., June 1.—While the mountain back of this city may be the despair of giants, it is just pie for the present-day American automobile. Indeed, after Decoration Day's happenings it might be well to change the name of the crack 6,000-foot hill to "Automobilists' Delight." Certainly every one of last year's records was knocked galley west, and new figures established which it would seem could not be materially bettered—at least for several years.

To illustrate: The course record of 2:11 1-5, held by H. N. Harding's 45-horsepower English Daimler, was lowered to 1:59 2-5 for gasoline cars by J. B. Ryall, driving the 60-horsepower Matheson 1906 Vanderbilt Cup car; to 1:49 4-5 for steam cars, by Walter C. White's 30-horsepower White steamer; and to 1:40 flat for motorcycles, by "Bill" Wray and his 6-horsepower Simplex-Peugeot.

In the event for cars costing over \$5,000, "Willie" Haupt drove his "Great Chadwick 6" to a record of 2:07, as against the English Daimler's 2:11 1-5.

Last year's 2:27 record of the 50-horsepower Stevens-Duryea, driven by S. H. Hancock, was simply smothered by the Great Chadwick, which cut the figures to 2:02 2-5.

J. P. Hardy, in a 25-horsepower Pope-Hartford, knocked 1:12 2-5 off Herbert Bitner's 35-horsepower Rambler record of 3:18 1-5 for cars costing \$4,000 and under when he negotiated the course in 2:05 4-5.

C. W. Hoffman piloted a 30-horsepower Stearns upwards in 2:16 4-5, capturing the event for stock touring cars of all prices and horsepower and completely equipped. In the event for Quaker

City members Hoffman made the ascent in even better time, his figures being 2:13 2-5.

Charlie Soules' record of 2:56 4-5 for cars costing \$2,500 and under, made in a 24-horsepower Pope-Toledo, was lowered to 2:31 3-5 by Guy Hutchinson in a 24-horsepower Corbin.

The record of 2:47 for stock cars costing \$1,000 and under, held by H. J. Koehler in a 22-horsepower Buick, was cut to 2:47 by the 22-horsepower Maxwell, driven by H. A. Grant.

While the improvements made in the course accounts in some measure for the fast time in all the events, the vast improvement in cars and drivers since last year is responsible in great part for the betterment. The Wilkes-Barre Automobile Club spent nearly \$500 in eliminating "thank-you-ma'ams" and widening and banking the road at the "Devil's Elbow" and on the ticklish "S" turn at the Mountain House, while the installation of the electric timing apparatus and the policing of the course cost as much more. But the club's enterprise was well repaid, for the Giant's Despair hill-climb, as a result of to-day's contests, has become the premier fixture of the kind in this country.

But One Discordant Note in Affair.

There was but one discordant note in the management of the affair, and that was the dispute which arose over the barring of steam cars from the free-for-all. It appears that Mr. White had made up his mind some time ago to send several cars to compete in the climb. The entry blanks sent out by the committee, aside from the usual price restrictions, contained no intimation that steamers would be placed in a separate class. Indeed, Mr. White

RYALL'S MATHESON RECORD HOLDER GETS A BOUQUET

C. W. HOFFMAN AND L. D. BERGER'S WINNING STEARNS.

THE LITTLE POPE-HARTFORD ON ITS EYE-OPENING RUN.

avers that the barring of his machines was not decided upon until he had arrived in the city, had had several trials upon the hill and had made it evident that they could cover the ground a trifle faster than the gasolines. Mr. White's contention is borne out in part by a letter, which reached him less than 24 hours before the starting of the first event and which, he declares, was the first official notification he had had of the barring of his entries:

WILKES-BARRE AUTOMOBILE CLUB,
Wilkes-Barre, Pa., May 29, 1907.

WALTER C. WHITE, ESQ.,
Wilkes-Barre, Pa.

My dear Mr. White:—Concerning my conversation with you of yesterday in regard to your entries of White steamers, I am sorry that your entry, being received so late, made it impossible for us to notify you that steam cars had been barred from participation in all gasoline automobile events in the contest to be held May 30th.

This conclusion was reached only after it was found that a large number of gasoline entries could not be received were steam cars allowed to compete in the gasoline events, and, inasmuch as up to that time, May 22, and in fact until May 27, no steam car entries had been received, the Contest Committee could see no other way to accomplish the greatest success of the Meet than to admit the large number of gasoline entries by excluding the steam cars, which is a privilege reserved the committee by the wording of the entry blank, namely, "The right to accept or reject entries is reserved."

However, the club is not indifferent to the fact that you are here with your cars, and that other cars may be here, and to that end has phoned the Quaker City Motor Club to inquire if they will permit steam cars in their classes Nos. 2 and 3, and the writer is advised in the affirmative, understanding, however, that such entries must be made by members of the Quaker City Motor Club. Also, the Contest Committee has added an 11th event to the program for steam cars, offering gold, silver and bronze medals for the winners of first, second and third places, respectively. This event, with a few Quaker City events, offers 10 prizes which are available to be won by steam cars.

If you are agreeable to having your entries transferred to the classes in which the same will be allowed, kindly advise us to that

STRIPPED MAXWELL THAT CLIMBED THE HILL IN 2:47.

effect immediately. We return herewith your original entries and cash deposits which accompanied the same, and also new blanks for you to fill out if the classes may meet with your approval.

Yours truly,
(Signed) P. A. MEIXEL, President.
C.

Mr. White is nothing if not a fighter, and, seeking out the newspaper men at the Franklin Club and the Sterling Hotel, he handed out the following statement:

"Some days ago entry blanks were sent me by the committee and I decided to enter in the free-for-all and in the Quaker City run-about class. I shipped my cars from Cleveland, arriving with them on Monday. I met a member of the committee, and, after a general discussion regarding the contest, filled out the entry blanks and turned them over to him. I then went to the hill and tried out my cars with very satisfactory results. When I returned to my hotel, late in the evening, I learned that Mr. Matheson had tried to get me on the telephone. Tuesday morning, when I went out for practice, several people told me that I was to be barred. These reports, at first incredible, were so persistent that I finally sought out the

SIXTY-HORSEPOWER THOMAS MAKING THINGS HUM.

president of the club, and through him met Mr. Matheson. Mr. Matheson told me that, at a meeting of the committee held last Wednesday night, steam cars had been barred from competing with the gasoline cars. He said that the committee could not get entries of gasoline cars unless this step was taken. I asked why no an-

TAKING DEVIL'S ELBOW AT HIGH SPEED IN A DRAGON.

nouncement of this ruling was ever made or why I had not been previously notified. I am still awaiting the answer.

"I am informed that the Quaker City Motor Club was communicated with, and, with characteristic sportsmanship, said they could see no reason why I should not compete in their event. So I suppose I am all right as regards this event, although, as a matter of fact, the committee has returned to me all of my entry fees. The official program, issued to-day, omits my entry from the free-for-all and inserts it in a class for steam cars which was not even mentioned in the original entry blanks and which I had in no way intimated that I would enter. I have supposed, as has everyone else, that every car which came within the proper price limitations or fulfilled other conditions which were expressly stated, could enter the several classes. Last year, when one of our cars (of much less power) competed, no question was raised regarding its eligibility.

"Who ever heard of barring any car from a free-for-all event? This meet is supposed to be held under American Automobile Association rules, which recognize no distinction as to motive power. In face of all these considerations, to say nothing of the fundamental principle of sport, 'May the best win,' the committee can urge in justification of their action 'only the stereotyped clause that they may 'reject all entries.'

"Furthermore, an over-night change has been made in the conditions governing the award of the Board of Trade cup. While it was formerly to go to the car making the best time, it now appears that my cars are barred from competing for this cup. Where do I stand?"

The committee refused to reverse its action, and yesterday the free-for-all was run off without the steamers, and as Mr. White refused to allow his cars to start in the special steam class in which, he said, they had been entered by the committee without his authority, the latter allowed him a time trial for each of his two cars—the "18" and the "30." The first resulted in a fizzle, its gasoline overflowing and catching fire near the top of the mountain, necessitating a stop and a hurried pushing of the car up to the finish to get it out of the way of the next contestant.

But Mr. White came back strong later in the day, when the second trial resulted in the establishment of a course record of 1:49 4-5 for automobiles, beating the best gasoline time, the Matheson's 1:59 2-5, by nearly ten seconds. Mr. White has an-

THE CORBIN WINNING THE EVENT IN ITS CLASS.

E [COMING OF THE RAMBLER ON A STRAIGHT STRETCH.

nounced his intention of protesting to the A. A. A. Racing Board against his exclusion from the free-for-all, and will ask that the first prize in that event be awarded to him in view of the fact that his car made the best time of the day.

SPEED OF THE STODDARD-DAYTON ON THE STIFF GRADE.

The Contest Committee of the Quaker City Motor Club fully explained its refusal to allow Mr. White to start his cars in its events by referring to a decision made before leaving Philadelphia that only those cars which were driven up from the Quaker City in the club run of that organization would be eligible. This explanation was satisfactory, especially in view of the fact that a Stanley runabout owned and entered by D. Walter Harper, a member, won the Quaker City runabout event in the very fast time of 1:56 4-5.

Surprises Sprung on the Wiseacres.

There were several surprises sprung on the wiseacres, one of them—two of them, in fact—being the winning of both the stock-car-under-\$5,500 and the stock-car-over-\$5,000 events by H. B. Larzelere's 50-horsepower Great Chadwick "6," driven by "Billy" Haupt. In the first-named event the Chadwick climbed to the finish in 2:02 2-5, the gasoline record up to that time and only 2 3-5 seconds slower than the final best figures of the Mathe-

son Vanderbilt car. In the over-\$5,000 event the Chadwick beat out two Mathesons and a Fiat with a run in 2:07.

In the race of the day, the free-for-all, the Chadwick was beaten out by the "60" Matheson, driven by J. B. Ryall, and the "60" Thomas Flyer, driven by M. Roberts, which latter car it had previously beaten in the \$5,500-and-under class. Four of the eight starters in the free-for-all beat the course record of 2:11 1-5—the Matheson, 1:59 2-5; the Thomas Flyer, 2:01 1-5; the Chadwick, 2:05 3-5, and the 25 Pope-Hartford, 2:06 4-5. The performance of the latter car was another surprise. Its comparatively low power put it in the long-shot class but it performed consistently in all the events in which it started. Its win of the \$4,000-and-under class in 2:05 4-5, beating out such veterans as the Thomas 60, the Rambler 35-40, the Oldsmobile 35-40, and the Pennsylvania 35, gave the first intimation of its stability as a hill climber and its triumphs were hailed as a great victory by the "valves-in-the-head" advocates.

One wonderful performance which should be noted was that of "Bill" Wray and his 6-horsepower Simplex-Peugeot motorcycle. THE AUTOMOBILE representative was at the "Devil's Elbow" when Wray made his 1:40 trial, and saw a specimen of dare-devil work which has probably never been excelled in this country. Climbing up the hill at full speed, he took the turn, which is many degrees less than a right angle, without an appreciable let-up, and sped on up and out of sight as a great sigh of relief rose from the more than 10,000 people who had selected that point of the course as the best place to witness possible accidents. The committee had prepared for any emergency of the kind, and had installed an ambulance and temporary hospital at the Mountain House, but, fortunately, they were not called upon.

Apart from the White steamer incident the affair was run off with a promptness and lack of friction which argues well for the

CHADWICK "GREAT SIX" THAT GATHERED IN HONORS.

thoroughness of the preparations. It was no child's play to pull off more than 60 trials in six hours, and keep the course clear and prevent mix-ups. Allowing five minutes to each trial, and keeping all the contestants in each event at the top of the mountain until that event was finished, there were absolutely no delays, and the 30,000 spectators who lined the course had something to keep them busy all the time. Winners and second and third place cars were given blue, red, and white flags as they came down the mountain. Announcements of results and of the next car to essay to climb were made not alone at the start and finish, but at the Elbow, the Mountain House, and at Prospect Rock, so that all along the 6,000-foot route up the mountain the crowds knew just what was going on all the time. Press men and officials were given free access to the course, but at all the points where the crowds congregated the thickest policemen, armed with red flags, kept the people behind the ropes. The officials at the start were congregated on the porch of a little house in the village of Laurel Run, at the foot of the mountain. At the other official stations small wooden stands had been built, all connected by telephone. At the conclusion of the races the management slipped up, not having made any provision for carrying the officials back to their hotels. The latter were equal to the occasion, however, and, pre-empting a water-wagon, were driven triumphantly back to town the observed of all observers.

The winner of the runabout class in the recent Harrisburg endurance run the 30-35 Stoddard-Dayton of E. L. Leinbach, competed in two events and landed one third. The Autocar which won last week's 24-hour Quaker City Derby also took part in a couple of races, but failed to score. The Dragon and the Mitchell which finished fourth and fifth in the twice-round-the-clock event were also there, but failed to bring back a trophy. None of these four cars, however, had been specially tuned up for the climb, all having their usual stock gears and going into the several events in the trim in which they were driven up from Philadelphia.

The success of the Giant's Despair climb was such that the officials of the Wilkes-Barre Automobile Club are positive that the event will become an annual fixture. Although the club is put to considerable expense in preparing the course and returning it to its original shape and although the receipts do not begin to approximate the expenditure, the officials are prepared to run the event annually as an advertisement for their town and their club. As an earnest of their good faith in this matter, they point to many miles of improved roads in and around Wilkes-Barre, not to mention the signboarding of the roads leading into the city. The money of the club and of its individual members has in great part paid for these improvements.

The Summary of the Events.

TIME TRIAL FOR COURSE RECORD (2:11 1-5, HELD BY ENGLISH DAIMLER).

White, 30-h.p.; driver, Walter C. White.....1:49 4-5

FREE-FOR-ALL, STRIPPED AND RACING CARS.

1. Matheson, 60-h.p.; driver, J. B. Ryall.....1:59 2-5

3. Indian, 4-h.p.; driver, Jos. McLaughlin.....2:18

AUTO TERRORS HAVE RACES OF THEIR OWN.

Any automobilist who wished to have the pleasurable sensation of seeing a "motor-bike cop" coming toward him at full tilt without visions of a subsequent visit to the police court and its attendant fine could have enjoyed himself to the limit last Saturday at the Empire City race track. There were several score of them there and they discovered that the coppers are good for thirty-five miles an hour without trouble, while Commissioner Bingham also learned things regarding the abilities of this part of the force under his command.

The most interesting event of the day was a fifteen-mile race in which six competitors took part. Patrolmen John Dillon, of the Bronx, and Arthur Innes, of Brooklyn, were alternate favorites for six miles, the latter finally crossing the tape fifty feet ahead of his hanger-on patrolman, S. W. Johnston, of Brooklyn, being a close third. In the first mile of this race the forks of Sergeant McDonald's machine broke, but he escaped injury. The redoubtable Sergeant Casey, whose prowess in this field gave

TWO OF NEW YORK CITY'S NOTABLE "BIKE" COPS.

Sergeant Eugene Casey and Acting Sergeant Benjamin Mallam, recipients of the Automobile Club of America honor medals.

rise to the name "the terror of autoists," was not in good fettle. He entered two races, but was not even placed. Sergeant Anthony Howe was the star of the meet, winning the mile championship in 1:39, the ten-mile handicap from scratch, the five-mile open, the obstacle race, and he was also a member of the winning team in the pursuit race contested for by a New York and a Brooklyn team, Sergeant Mallam being his partner. With the exception of the latter's machine, which was a twin-cylinder Indian, all machines were single-cylinder models of same make.

Special policeman Winthrop E. Scarritt and expert timer S. M. Butler of the A. C. A. were the officers of the meet.

OLDSMOBILE WINS TWICE AT BAY STATE MEET

By C. F. MARDEN.

BOSTON, May 30.—This was Oldsmobile day at the Readville race track, where the Bay State Automobile Association held its annual meet. There were only two events, one at 100 miles for stock touring cars and the other at 50 miles for stock runabouts, and the Oldsmobiles entered by the A. E. Morrison

FALBERTH AND OLDSMOBILE THAT WON THE 100-MILE.

Company won both, establishing a new world's record of 2 hours 10 minutes 30 seconds in the touring car race, and covering the fifty miles in 1 hour 3 minutes 24 seconds, which is also thought to be a record. William Falberth drove the touring car, which went the distance without a falter, reeling off mile after mile as regularly as clock-work. Fred Allen, of Boston, drove the runabout, and its performance was no less consistent than that of the touring car. The two Oldsmobiles were of 35 horsepower, equipped with Diamond flat-tread quick-detachable tires, and it was unnecessary to change a single tire from start to finish.

In the touring car race a 30-horsepower Cadillac, driven by Harry Murch, was second, and a 50-horsepower Frayer-Miller, driven by Fred A. Lewis, the local manager, was third. In the runabout race a 40-horsepower American, driven by W. A. Frederick, won second place, while a Royal Tourist, with Harold D. Church at the wheel, was in third place. There were eight starters in the 100-miles event and eleven in the runabout class, all being gasoline cars with one exception, a steam runabout of 25-horsepower, driven by Bert Holland.

The day was ideal for racing and the track was in the very best of condition. The track had been rolled smooth, and was so thoroughly oiled that the cars, spinning around mile after mile, failed to raise any dust. This gave the spectators a fine view of the races, and despite their length the crowd of over 5,000 people kept up interest throughout the afternoon. Not a single accident marred the day's sport.

At the beginning of this event the 40-45-horsepower Jackson had jumped into the lead, closely pursued by the Oldsmobile and the American. Robert Burnham was at the wheel, and by skillful driving and a remarkable show of speed he succeeded in lapping his nearest competitor in the first twenty-five miles. Holland had been unable to get his Stanley going well at the beginning, but when he was about twenty miles and the Jackson at twenty-five or six, the steamer got into shape, and Holland started out to make up for lost time. He took the Jackson for a pacemaker, and after chasing it for several miles eventually got ahead. Then it was nip and tuck, mile after mile, not more than fifty feet separating the two cars at any time.

A. E. Morrison, besides his Oldsmobile entries, had a Stearns

30-horsepower stripped touring car in the 100-miles race, which he drove himself. At the very start he gained the lead, and by cutting out a terrific pace succeeded in gaining regularly every lap until, at thirty miles, he had a lap or two on the Oldsmobile and the Cadillac. His driving was one of the best exhibitions of the day, and he was looked upon as an almost certain winner. In attempting to pass two cars on the lower turn, however, one of his tires flew off. He completed the lap, however, replaced the tire and was again in the race, having third place at thirty-five miles. His luck was against him, however, for he had more trouble, and though he kept at it he had to make frequent stops and eventually finished sixth. Harry Murch drove a heady race with his Cadillac, rarely varying the speed from round to round. The Dragon, driven by John Liffike, of the Dragon Automobile Company, and the Grout, driven by K. A. Grout, kept on very even terms mile for mile but the Grout won fourth place and the Dragon fifth. The 20-24-horsepower Jackson was seventh and the Moon was eighth. The position of the Moon was due to bad luck, as Neilsen drove a fine race. Summaries:

One Hundred-Mile Race for Stock Touring Cars.

Place	Car	Driver	H.P.	Time
1	Oldsmobile	W. Falberth	35	2:10:30
2	Cadillac	H. Murch	30	2:16:55 1-5
3	Frayer-Miller	F. A. Lewis	50	2:38:30 1-5
4	Grout	K. A. Grout	35	
5	Dragon	J. Liffike	24	
6	Stearns	A. E. Morrison	30	
7	Jackson	E. P. Blake	20-24	
8	Moon	V. A. Neilsen	30-35	

The times of the winning car at intermediate distances were: 25 miles, 32:10 2-5; 50 miles, 1:05:09 2-5; 75 miles, 1:37:48 4-5; 85 miles, 1:50:55 1-5.

Fifty-Mile Race for Stock Runabouts.

Place	Car	Driver	H.P.	Time
1	Oldsmobile	Fred Allen	35	1:03:24
2	American	W. A. Frederick	40	1:04:45 1-5
3	Royal Tourist	H. D. Church	40	1:08:52 1-5
4	Stanley	Bert Holland	25	
5	Jackson	Robert Burnham	40-45	
6	Corbin	J. W. Swan	24	
7	Grout	C. B. Grout	35	
8	Crawford	G. M. Wetherbee	45	
9	Knox	A. E. Dennison	30	
10	Dragon	E. O'Donnell	24	
11	Logan	E. P. Blake		

The times of the winning car at intermediate distances were: 5 miles, 6:48; 10 miles, 13:08 2-5; 15 miles, 19:35 3-5; 20 miles, 25:49 1-5; 25 miles, 32:04; 30 miles, 38:07 2-5; 35 miles, 44:28; 40 miles, 50:58 2-5; 45 miles, 57:09 4-5.

FRED ALLEN AND HIS WINNING OLDSMOBILE RUNABOUT.

GRAND LINE-UP OF THE OLD AND NEW, FAST AND SLOW, OF THE OLDSMOBILE CLAN AT EMPIRE CITY CRACK.

OLDSMOBILERS GET TOGETHER AND CELEBRATE

If one had found himself put down unexpectedly at the vicinity of Fifty-second street and Broadway on Memorial Day morning he would certainly have gained a strong impression that all the automobiles in New York were Oldsmobiles. There were Oldsmobiles here, there and everywhere—the entire neighborhood was preempted by Oldsmobiles of all vintages and they kept coming steadily, until when the time for the parade to the Empire City track came to start there were some 300 of them to fall in line. It was Oldsmobile day, the only event on the program not participated in by the Oldsmobilers themselves being an exhibition 15-mile drive by Cadrino in the Fiat, Jr., in which he succeeded in lowering his previous record by a substantial margin. The Italian did every one of the fifteen miles under the 60 second mark and established new world's records for 10 and 15 miles by a medium weight car on a circular track. The 10-mile mark was passed in 9:47 1-5 and the total distance was covered in 14:45. The previous records for both distances were held by Bernin in a Renault.

Among the regular events on the program, an Australian pursuit race easily carried off all the honors in point of interest. It was also dubbed the Hare and Hounds race and consisted of starting four cars at the quarter mile posts, the winner to be he who first passed the other three contestants—the old unlimited pursuit race of bicycling days. D. Bruce Brown started from the tape, C. L. Waterbury at the first quarter pole, J. Augustine at the half mile, and Dr. J. P. Thomas at the three-quarter. Augustine was eliminated by Waterbury at the end of 2 1-4 miles, the next to drop by the wayside being Dr. Thomas, who was passed by both the remaining contestants simultaneously after he had completed 5 1-2 miles. Waterbury held out gamely for three-quarters of a mile further and Brown's efforts to get by him aroused a great deal of interest, finally succeeding right in front of the stand and just before completing the seventh mile. Time, 7:36 4-5.

Honors in the one-mile race for curved dash runabouts were carried off by John W. Colby, of Norwalk, Conn., in 2:42 2-5; J. J. Durand and Fred Holbrook, both of New York City, coming along in the order named. The two-mile event for 1906 roadsters was won in 2:47 1-5 by C. Allan Hudson, of Westbury, Long Island, with L. R. Adams, of the Long Island Automobile Club, second. After making a false start and being compelled to come back to the line, Oliver Light, of Dobbs Ferry, overcame this ill omen and captured the mile race for 1906 touring cars in 1:35 4-5; J. H. Walsh, Elmhurst, Long Island, was second, and J. J. Durand third. L. E. Bamberger, of New York, took the two-mile race for 1907 touring cars in 3:20 1-5; Tunis Speare and Allan Hudson, both New Yorkers also, coming in second and

third. The last event on the large car program was a three-mile event for 1907 roadsters. It was won by D. Bruce Brown in 3:48 2-5, with C. L. Waterbury second, and F. G. Schmidt third.

Something that promised to be of considerable interest was the "progress race" between a 1903 curved dash runabout of the single-cylinder type and a 1907 roadster, the former being driven by a diminutive youth of the name of Edward Steurwald, while the roadster was piloted by Tunis Speare. According to the program, the new car had to make two laps to the ancient one's single time round, but evidently no one had made very painstaking calculations as to their relative ability, for the arrangement fell short by half, the new car completing two miles in 2:51, while the veteran required 5:15 to do the same distance, or about four laps to one.

The crowning event of the day was the drawing for a 1907 Oldsmobile; there were some 300 numbers to be drawn, each owner being entitled to an opportunity to test his luck. The good fortune fell to Lindsley Tappin, a young New York stock broker, who chose an Oldsmobile roadster as his prize. The other prizes consisted of silver cups, and as arrayed along the fence by the host of the day, Gen. John T. Cutting, made an impressive showing. They were awarded as fast as the events were run off.

The summaries follow:

ONE MILE, SINGLE CYLINDER RUNABOUTS.

1. John W. Colby, Norwalk, Conn.....2:42 4-5
2. J. J. Durand.
3. Fred Holbrook.

TWO MILES, 1906 ROADSTERS.

1. C. Allen Hudson.....2:47 1-5
2. J. R. Adams.

ONE MILE, 1906 TOURING CARS.

1. Owner, H. T. Clinton; driver, Oliver Leighton.....1:35 4-5
2. John H. Walsh.
3. J. J. Durand.

TWO MILES, 1907 TOURING CARS.

1. Owner, L. E. Bamberger; driver, G. S. Richardson.....3:20 1-5
2. C. Allen Hudson.
3. Tunis Speare.

THREE MILES, 1907 ROADSTERS.

1. D. Bruce Brown.....3:48 2-5
2. C. Allen Waterbury.
3. F. G. Schmidt.

FIFTEEN-MILE EXHIBITION AGAINST MIDDLEWEIGHT CAR RECORDS BY CEDRINO, DRIVING 24-HORSEPOWER FIAT JUNIOR.

One mile, 0:59 3-5; 2 miles, 1:57 4-5; 3 miles, 2:57 2-5; 4 miles, 3:56 1-5; 5 miles, 4:54 4-5; 6 miles, 5:53 1-5; 7 miles, 6:52; 8 miles, 7:50 3-5; 9 miles, 8:48 2-5; 10 miles, 9:47 1-5; 11 miles, 10:46; 12 miles, 11:45 2-5; 13 miles, 12:44 1-5; 14 miles, 13:44 2-5; 15 miles, 14:45. New records established from 10 to 15 miles inclusive.

HARE AND HOUND RACE, FOUR STARTERS AT ONE-QUARTER-MILE DISTANCES, WINNER TO BE FIRST TO PASS THREE CARS.

1. D. Bruce Brown in .6 miles.....7:36 4-5
2. C. L. Waterbury.
3. Dr. Julian P. Thomas.

HOW THEY CLIMBED THE HILL AT BRIDGEPORT

BRIDGEPORT, CONN., June 3.—With Joe Tracy as a drawing card, the success of the Bridgeport Automobile Club's hill climb at Sport Hill, Easton, last Thursday, was assured. The weather gods were propitious and interest in the event did the rest, so there was nothing left to be desired; the spectators lined the entire course many deep at all points. The contest was in charge of A. L. Riker as referee, who managed the affair superbly, while the arrangements worked out by Chairman Ralph M. Sperry and his committee made things go like clockwork.

The Stanley steamer carried off the honors by making the distance in 1:24 2-5, with a big Stearns as next best in 1:25 flat. Tracy had originally been down to drive the Locomobile as a contestant, but Mr. Riker, not considering that the entry and his position as referee were consistent, decided to withdraw the car, so that the latter was merely sent over the course against time, the result being a tie with the Stanley. Most of the spectators and club officials were confident that Tracy could pilot the Locomobile over the course in better time and urged Mr. Riker to consent to a second trial, which was not granted.

The hill is characterized by a nasty S turn at the top and on this some came to grief. A Pope-Hartford car with H. P. Seymour, assistant superintendent of the Pope factory, at the wheel suffered the most severely, but strange to say, this accident occurred on the only straight stretch of the course and in plain view of the judge's stand. Seymour was going at a terrific clip and had the best time of the day beaten by at least fifteen seconds, when he lost control as the result of the car's jumping into the air in crossing a gully. It leaped the ditch, barked a big maple, skinned a second and made its finale at the inevitable telegraph pole. Seymour was thrown some distance, but was only slightly dazed. The only other accident of the day happened to W. Irvine Fickling's Stearns, which bore the magic number 23. It got away from the start in a manner that befitted its entry numeral, but came to grief a short distance up the road, with two bursted tires on the front wheels. The axle and front wheels of the car were removed and those of Mr. Fickling's touring Stearns substituted, the car subsequently making the distance against time and doing it in 1:25 or but 3-5 of a second off the day's record.

The day's program consisted of five events for the different classes of cars and one for motorcycles. A silver cup was put up

for each event, that in class one being captured by a 12-horsepower Maxwell, driven by Mr. Watson, of Pawtucket, R. I. He was the first starter of the day and covered the course in 2:06. Ralph Sperry, driving a 15-horsepower Ford, was the only other entrant and did it in 2:18. This was for cars under \$1,000.

In the second class Harry D. Gates, of the Fairfield Auto Company, captured the prize in a 12-horsepower Reo.

The third class for cars from \$2,000 to \$3,000 brought the record down to 1:40, which was made by Herbert Seymour in a 30-horsepower Pope-Hartford.

Class four was without limit above the minimum of \$3,000 and provided more interest than its predecessors. The honors were taken by Nat Bishop's 50-horsepower Simplex, with John Woods at the wheel, crossing the line in 1:37 3-5, while T. W. Pearsall's Packard 30 did it in 1:41 3-5.

The free for all was the real event of the day, a Thomas leading off with a performance of 1:30 1-5; the Stearns came next, but butted the bank, then the little Stanley cleared the field by roming over the line in 1:24 2-5. The summaries:

CLASS ONE.—STOCK CARS COSTING \$1,000 OR LESS.

1. Maxwell, 12-h.p.; driver, Mr. Watson.....2:06
2. Ford, 15-h.p.; driver, Ralph Sperry.....2:18

CLASS TWO.—STOCK CARS COSTING \$1,000 TO \$2,000.

1. Reo, 16-h.p.; driver, Harry D. Gates.....2:19
2. Reo, 16-h.p.; driver.....2:27
3. Jackson, 20-h.p.; driver, Arthur W. Bell.....2:30

CLASS THREE.—STOCK CARS COSTING \$2,000 TO \$3,000.

1. Pope-Hartford, 30-h.p.; driver, Herbert Seymour.....1:49
2. Oldsmobile, 40-h.p.; driver, Mr. Lyford.....2:12
3. Continental, 30-h.p.; driver, Mr. Johnson.....2:12

CLASS FOUR.—STOCK CARS COSTING OVER \$3,000.

1. Simplex, 50-h.p.; driver, John Woods.....1:37 3-5
2. Packard, 30-h.p.; driver.....1:41 3-5
3. Packard, 30-h.p.; driver, John Woods.....1:46

CLASS FIVE.—FREE-FOR-ALL AND RUNABOUTS TO \$6,000.

1. Stanley, 20-h.p.; driver, C. S. Bragg.....1:24 2-5
2. Locomobile, 40-h.p.; driver, Joe Tracy.....1:24 2-5
3. Thomas, 60-h.p.; driver, George Townsend.....1:30 1-5
4. Stevens-Duryea, 50-h.p.; driver, R. B. Crawford (protested).....1:32 3-5
5. Stearns, 60-h.p.; driver, W. I. Fickling (protested).....1:25
6. Oldsmobile, 40-h.p.; driver, J. W. Burrall.....1:36 2-5
7. Thomas, 40-h.p.; driver, Kenneth McNell.....1:46 1-2
8. Continental, 30-h.p.; driver, Mr. Johnson.....1:52 3-5
9. Thomas, 60-h.p.; driver, G. Townsend.....2:02
10. Oldsmobile, 40-h.p.; driver, F. W. Williams.....2:28 1-5
11. Berliet, 40-h.p.; driver, W. J. Morden.....1:51 1-2

CLASS SIX.—MOTORCYCLES.

1. Indlan, 2 1-4-h.p.; ridden by Peter H. Cox.....1:30
2. Curtiss, 5-h.p.; ridden by C. Edward Clark.....1:31 1-5

JOE TRACY CLIMBING SPORT HILL AT BRIDGEPORT, CONN., MEMORIAL DAY, IN HIS 40-HORSEPOWER LOCOMOBILE.

SECOND SECTION LEAVING THE CLUB HOUSE.

PRESIDENT CAVERLY AND SECRETARY MARK BLAZED THE WAY.

WASHINGTON, D. C., June 3.—Harpers Ferry, W. Va., was the objective point of the initial run of the year of the Automobile Club of Washington, held May 29-30. Numerically, and in every other way, it was the best run the club has ever had, and has caused many members who have been heretofore lukewarm on the touring proposition to become enthusiastic over the delights of touring. The future runs of the club, and a number of very interesting ones, have been planned, will doubtless bring out the full strength of the club.

The start was made on the afternoon of May 29 from the club's country home on the Brightwood road. President Caverly, in an Oldsmobile touring car, and Secretary Mark, in a Maxwell, blazed the way, and were followed in quick succession by the balance of the party. The route was out the Brightwood pike to Olney, where a sharp turn to the left was made. Ridgeville, about thirty-four miles out, was the first stop.

The roads were in excellent condition, barring the numerous waterbrakes that are encountered throughout the entire journey. The grand old woods of Maryland, the sloping hills, the pretty streams, the fertile lands, the prosperous farms and homesteads, the ancient landmarks that date back to the days of the Revolution, make this one of the most interesting routes leading out of Washington. At Ridgeville the tourists struck the National Pike, and from this point they followed the route to Harpers Ferry so ably described, pictorially and otherwise, by "Pathfinder," in the May 9 issue of THE AUTOMOBILE.

Harpers Ferry was reached at 6 o'clock, the seventy-three miles being covered in five hours, including stops made at Ridgeville and Frederick. The Hill Top House, one of the highest points above Harpers Ferry, cared for the party, Proprietor Loving leaving nothing undone that would add to the pleasures of the tourists. The homeward trip was begun on the afternoon of Decoration Day, the clubhouse being reached at dusk.

THOMAS "SIXTY" WINS BENNING'S "HUNDRED."

WASHINGTON, D. C., May 31.—Two automobile races and a motorcycle race comprised the program offered by the United States Motor Racing Association at the Benning's race track, Decoration Day. The principal event was the District Endurance Derby at 100 miles, open to touring cars and touring runabouts of 60-horsepower and under. It was won by W. C. Hood in a 60-horsepower Thomas in the fast time of 2:12:43. A. L. McCormick, driving a 35-40-horsepower Oldsmobile, was second, and J. A. Lutz, also in a 35-40-horsepower Oldsmobile, was third, their respective times being 2:22:11 and 2:26:38.

There were seven starters, the others being R. Mongini, 30-horsepower Columbia; Mrs. Cuneo, 45-horsepower Rainier; Howard Gill, Thomas "Forty," and Jack Conway, 50-horsepower Thomas. Hood took the lead from the start and was never headed, although Conway pushed him hard for fifty miles. The latter then began to have trouble, finally withdrawing at the end

of the seventy-sixth mile. Mrs. Cuneo, making her first appearance in Washington, created quite a sensation by her daring driving. She was in bad at the start, one of the four cylinders of her car being put out of commission before the end of the first mile. Tire troubles also caused her to make two stops, but she pluckily went the entire route. Mongini also finished, and made a hit with the crowd by his clever driving.

Hood also walked away with the other automobile event, which was at ten miles for the District championship. He drove the same car as in the 100-mile event and finished in 6:28, Jack Conway getting the place, with Howard Gill third. Mangol won the three-mile motorcycle race on an Indian; time, 4:11.

About four thousand people were present, but it is reported the promoters are not satisfied with the showing made in Washington, and will drop this city from the circuit. The weather was ideal, but there were many counter attractions that served to keep down the attendance.

MOTORCYCLISTS STORM MANHASSET HILL.

This year, in holding its fifth annual hill climb, the New York Motorcycle Club co-operated with the Brooklyn Motorcycle Club and the joint affair was held on Manhasset Hill, a twisting rise of stiff grades on the road between Manhasset and Great Neck, a short distance out on Long Island. Stanley T. Kellogg, of Springfield, Mass., whose name has always figured well up on the lists of the winners at every motorcycle meet, made a good attempt at maintaining his record in this respect by carrying off the first in the leading event for machines in Class 1, reaching the top of the hill on his 2¼-horsepower single-cylinder Indian in the good time of 1:14 4-5, while he took second in all the remaining events. The sharp turns of the hill proved too much for some of the riders, two of whom went down.

The winner in Class 2 was Albert Book, on a 4-horsepower twin-cylinder Curtiss, in 1:04 1-5, while G. H. Curtiss came in first in both Classes 3 and 4 on a 7-horsepower Curtiss in 0:55 and 0:56 1-5, respectively. The summaries follow:

CLASS I

1. Stanley T. Kellogg, 2 1/4-h.p. Indian..... 1:14 4-5
2. Percy J. Drummond, 2 1/4-h.p. Indian..... 1:15 2-5
3. B. S. Barrows, 1 3/4-h.p. Indian..... 1:19 2-5
4. George W. Holden, 1 3/4-h.p. Indian..... 1:21 2-5

CLASS II

1. Albert Book, 4-h.p. Curtiss..... 1:04 1-5
2. Stanley T. Kellogg, 2 1/4-h.p. Indian..... 1:17
3. Fred Littlefield, 4 1/2-h.p. F. N..... 1:17 4-5
4. George W. Holden, 1 3/4-h.p. Indian..... 1:18

CLASS III

1. G. H. Curtiss, 7-h.p. Curtiss..... 0:55
2. Stanley T. Kellogg, 4-h.p. Indian..... 0:59 4-5
3. Percy J. Drummond, 3 1/2-h.p. Indian..... 1:01 4-5
4. J. P. Bruyere, 7-h.p. Peugeot..... 1:09 1-5

CLASS IV

1. G. H. Curtiss, 7-h.p. Curtiss..... 0:56 2-5
2. Stanley T. Kellogg, 8-h.p. Indian..... 0:58 1-5
3. Albert Cook, 4-h.p. Curtiss..... 1:03
4. J. P. Bruyere, 7-h.p. Peugeot..... 1:10 2-5

AUTO RECOGNIZED AS A LEGITIMATE ENGINEERING STUDY

BY Charles B. Hayward

INDIANAPOLIS, IND., June 1.—For the first time in its history, the American Society of Mechanical Engineers has officially set its seal of approval on the automobile by recognizing the fact that it is a legitimate subject for engineering study. This means more than would appear at first sight, for in the history of the organization in question is written much of that of mechanical engineering as a whole in this country.

Wednesday was automobile day and the afternoon was devoted to visits of inspection. There was the alternative of taking in the plant of the Atlas Engine Works and with it that of the National Motor Vehicle Company, or of making a visit to the Nordyke & Marmon Company and another concern. A rising vote taken at the morning session was practically unanimous in favor of the former, and the engineers, three hundred strong, were toted out to the suburbs in special cars provided by the trolley service. The Atlas Engine Works are one of the oldest builders of steam engines and boilers on this side of the Atlantic, and in the widespreading plants, with hundreds of engines of all sizes in every stage of construction, the engineers found themselves in a familiar element. Though pioneers in the steam engine field and one of the large factors in it to-day, these builders have looked ahead and, recognizing the inevitable, have prepared for it. The gas engine department has already assumed large proportions and active preparations are now said to be under way, looking to the manufacture of automobile motors on a large scale. As has been its policy heretofore in the steam and gas engine field, nothing but the engines themselves will be built and they will be put through in quantities.

First Visit to an Automobile Factory.

From the Atlas works to the plant of the National Motor Vehicle Company is but a few minutes walk, and the engineers bent their steps in that direction with an eagerness born of curiosity, for they were about to enter upon what was to them an entirely novel field. The National people had taken this into account, for in addition to providing a liberal quantity of circus lemonade, they detailed several of their own engineering force to act as pilots and explain things. It was a pretty warm day and the pink lemonade was a welcome cooler after a trip through

a big foundry, but the "Explanationers" proved the most welcome bit of foresight on the part of the entertainers, for the visitors with few exceptions were like so many schoolboys when it came to things automobile. It was really more entertaining to watch the entertained than to try to take in the details of the plant itself. A group formed with a six-cylinder National chassis as its center was a point of interest to which I attached myself and was well rewarded. Its members had been admiring the compact and finely finished power plant concentrated in such a small amount of space and with no superfluous detail, when one of them—a big, husky fellow who looked as if he could have walked off with the engine under his arm without much difficulty—took occasion to ask what the power of the motor was.

"Seventy-five horsepower," replied the automobile engineer nonchalantly. "Seventy-five!" his interlocutor almost gasped. "But do you mean *brake horsepower*?" he came back, his look of incredulity reflected in the faces of the entire circle.

"Oh yes, they have to tune up better than that on the brake test in order to pass inspection. We have had them show as much as ninety horsepower on the brake for very short periods, but all of them exceed their nominal rating on test by at least ten to fifteen per cent."

With visions of the two or three tons of metal that represent the groundwork of a stationary engine of similar capacity in mind, the engineering contingent could only express its admiration and wonder in dumb amazement. Passing on through the various departments, chassis frames were felt and examined with many a headshake over the slightness of the metal forming their members, the gear and dashboard castings were toyed with, marveling at the great discrepancy between their bulk and avoirdupois like so many schoolboys.

Close Study Devoted to Details.

Next to the motors and the chassis in course of erection, which were probably the most unfamiliar objects, the details of the change speed gear and the rear axle unit came in for attention, for here at least was something more familiar though its application was a decided novelty. Here again the features of compactness, the ingenuity shown in design and operating methods

ONE OF THE INSTALLMENTS AT THE NATIONAL WORKS.

as well as the lavish use of the most expensive metals and jewel-like ball bearings called forth no end of admiration. They were at a disadvantage, these engineers. They had to let their guide talk without being able to do much talking back, for in all the interested groups I took in I only ran across one who could talk automobile through being the possessor of a car. Probably there were others, but for the most part the visit represented an initiation to the genesis of the automobile. The testing cars with their rough and ready fittings and the dynamometer rigged for testing the power output at the driving wheels of the completed car represented objects of unending interest.

Motors Under Test Proved Instructive.

As they finished their rounds of inspection of this part of the plant, the various installments were bundled into waiting cars and given a two or three-mile drive through the residential section of the city over to the motor-building department of the National works. The transportation of such a contingent naturally taxed the facilities of the plant to provide cars, and a Premier or two, with a Rambler, formed a scattering representation loaned for the occasion to help out. If anything, this part of the plant was more interesting than that in which the complete cars were assembled. Here the motors were to be seen at every stage in the process of construction, from the rough casting straight from the foundry to the complete motor on the testing block, and a dozen or more of the latter of both fours and sixes that were running full blast at the same time gave some idea of the rate at which they were being turned out. The center of attraction in the long testing room was the electric dynamometer with its water resistance to absorb the power developed. A four-cylinder motor was undergoing test at the time and the attendant in charge put it through its paces for the benefit of the visitors. The inspection completed to the satisfaction of all concerned, the roar of the testing plant was left behind for another ride in the cars back to the Claypool, giving an excellent opportunity to take in the fine four and a half mile oiled boulevard. Your Indianapolis chauffeur is a true representative of the genus—he lets her out whenever an opportunity offers, but he can pick up the scent of a mounted copper just as far away as any of his kind, and the discreet pace and solemn mien with which he passes the stern-visaged minion of the law are models of innocence and propriety, not but that the peeler has his own suspicions and he shows it, too, but he has to land the sinner "with the goods."

During the afternoon the "lady engineers" had not been forgotten, the same contingent of cars that was later impressed into service between the departments of the National works and as transportation back to the hotel were marshaled along the curb at the latter and used to carry bunches of fair femininity out

to the Indianapolis Country Club. When the ladies returned in the evening they were of one opinion that arrangements could not have been engineered more efficiently nor pleasantly, due to the energy and foresight of Mr. Wall, of the sales department of the National company, who was in charge of the automobile transportation arrangements for the whole contingent.

Papers Were of Absorbing Interest.

The Wednesday evening session was devoted to the reading of papers by engineers who have long been identified with the progress of the automobile. The papers presented were those on "Bearings," by Henry Hess, of the Hess-Bright Manufacturing Company; "Special Steels," by Thomas J. Fay, and "Materials for Automobile Work," by Elwood Haynes, of the Haynes Automobile Company, one of the deans of the American industry. Mr. Hess' paper was profusely illustrated with lantern slides, showing current types of gear-set construction and mounting as exemplified by the best in American and foreign practice, ball-bearing crankshafts of various types, and the like.

Mr. Fay's paper brought home for the first time to mechanical engineers who have only known the automobile as laymen the tremendous amount of work that has been concentrated on the study and production of special steels in a few years as the result of the widespread and pressing demand for automobile construction, while Mr. Haynes' lengthy experience in automobile building was reflected in his able outline of the subject of materials, dating as it does back to the time when the very commonest necessities of automobile construction were unknown and manufacturers had to turn out everything they needed down to the most rudimentary detail. All the papers proved of absorbing interest. John Wilkinson, of the H. H. Franklin Manufacturing Company, was down for a paper on the "Air-Cooling of Automobile Motors," and B. D. Gray, of the American Locomotive Works, for one on "Railway Motor Cars," but, unfortunately, neither was able to be present.

Of course, there were meetings and the like scheduled for Thursday, but an event that was not down on the program took the attention of the engineers in a body during the afternoon. President Roosevelt arrived in Indianapolis in the morning and after being escorted about by an imposing parade took part in the unveiling ceremony of the Lawton monument, and the engineers came early to listen to his speech. On Friday the whole contingent went to Purdue University at Lafayette, where the papers on superheated steam were read, points on superheated steam practise as exemplified in the White automobile being brought out in the discussion. An impromptu visit by some of the engineers to a nearby chicken factory was not on the program either and resulted in a learned discussion of the thermal efficiency of the incubator and brooder.

PRESIDENT ROOSEVELT "SPEECHIFYING" AT LAWTON MONUMENT.

AIR COOLING OF AUTOMOBILE ENGINES*

By JOHN WILKINSON, CHIEF ENGINEER. H. H. FRANKLIN MFG. CO.

THE result always first met by the investigator of the air-cooled engine for automobile work has been that the motor became too hot for proper operation, and therefore the problem has been to find out how overheating manifests itself and how to overcome the fault.

2. Overheating shows itself in quite a number of ways. The cylinder may become so hot that as a result the incoming gases expand so much that there is a reduction in power owing to the

FIG. 1.—A normal manograph card under full load.

smaller amount of air and gasoline taken in; the heat may be so high that the lubricating oil will fail to perform its proper functions, causing an increase of friction which still further heats the cylinder and reduces its power.

3. This has been proved by introducing such a lubricant as graphite, which is not influenced by heat, onto the cylinder walls after the power has dropped, and noting the almost instantaneous recovery of the power. The piston head may become expanded so much that it will seize. The incoming charge may become so heated by the walls and by compression that it is ignited prematurely.

4. This generally occurs at a low engine speed and is indicated by energetic knocking. Indicator cards taken by the monograph under these conditions show the pressure to have risen very much higher than normal, indicating that a true explosion may have taken place.

5. Fig. 1 represents an ordinary monograph card, and Fig. 2 shows the high initial pressure due to premature ignition from heat.

6. Again, some projection in the cylinder of metal or accumulated carbon, or more often a red-hot exhaust valve, may cause a premature explosion at high speed, or even a burning of the charge on entering the cylinder. This may also produce the same effect at low speed as is shown on Fig. 2. It is therefore necessary to apply such remedies as may obviate as much as possible the above conditions.

7. In order to keep the temperature of the cylinder walls within working limits, it is evident that the design must be such that either less heat must be allowed to enter the walls or more must be carried off, or both of these results must be accomplished.

8. Getting less heat into the walls involves one of the fundamental principles of the economy of the gas engine, and is best accomplished by reducing the internal surface exposed to combustion to a minimum which means principally to design the combustion chamber as nearly spherical as possible.

9. If the internal surface is less, the less the incoming charge is heated and the less heat is lost to the cylinder walls; therefore the greater the power and efficiency; the less heat it is necessary to carry off from the walls to keep them at a working temperature.

*Paper presented at the Indianapolis, Ind., meeting of the American Society of Mechanical Engineers.

This fact does not yet seem to be well recognized, and we still see engines built with a valve pocket on each side of the cylinder.

10. The internal surface exposed to heat at the time of explosion in a 4" x 4" motor with a semi-spherical cylinder head is about 38 square inches; in the same motor with a valve pocket on either side of the cylinder about 74 square inches, and a good part of this surface has to be left rough. It is self-evident that the jacket loss must be much greater in the last instance.

11. Engines with a semi-spherical head will show a gain of 25 per cent. in power and efficiency over the prevalent type with a valve pocket on each side. This type of cylinder head may also be machined smooth on the inside to reduce its absorbent effect to a minimum.

THE EXHAUST GASES.

12. In passing out of the cylinder these gases raise the temperature of the exhaust valve often to the point of premature ignition, and give up their heat to the metal adjacent to the valve and to the valve passages.

13. If a port is made at the bottom of the stroke, a large part of the exhaust will pass out here before the main exhaust opens, and the pressure will drop to atmosphere by the end of the stroke. Therefore, the temperature of the gases passing out at the exhaust valve will be greatly reduced.

14. The exhaust passages contiguous to the cylinder should also be made as short as possible.

15. Fig. 1 shows a manograph card taken from a 4" x 4 1-4" engine with an exhaust opening 40 degrees before the end of the stroke. Fig. 3 shows a card of a 4" x 4" engine, with auxiliary exhaust opening at the same point.

The best internal conditions may be summed up as follows:

- a To present the minimum internal surface to the heat.
- b To make this surface as smooth as possible.
- c To carry off the hot exhaust gases at the bottom of the stroke before the main exhaust valve opens.
- d To get rid of what is left with as little surface contact with the cylinder as possible.
- e To reduce the friction of piston on the cylinder to a minimum.
- f To keep all projections out of the cylinder.
- g To make the compression just right to fit all other conditions.

FIG. 2.—Premature ignition manograph card due to overheating of engine.

16. The above represents the science of air-cooling in regard to the internal conditions of the cylinder as far as the writer understands it.

17. There still remain the external conditions which, outside of the fact that the more circulation of air the better, have not yielded results that can so confidently be asserted as correct.

18. What the form, position, and material of the outside surface shall be has not been reduced to a positive science.

19. If we try to make the cooling surface part of the cylinder

casting, we meet great difficulties in the way of unsound casting, insufficient area, and too much weight. If we attach pieces of copper or other good conduction metal in the form of rings or studs, it is very necessary to take great care to make an extremely good mechanical joint. No one has yet succeeded in brazing or soldering such material to the cylinder in satisfactory form. An ideal cooling medium would be a finely and equally spaced growth of copper hair metallicity joined to the cylinder.

20. A still further complication of cooling is presented by the necessity of using a four-cylinder motor placed longitudinally in the car.

21. If it is attempted to cool this design by the general circulation of a fan in front, each cylinder tends to keep the air away from the next and to radiate its heat to its neighbor, and the cooling medium gets warmer as it gets toward the rear, decreasing its cooling power. It is therefore necessary to increase the cooling surface toward the rear of the engine; cylinder No. 3 requiring the most attention, and No. 2 requiring somewhat less, and No. 1 requiring very little surface, showing the efficiency of a rapid circulation on an unobstructed cylinder.

22. If we use a blower and drive the air separately over each cylinder, a large amount of power is absorbed by the blower, and a piping system of considerable complication is needed. It also has one of the weaknesses of the water-cooled motor, namely,

FIG. 3.—Manograph card showing effect of auxiliary exhaust openings.

the danger of ruining the motor by the breakdown of the circulating mechanism.

23. In regard to the size of the air-cooled motor that could be used in an automobile, an investigation of the relative sizes of the internal surfaces, volumes, and speeds of two similar engines seems to show that the larger the engine the lower the temperature of the cylinder walls. The only parts of a large engine that get hotter than a small one are the exhaust valve and center of piston.

24. If an auxiliary exhaust port is used, the exhaust valve gets no hotter than in a smaller engine, and therefore the limiting feature of air-cooling a large engine is the temperature of the piston center. I have used 4-cylinder engines as large as 5" x 5" with as much success as smaller ones.

25. In view of the above, it might be asked what can actually be said of the performance of air-cooled motors in practice. A 4-cylinder 4" x 4" motor with a clearance space of 26 per cent. of total volume delivering at the brake:

21 horsepower at 1,000 revolutions and

27 horsepower at 1,500 revolutions

or 1 horsepower for each 7.4 cubic inches of displacement at 1,000 feet per minimum piston speed will positively meet every condition of road use, and we hope to see in the near future 30 horsepower at 1,000 feet piston speed or 1 horsepower for each 6 2-3" piston displacement. This, so far as the writer knows, is as good as is commercially produced in a water-cooled engine of the same size and of the most efficient type.

26. As to the heat efficiency of a motor of this size, tests show it to be as high as 20 per cent., which represents 0.7 pounds of gasoline per brake horsepower hour.

27. In so much as the air-cooled motor we are talking about is meant to use only on a road vehicle, it must stand or fall on its merits as such. It would not be reasonable to assert that an engine can be kept as cool with air as with water, and it is not desirable to do so anyway, as the efficiency will be higher with the hot motor.

28. The air-cooled motor is correct in theory in that it directly cools by the air, and the ordinary type is simpler, lighter, cheaper and proof against extreme cold and extreme heat. In respect to its cooling it is not dependent for its safety on any working mechanism. Even with the loss of its fan it can generally be brought to its destination on schedule time. Such faults as it has had have been slowly eliminated. Whether it has any inherent defects which can never be corrected is very doubtful, and its entrance into even the high-powered field is only a question of time.

SOME FACTS CONCERNING ALUMINUM.

The great rise in the price of copper during the past year and a half, and the fact that the demand has exceeded the supplies of this metal, lends additional interest at the present moment to the position in the aluminum industry, says *The Engineer*. For aluminum is the one metal which may take the place of copper in many of the arts and industries, and the recent enormous increase in the demand for aluminum is probably connected with the high prices ruling in the copper market. It is noteworthy that this metal, which down to the year 1889 was produced only by chemical method, and was looked upon more or less as a curiosity, is now manufactured at the rate of 12,000 tons per year in works controlling over 96,000 horsepower, and that the output is rapidly increasing. Since the relative specific gravities of aluminum and copper are in round numbers in the ratio of 1:3, it follows that the annual output of aluminum at present is equivalent in volume to 36,000 tons of copper. Two of the larger companies producing the light metal are, however, arranging to double, or even treble, their water-power and reduction plants at an early date, and the production of aluminum in the year 1909 may quite possibly rise to 24,000 tons per annum, or to the equivalent in volume of 72,000 tons of copper. The possibility of aluminum or its alloys supplanting copper in many of its applications is, therefore, not so remote as many engineers might suppose, and the fact that in the form of oxide it is one of the commonest constituents of the earth's crust would seem to indicate that it will occupy a position of increasing importance in the metallurgy of the future. The most important factor in this increase will be a reduction in price due to cheapened methods of production. At the present time the ingot metal is selling for \$1,000 per ton, or at the rate of 43 cents per pound, and is the equivalent in volume of copper at \$335 per ton. Owing to the greater difficulty of working aluminum, and the necessity for using it for many purposes in the form of alloys, the practical difference in cost of the metals is less, however, than is indicated by these figures. There is good reason to suppose that aluminum can be produced, even now, at a cost of 24 cents per pound, or \$560 per ton. Should a simpler method of preparing the aluminum oxide for the electrolytic bath be discovered, this first cost may be reduced to 16 to 18 cents per pound, equivalent to \$375 or \$420 per ton.

WHERE ASBESTOS IS MINED.

Asbestos is mined in open pits similar to stone quarries, and, although it is found in all parts of the world, the mines in Quebec are the most famous, yielding about 85 per cent. of the world's supply of chrysotile. In 1879 the output of the Quebec mines was 300 tons, which has steadily increased year by year to 50,000 tons in 1905.

SOME FEATURES OF AUTOMOBILE CONSTRUCTION*

By THOS. J. FAY, E.E.

THE range of speeds on the 30-inch lathe was fixed the same as the speeds would be fixed for smaller lathes, for small work, and, in fact, the 20-inch lathes ran at the same speed as the 30-inch tools.

It was found that tool steel of almost every make would not stand up, but it was also found that the finer grades of nature-hard tool steel, as "Novo," "Bischoff" and "Krupp Quick Cutting"—air hardened—tool steel held up in a manner most becoming. In the experiment in question, Novo drills and cutters were found to pay for themselves; although, if prayers would reduce the price, one would be tempted to say, "Let us pray."

The color of the turnings from chrome nickel steel off the larger sizes of tools are always "blue"—a sample of which is available here for inspection,—and the best way, perhaps, to pay labor is by the color of the turnings; although a machinist on a 16-inch lathe, if paid by color, *would starve to death.*

In designing it would seem as if "lathe work" is by far the easiest of accomplishment, and "milling" is superior to "shaping." There are many pieces in a car that, if carefully looked over, can be more nearly finished on a lathe, and, as a rule, lathe accuracy is satisfactory, especially if "finishing" is done on a grinder subsequently.

As regards the question of the need for the finer grades of steel in motor car practice, everything depends upon the car and the service. A high-powered heavy car certainly will be superior, if perchance certain of its most important parts are alloy steel, and, too, it is believed, the extravagant use of fine steel is a *better* mistake to make, than to inflict a Bessemer steel crankshaft, for illustration, on an unsuspecting purchaser.

Springs have been a great source of annoyance to most every builder of cars, and it is now quite plain to be seen that the carbon steel railway springs of ancient vintage will not suffice, excepting for low-powered light runabouts.

A good and much-used railway spring formula is as follows:

SPRING STEEL

Carbon.....	0.80+
Silicon.....	0.12-
Sulphur.....	0.035-
Phosphorus.....	0.80-
Manganese.....	0.80-
Arsenic.....	0.12-
Copper.....	Trace

This grade of material is medium good, and serves for springs in places indicating the use of carbon steel. The average motor car indicates the use of alloy steel for springs, and a recent American alloy steel spring product promises to serve the purpose extremely well, the analyses of which, as now known, being as follows:

	I	II	III
Chromium.....	0.99	1.31	1.25
Nickel.....	1.17	1.65	2.00
Tungsten.....	1.02	1.31	1.00
Carbon.....	0.20	0.25	0.35
Silicon.....	0.037	0.056	0.23
Sulphur.....	0.017	0.011	0.041
Phosphorus.....	0.018	0.013	0.023
Manganese.....	0.23	0.12	0.17

These analyses show every indication of fine steel, and the reports thus far are of a far better tone than any of the carbon steel performances. The physical properties of this steel are about as follows:

T. S.	E. L.	Ex.-2"	Con.
155,000	150,200	16	47

which, for normal steel, is a very satisfactory condition.

Side frames are, as yet, a more or less unsatisfactory quantity,

* Paper read before the Society of Automobile Engineers. Continued from page 888, issue of May 30.

mostly because there is no standard, and changes are at once noticeable. Foreign cars, of the latest vintage, show very heavy side frames, with very wide flanges, largely for effect. Some of the best of the foreign side frames are of what is known as C 46-0 Krupp steel, the physical properties of which are given by "Krupp" as follows:

T. S.	E. L.	Ex.-2"	Con.
114,600	93,300	17	55

There is one excellent "French" product, but little used, however, as follows:

CHEMICAL COMPOSITION

Nickel	Carbon	Silicon	Sulphur	Phosphorus	Manganese
4½	.85	0.13	0.014	0.013	0.35

PHYSICAL PROPERTIES

T. S.	E. L.	Ex.-3.9"	Con.
121,000	108,000	14	42

In some American cars, as the B. L. M., and possibly others, as well as such of the cars as the speaker is now engaged upon for Mr. Ellsworth, the chassis frame stock is made of E. F. 60.0 Krupp chrome nickel steel, the normal properties of which are as follows:

CHEMICAL COMPOSITION

Chromium	Nickel	Carbon	Silicon	Sulphur	Phosphorus	Manganese
1.50	3.50	.25	.20	.025	.012	.40

The normal physical properties are as follows:

PHYSICAL PROPERTIES

T. S.	E. L.	Ex.-2"	Con.
110,000	95,000	20	44

It will be understood that rolled into sheets, this product increases in tensile strength and elastic limit enormously. As regards the hot and cold bending test, enough is to say, it will barely stand 180° and hammering down flat; in fact, some proof falls short of this exacting test.

One more product for side frames that has been used with good success is that known as Firebox Steel, as follows:

CHEMICAL COMPOSITION

Carbon	Silicon	Sulphur	Phosphorus	Manganese
.15	.10	.40	.04	.30 to .50

Carbon subject to change to give physical properties:

T. S.	E. L.	Ex.	Bend Test
52,000	32,000+	26+	180° and hammer down flat, without any sign of cracking, both hot, red and cold
to			
62,000			

In any case, chassis frames are entitled to far more consideration than they have been accorded, in some cases at any rate, and it is not believed that good steel will be likely to put the cost so high as not to be tolerated.

The question of ball bearings will no doubt be handled admirably by Mr. Hess, and the speaker desires only to bring out one point that may be of general interest aside from ball bearings. It is generally conceded that the quality of the material used in certain ball bearing races is something out of the ordinary, and while it has changed from time to time, yet even so it can be set down as a chrome-wolfram steel, and not a chrome nickel steel product. The most recent information on the subject of this remarkable grade of steel was received by the speaker from his assistant, Mr. Jos. Schaeffers—now in Germany—giving the main chemical contents as follows:

Chromium.....	1.5%	} Carbon probably between 0.20 and 0.30 per cent.
Wolfram.....	1.0%	
Copper.....	0.01%	
Nickel.....	None	

As to the presence of copper, it is by design; as to its real advantage, it is difficult to say. The normal physical properties of this steel may be put down as follows:

T. S.	E. L.	Ex.
160,000	156,500	16

While this product, when heat-treated, could reach to marvelous heights, as for illustration, "double the normal tensile strength," that this steel would serve admirably for certain other work, as piston pins, gears, and such other parts as are subject to high pressure and shock loads, should be a reasonable expectation. Unfortunately, however, it has been exceedingly difficult to procure this product, manufactured as it was for an exclusive trade, or better yet, in spite of an excluded would-be trade.

"If you want to get acid open hearth steel low in sulphur and phosphorus, it must be at the expense of good raw material, and I claim that the misfortune of the mill in that connection is our fortune, because if we specify acid open hearth steel, and limit the phosphorus and sulphur to a low point, we will have procured steel from good raw material. That is assuming we get what we ordered."

Aluminum for motor cases, gear boxes and like parts is scarcely better than it ever was, and it never was strong; in fact, a reasonable expectation from the strength point of view is a maximum at 16,000 pounds per square inch, and 9,000 pounds per square inch will be in imminent danger. The elastic limit of cast aluminum is not as a rule a reasonable quantity and the elongation is nominal.

In the *Horseless Age* of January 9, 1907, E. F. Lake reported the strength of aluminum castings as follows:

TEST NO. 1			
T. S.	E. L.	Ex.-4"	Con.
21,000	8,400	8.25%	9.5%
TEST NO. 2			
T. S.	E. L.	Ex.-4"	Con.
30,200	17,600	2.75%	5%

These values are utterly impossible of attainment in castings in a commercial way, if at all, nor do they accord in principle with the characteristics of aluminum castings; in fact, it is such tests that gave to aluminum a bad reputation, whereas, if designers will take into account its low strength, they can reduce weight by its use, but they can also court serious trouble by taking inflated values into account. The true strength of aluminum castings is reflected in the tests as follows:

"A"—CHEMICAL COMPOSITION			
Aluminum	Copper	Manganese	Iron
91.24	5.44	2.48	0.40
PHYSICAL PROPERTIES			
T. S.	E. L.	Ex.-8"	Con.
9,390	9,390	0.16	

Test proof 1 inch square. Test by Robt. W. Hunt & Co. for the writer:

"B"—CHEMICAL COMPOSITION			
Aluminum	Copper	Zinc	Iron
95.4	2.11	1.36	Trace
PHYSICAL PROPERTIES			
T. S.	E. L.	Ex.-8"	Con.
9,176	9,176	0.13	

Test proof 1 inch square. Test by Robt. W. Hunt & Co. for the writer. Motor case of this product broke in service.

Of all product testing higher, the foundry failed to make good castings, and it is doubtful if the foundry can. At the present time the foundry furnishing castings of aluminum for such work as the writer directs does so with the understanding that the tensile strength shall not be more than 16,000 pounds per square inch, and it is doubtful if this value is reached.

Manganese bronze is, of course, superior for such work, but it weighs more. The strength of this product is within the limits as follows:

MANGANESE BRONZE—PHYSICAL PROPERTIES			
T. S.	E. L.	Ex.-2"	Con.
65,000	30,000	20	25
75,000	35,000	25	30

The relation of weights is given by Lake as follows:

SPECIFIC GRAVITY	
Cast aluminum.....	2.85
Cast iron.....	7.218
Steel castings.....	7.919
Cast brass.....	8.320
Cast bronze.....	8.832

These figures will serve as a guide in estimating the advantages of aluminum from the weight point of view, but:

$$\frac{8.832}{2.85} = 3.098 \text{ ratio of weight in favor of aluminum;}$$

on the other hand, the ratio of strength would be approximately

$$\frac{70,000}{10,000} = 7 \text{ to } 1 \text{ in favor of bronze,}$$

and the ratio of cost would be:

$$\frac{65}{32.5} = 2 \text{ to } 1 \text{ in favor of bronze.}$$

Result: Three hundred and nine pounds of bronze would do the work of 700 pounds of aluminum, with equal liability to rupture, making the section in the ratio of one to seven, and the cost \$100.42 for bronze and \$445 for aluminum, although it is fair to say it is rarely possible to make the section of bronze so much thinner than aluminum, nor would one care to do so, since greater strength than aluminum affords is much to be desired. Nevertheless, 'tis well to know the lay of the land.

WHY STEEL CHANGES CHARACTER IN HEATING.

(1) When a piece of steel is heated in connection with a pyrometer, its temperature is seen gradually to rise until 720 degrees C. is reached, when the instrument remains stationary for a short time—showing an abnormal absorption of heat by the specimen; the pyrometer needle then resumes its journey, says *The English Mechanic*. If the piece now be allowed to cool, a point is reached at 680 degrees C. where the pyrometer again arrests, indicating an abnormal evolution of heat; this is called the recalcence, and the temperature of the steel often rises to such a degree that it can be seen to glow. (2) When carbon is added to iron, either by cementation (as in case-hardening) or by melting together in a crucible, a definite carbide of iron is formed (Fe₃C). If a piece of carbon steel be heated to 720 degrees C., the carbide which it contains dissolves in the mass, and forms a solid solution of carbide of iron in iron, accompanied by an absorption of heat. On cooling suddenly this solid solution is retained in the cold, and the steel is hard. But suppose after passing through the arrest point on heating that the steel be allowed to cool gradually, then at 680 degrees C. the carbide of iron crystallizes out with evolution of heat. Under the microscope the cold steel now is seen to consist of separate particles of carbide of iron and iron *per se*. In this condition the steel is soft. So that the degree of hardness obtained after heating to above 720 degrees C. depends upon (a) amount of carbon contained by the steel, (b) rapidity of cooling. Notwithstanding all the published nostrums, there is no virtue in the chilling liquid beyond the degree of rapidity with which it can absorb the heat from the steel. Tempering simply consists in heating hardened steel until the desired amount of carbide has fallen out of solution. The effect is similar to a mild quenching. Tempering colors are simply surface oxidation effects, used as rough temperature indicators, the colors varying with the depth of oxidation, and consequently with the amount of heat remaining in the steel. Annealing consists in heating the steel to a point below 720 degrees C. and slowly cooling, so that all the carbide may fall out of solution. The above must only be taken as a rough outline of the theory; there are often complicating factors.

EFFECT OF SIZE ON THE THERMAL EFFICIENCY*

By H. L. CALLENDAR, F. R. S.

THE thermal efficiency of an internal combustion motor, defined as the ratio of the work done to the equivalent of the heat of combustion, is limited chiefly by two sources of loss. (1) Part of the heat is necessarily lost during ignition and expansion to the cooler walls of the cylinder. (2) The heat remaining in the exhaust gases at the end of expansion is rejected unused. Losses of the first kind depend on the temperature of combustion, on the surface exposed, and other conditions, and are in part avoidable. Losses of the second kind depend chiefly on the properties of the working fluid and on the limitations of expansion, and are in a sense unavoidable. The loss of efficiency from this cause may be calculated for any given conditions in a manner which is well understood. Losses of the first kind cannot be directly calculated in any simple manner, but may be deduced by comparing the performances of actual engines with those of ideal engines in which losses of the second kind are calculated and allowed for. In discussing losses of the first kind, which form the main subject of the present paper, it is therefore necessary first to consider briefly the case of an ideal engine in which there is no loss of heat to the walls of the cylinder, but only the necessary loss due to incomplete expansion.

Air Standard Efficiency.

For an internal combustion engine in which the ratio of expansion is equal to that of compression, assuming the working fluid to possess the properties of a perfect gas of constant specific heat, and supposing that there is no loss of heat to the walls of the cylinder, the fraction of the heat of combustion rejected unused at the end of expansion is given by the ratio T''/T' of the absolute temperature T'' at the end of expansion to the maximum temperature T' . The thermal efficiency, or the fraction of the heat converted into work, is $1 - T''/T'$. If the ratio of expansion or compression is denoted by r , and the ratio of the specific heats of the gas by γ , the ratio of the temperatures T'/T'' will be $r^{\gamma-1}$, and the expression for the variation of the ideal efficiency in terms of the ratio of expansion becomes,

$$\text{Ideal efficiency} = 1 - (1/r)^{\gamma-1} \quad (1)$$

If the working fluid is a mixture of diatomic gases such as air, for which the ideal value of the ratio of specific heats is $\gamma = 1.40$, the value of the index $\gamma - 1$ is .40, and the formula becomes,

$$\text{Air-standard efficiency} = 1 - (1/r)^{.40} = E \quad (2)$$

If the working fluid is a perfect gas of constant specific heats, but with a different value of the ratio γ , the ideal efficiency will be different from that of the air-standard for the same ratio of expansion. The "Relative Efficiency," or the efficiency relative to the air-standard for the same ratio of expansion, is found by taking the ratio of the efficiency to that of the air-standard.

Relative Efficiency of Actual Engine.

The working fluid in the actual engine is not a perfect gas. It approximates to a perfect gas in that the product of its pressure and volume, pV , is nearly proportional to the absolute temperature T , but the specific heat is not constant, and is not the same before and after ignition. The ratio of the specific heats is different during compression and expansion, and there is a change of molecular volume in the process of combustion. Formula (1) for the efficiency does not therefore apply accurately. Nevertheless, it has been shown by experiment that the variation of efficiency with compression-ratio follows very closely that of the air-standard, or that the relative efficiency of a given engine is nearly independent of the compression-ratio under similar conditions of running. The actual efficiency is found to be about 60 per cent. of the air-standard for an engine of moderate size under good condi-

tions. Part of this defect of 40 per cent. is unavoidable, being due to the fact that the ratio of the specific heats of the products of combustion at working temperatures is much less than that of air; the remainder is chiefly due to loss of heat during ignition and expansion, which depends on the size of the engine and other conditions.

Properties of the Working Fluid.

In order to estimate the unavoidable loss of relative efficiency, it is necessary to consider the properties of the working fluid. The rise of temperature and pressure observed in the rapid combustion of an explosive mixture is only 50 or 60 per cent. of that calculated on the assumption that the whole heat of combustion is developed, and that the specific heats of the gases have the values observed at ordinary temperatures. The defect has been explained by supposing either (1) that the combination is not complete, and that some dissociation persists at high temperatures, or (2) that the specific heats of the products of combustion increase considerably with temperature. The two interpretations are often regarded as diametrically opposed, but it is probable that they are merely different ways of expressing the same thing. It is most likely that all change of specific heat is really due to internal work of molecular re-arrangement, which is a necessary accompaniment of dissociation; and conversely, that no dissociation can occur without an apparent change of specific heat. It is highly probable that some of the products of combustion remain dissociated, or that unstable endothermic compounds are formed in complicated mixtures at high temperatures. But the resultant effect can be consistently represented for the present purpose as an apparent change in the specific heat. Values of the apparent specific heats of various gases have been obtained by Mallard and Le Chatelier and other observers, by observing explosion-pressures in closed vessels. More recently the apparent specific heats of the actual products of combustion in the cylinder of a gas-engine under working conditions have been deduced by Dugald Clerk by a most ingenious dynamical method (Proc. R. S., Vol. 77, 1906) which gives the specific heat directly in terms of work done by the piston in compressing the gas. The conclusion from these experiments was that the apparent specific heat of the products of combustion reached a nearly constant limiting value at a temperature somewhat above 1,000° C., and that the ratio of the specific heats was nearly constant, and equal to 1.29, for the greater part of the expansion curve at ordinary working temperatures. From the values of the apparent specific heat so obtained, Clerk was able to deduce the ideal limit of efficiency of the gas-engine assuming no loss of heat to the walls of the cylinder.

It must also be remembered that, as Burstall and Hopkinson have shown, there are very large differences of temperature existing in different parts of the cylinder of a large gas-engine immediately after combustion is complete. The data for the specific heats at the higher parts of the range, approaching 1,600° C., are therefore more uncertain and difficult to obtain, and may be affected by constant errors. If the specific heat does not reach a limit, but continues to increase at higher temperatures—as other experiments appear to indicate, and the phenomena of dissociation would lead us to expect—the limiting value of the relative efficiency (assuming no heat loss to the walls) would be less than 0.80. We may conclude on this ground that at least 20 per cent. of the defect of the actual efficiency from the air-standard is to be explained by the properties of the working fluid, and is therefore unavoidable.

Variation of Efficiency with Size.

It is generally admitted that, other things being equal, a small engine is less efficient than a large one. Both the thermal and the mechanical losses are greater in proportion in the smaller engine,

*Extract from paper read before The Institute of Automobile Engineers, London.

but of the two the thermal losses are usually the most important. The most obvious method of investigating these losses in relation to size is to make a number of experiments on similar engines of different sizes under similar conditions, and to obtain an empirical formula to represent the results as a function of size.

It is a very difficult matter to obtain a series of exactly similar engines of widely different sizes, and to ensure that the trials are made under precisely similar conditions. A less direct method which should be employed in conjunction with the first, is to study the variation of the losses under widely different conditions in a single engine, so as to investigate the effect of different conditions of running, and to deduce, if possible, the laws of variation of the losses in question.

Experiments with a Small Motor.

In order to study this question from a theoretical point of view, I undertook a series of experiments about three years ago with a very small motor, 2.36 inches bore. The motor was fitted with an indicator capable of working with a high degree of accuracy up to a speed of 2,500 revolutions per minute. A number of thermocouples were inserted in the walls of the cylinder for observing the temperatures and estimating the losses in different parts of the cylinder. Fans were arranged for regulating the temperature, and electric and mechanical brakes for measuring the load. There were several advantages in employing a motor of this type. Owing to its small size, the losses to be investigated were greatly exaggerated, and were therefore rendered easier of detection and measurement. The conditions could be very easily and quickly varied through a very wide range as regards speed, load, etc. There was no water jacket to equalize artificially the temperatures of different parts of the cylinder, or to interfere with free access to anything. Many reliable experiments were available for comparison on other types of motors, but the small petrol motor afforded a comparatively new field. I can only give general results so far as they affect the point at issue.

Variation of Heat Loss with Speed and Temperature.

It is very commonly assumed in considering loss of heat from a gas to a surface that the rate of loss is proportional to the temperature-difference and to the surface exposed. This is true for static conditions and small differences of temperature, but is not even approximately correct in the problem under discussion. If it were true, the relative efficiency of an internal combustion engine would be independent of the size and the flame-temperature, and would increase indefinitely with the speed—results which are known to be incorrect. As a matter of fact, the conductivity of a gas increases very rapidly with temperature, which makes the heat-loss at high temperatures much greater than in simple proportion to the temperature-difference, and explains the loss of efficiency with increase of flame temperature. Part of the heat-loss is due to the fact that a layer of gas close to the surface cannot burn immediately. This would mean a nearly constant loss per explosion. Again, the transmission of heat from a gas to a surface is largely affected by the velocity of motion of the gas, which becomes the principal factor in determining the heat-loss in the cylinder of a gas-engine during combustion, where the motion is turbulent and the velocity high. Since the velocity of motion of the gases in a given engine, other things being equal, varies nearly as the speed in revolutions per minute, it is clear that, on this account, the heat-loss per explosion should be more nearly independent of the speed, and that there should not be any marked increase of mean pressure with increase of speed. There are doubtless many disturbing factors, too numerous to mention, which require careful consideration and adjustment, in order to arrive at the correct result. For very low speeds, the effects of leakage and static cooling tend to reduce the efficiency. For very high speeds ignition lag and gaseous inertia produce the same effect. It is essential to see that the engine gets the same quantity of the same mixture per stroke, and that the maximum pressure is developed at the same point. But if these and other

precautions are observed it will be found that the relative efficiency is nearly constant over as wide a range of speed as the design of the engine permits. In any case there will be a very flat maximum value of the efficiency at some particular speed which is not in general far removed from the normal speed of the engine.

Variation of Heat Loss with Size.

Assuming on the above grounds that the greater part of the heat-loss per explosion for a given diagram and flame-temperature is independent of the speed to a first approximation over a wide range, it should be simply proportional to the surface exposed and independent of the time of exposure. This part of loss expressed as a fraction of the heat of combustion should, therefore, vary as the ratio of surface to volume during and shortly after ignition. In other words, the loss of relative efficiency in similar engines of different size under equivalent conditions of running should vary inversely as the linear dimensions. The loss of efficiency may be taken to vary as A/D , where D is the diameter, and A an appropriate coefficient depending on the form of the surface, which remains constant so long as the form is the same. It is well known that any change in the form or extent of the surface of the combustion chamber produces a very marked effect on the efficiency.

The losses may vary from 20 to 40 per cent. They are far from negligible, and must evidently be taken into account in comparing motors of different sizes. Since the B.H.P. values are in all cases the most reliable and the most easily determined, and since the formula appears to represent them satisfactorily, we must assume that the variable part of the mechanical efficiency can be represented by the same type of formula as the variable part of the thermal losses. This effects a considerable simplification in applying the formula.

The considerations above discussed have an important bearing on the question of a rating formula. For general descriptive purposes it may be admitted that the rating formula adopted by the Royal Automobile Club, namely:

$$\text{Nominal B.H.P.} = 0.40 D^3 \text{ per cylinder, (A.C.)}$$

provides all, or nearly all, that is required. This formula is equivalent to assuming a normal piston speed of 1,000 feet per minute, and a mean effective pressure of 67.2 lbs. per square inch per explosion as corresponding to the B.H.P. There is no doubt that a series of geometrically similar motors, differing only in size, should be capable of running at the same piston-speed so far as the principal inertia stresses are concerned. But if such a formula is applied to the award of prizes in competitions, it may lead to undesirable departures from good design, since considerable advantage may be obtained by varying factors of which no account is taken in the formula. The principal factors unaccounted for in the A. C. rating are, (1) Variation of mean pressure with compression-ratio. (2) Variation of mean pressure with size. (3) Variation of piston-speed with ratio of stroke to bore. It is interesting to consider how far account may be taken of these factors, without unduly complicating the formula.

(To be concluded.)

FINISHING AUTOMOBILE CYLINDERS.

In spite of all claims of boring automobile cylinders complete at one setting on the machine, I do not believe it is good practice, says I. B. Rich, in *The American Machinist*. Whether they are to be finished by grinding or by a second passage of the boring tool, I believe the castings should be given time to relieve the initial strains as well as the changes set up by removing the inner skin of the casting. And I am naturally pleased to learn that some builders of automobiles are even going further than this. After being rough bored they are placed in an oven or furnace and held at approximately the heat at which they run when in use, for a number of hours. They are then given the finishing cut in the boring mill, and while this may be an unnecessary refinement, it certainly seems as if the cylinders should keep their shape better in actual service.

LETTERS INTERESTING AND INSTRUCTIVE

Advisability of Changing the Driving Ratio.

Editor THE AUTOMOBILE:

[770.]—I have a 1906 Maxwell speedster, 10 to 12-horsepower, with a maximum speed of 50 miles an hour. It is geared 3 1-2 to 1. If I change the gearing to 4 to 1, how much will it reduce the maximum speed? Also, how much will it reduce speed on low gear? How much increase in power would I get for low grades and muddy roads? I prefer power to speed, so would it pay to make the change? Please answer through "Letters Interesting and Instructive."
SUBSCRIBER.

Salt Lake City, Utah.

You do not state in your letter what size wheels your car is equipped with, but assuming that the latter are 30 inches in diameter, the cars speed on the direct drive would be reduced by more than 25 per cent., provided, of course, the motor speed was the same in both instances. With your present gear of 3 1-2 to 1 the motor must make 1,900 to 2,000 r. p. m. for the car to attain a speed of 50 miles an hour; figuring on the same basis, the motor speed would have to be increased to 2,600 r. p. m. or over, in order for the car to attain the 50-mile-an-hour rate with the lower gear. The reduction in speed on the low gear would naturally be proportionate to ratio the latter bears to direct drive.

Strictly speaking, there would be no increase in power, the output of the motor would remain the same regardless of the gearing, so long as it runs at its normal speed. But the capacity of the car to climb hills and negotiate bad roads would be increased in about the same proportion as the speed is increased; in other words, it would be possible to keep the motor running at about its normal speed under correspondingly more adverse road conditions. The question as to whether it will pay to make the change will depend upon the character of the country that the car is most used in. If the latter abounds in hills and bad roads, the fitting of a lower gear would be beneficial for the reasons already set forth, but if there is a great deal of running done on comparatively level roads, there would be an objectionable tendency for the motor to race. The 4 to 1 axle would give plenty of speed for all usual purposes, particularly in a hilly country.

Automobile Fire Engines and Street Cars.

Editor THE AUTOMOBILE:

[771.]—We are constantly reading, in the periodicals devoted to the automobile industry, of automobile fire engines and street cars in use in foreign cities. But we never hear anything of these modern inventions in this country. Is it really true, as I have often heard, that the United States is backward in the development and application of the automobile? If not, what is the explanation of European pre-eminence in these lines?
Ogden, Utah.

BRYAN CROSSWELL.

The United States is backward in most experimental work connected with the development of the automobile, though it is the foremost country in the world in the building and use of cars of established quality. Moreover, both the automobile fire engine and street car are in use in this country. Some of the first power-driven fire engines in the world were made in New England, as far back as in 1874 and 1875, and thus antedated practically all automobile invention in all countries. Numbers of motor-driven chemical engines are in use now in different cities of the country and are doing good service, while more are being installed all the time. The automobile street car—or, more properly, the motor omnibus—is running regularly for fares on several routes in New York City, while the so-called "sightseeing" vehicles, now a common spectacle in nearly all large cities, really amount to about the same thing and may be most fairly considered the precursors of more extensive public-service installations, which there is every indication will soon be displacing rail-carried street cars for everything but the longer hauls over hilly territory. It takes time, and the automobile is now reaching such a degree of perfection as will permit extensive commercial applications of it.

Regarding the Woodruff System of Keying.

Editor THE AUTOMOBILE:

[772.]—Under "Letters Interesting and Instructive" will you kindly inform me what is meant by the "Woodruff system of keying," and also describe the "Rites governor?"

The Woodruff system of keying, which is covered by patents, consists in the use of short keys in the shape of a section of a circle, *i. e.*, the underside of the key represents a portion of the arc of a circle, while the upper side is flat, there being a slight portion of the upper part of the key made square by carrying the sides down at right angles to the top a short distance to where they intersect the arc of the circle. The keyway is made to correspond, but instead of being cut longitudinally or parallel with the shaft, as is usually the case, it is cut transversely across the shaft, the number used depending upon the holding power required. This explains the principle in a general way, though it will be understood that more than one type of key is used, and the system as a whole is adaptable to the varying requirements of this class of work. The keyseats are made with specially formed milling cutters. If you wish to learn more regarding this matter, send your address and we will refer your inquiry to the manufacturers.

We do not know the "Rites" governor, nor have we been able to obtain any information regarding it, and will accordingly have to ask if any of our subscribers can enlighten the inquirer on this subject.

Sources of Ignition Current.

Editor THE AUTOMOBILE:

[773.]—Which is the best source of current for the ignition system of an automobile—dry batteries, storage batteries, magneto, or dynamo? What are the especial advantages and disadvantages of each of these, and why is there so much variety in the way different cars are equipped with them? I know that one automobile user will be in favor of one and another in favor of another, and, of course, the individual manufacturer or dealer will argue vigorously in favor of the system he supplies, but is it not possible to base an authoritative decision upon some set of definitely established, easily-obtainable facts? With the information I possess—and it is, I believe, equal to that possessed by the average automobile user—it is impossible to form a judgment that appeals as sound. Nevertheless, I think if you could give a little space in "Letters Interesting and Instructive" to this subject, it would be a help to a great many of your readers.

Covington, Ky.

DR. D. B. MARTIN.

The "best," in one sense, undoubtedly are the dynamo and the magneto—that is, they are the only sources of current which are absolutely self-contained, and require no renewal or recharging. They have, however, their objections, one of which is that their current output varies with the speed at which they are run, which, in turn, varies with the speed of the engine, unless complicated and often undesirable regulating drives are used. Another objection, which comes from the one just mentioned, is that the small current output at low speeds may make for a certain amount of difficulty at starting, especially with the dynamo, which is a worse offender than the magneto in this regard. This difficulty is what leads to the many systems in which the combination of a dry or a storage battery for starting and a magneto or dynamo for running is met with. Dry cells are very satisfactory and reliable, but lack long life, especially when subjected to hard usage in connection with multicylinder engines. They are, though, comparatively inexpensive and readily replaceable almost anywhere. The storage battery is reliable and is capable of delivering a large amount of current on a single charging, but it requires so long for recharging that in steady service a double equipment is practically necessary—one to charge while the other is in use. And the localities where direct current, suitable for recharging, is procurable, are considerably less numerous than they were before the present increasing vogue of alternating-cur-

rent equipments. The price factor counts for much. The low first cost of dry cells practically compels their use on low-priced cars, while the storage battery, dynamo and magneto, or some combination of these, seem to be preferred for the more pretentious conveyances.

Proper Compression Space for Two-Cycle Motor.

Editor THE AUTOMOBILE:

[774.]—I am figuring on making a four-cylinder, two-cycle, 3 1/4 by 4-inch gasoline engine, and am somewhat confused as to the proper size to make the combustion chamber. Will you kindly state through your "Letters Interesting and Instructive" column what size would be the most satisfactory?
C. U. I.
Kansas City, Mo.

The requirements of your question are rather ambiguous, as you fail to state what you wish the motor to be most satisfactory for, though from the dimensions given we presume it is intended for an automobile motor and it is further desired to obtain as much power from the completed engine as is consistent with good practice, considering its size and design. In cases where there is no clearance beyond that of the cylinder itself, the compression space may readily be determined by making it a certain proportion of the length of the stroke. As the two-cycle cylinder is perfectly straight and unencumbered by valve chambers or other disturbing factors, this method is applicable. It is customary to make the compression space equal to or less than one-third the volume displaced by the piston, so that in the case of the engine you contemplate building, taking four inches as the length of the stroke, the compression space could be made one inch or less, according to the degree of convexity of the cylinder head, as well as the counterbore, having considerable bearing on the matter. The compression to be used should be established first, as on this will depend the proper proportions of the piston pin, connecting rod and crankshaft.

What Materials Are Used in the Gearless Transmissions?

Editor THE AUTOMOBILE:

[775.]—I would like to ask a few questions concerning detailed features of the gearless transmission, a description of which recently appeared in "The Automobile." First, what metal is used in the construction of the friction plates, and, second, what are the latter faced with? An answer will greatly oblige a two-years reader of your paper.
H. V. B.

If you will again refer to the description of the features of construction of the gearless transmission which appeared in THE AUTOMOBILE, issue of May 9, page 788, you will note that this device does not embody any friction plates as such—that is, not in the sense that the term is generally understood with reference to the usual type of friction transmission employing two disks brought together at right angles. This is really a friction transmission of the planetary type employing mutually engaging internal cones and cages of rollers as the friction members, as will be seen from the illustrations of it that were reproduced.

We do not know just what particular metals are used in its construction, but presume that these differ in accordance with the service required of the different parts, the majority, however, doubtless being of a good quality of steel. Nor can we say what the friction rollers are faced with, but have no doubt your communication will fall under the eye of the designer of the transmission, and, unless the matter be a trade secret, further information will be forthcoming which will be published in a later issue.

A New Use for Chromium.

Editor THE AUTOMOBILE:

[776.]—As a repairman in an automobile shop, it struck me sometime ago that metallic chromium would be a very suitable material for the contact points of vibrators or tremblers. The extreme hardness of this metal, its infusibility, and its resistance to corrosion constitute insurance against the three chief troubles that beset the ordinary platinum points—wear, fusing, and tarnishing. I found it impossible by any method I knew to solder or braze the chromium points in place, and because of its hard and brittle nature, and almost complete lack of malleability, I had to file the points out of the solid material. What I wish to know is: Has chromium been previously used in this manner, and is

there any better way of working it than that of filing it out? Also, is there any method of soldering or brazing it? Once in place, it seems to give excellent results, though I have experienced some trouble with loosening of poorly secured points.

Waterbury, Conn.

HOMER VAN BRUNT.

The account of your experiments is very interesting, and in view of the high price of platinum, and the other well-known unsatisfactory features you mention, it may become a matter of considerable importance. There is no state of chromium, so far as we are able to ascertain, in which it is easy to work, no matter to what temperature it is subjected. We are even surprised that you were able to file it, and should think grinding necessary if the metal you have been using is pure. We also are unable to find any means of soldering it, and should be pleased to hear from any of our readers who can help out with suggestions. If your work has been anticipated, we are unable to recall it, though the writer has an impression that somewhere, a year or so ago, he read something along this line.

The Automobile Plow Again.

Editor THE AUTOMOBILE:

[777.]—Why is it that so little progress is made in the manufacture of motor plows and other motor-driven agricultural machinery, such as planters, sowers, harrows, cultivators, mowing machines, harvesters, etc.? It seems to me that there is a great field, and probably a considerable actual demand, awaiting the appearance of such machinery. No one who has ever had experience in it needs to be told how onerous most classes of farm labor are, and how much to be desired is the machine for displacing the horse, which, despite the length of his service, is in many ways inefficient and inadequate. It is my idea that something on the order of the motor forecarriage or tricar, capable of having attached to it different kinds of trawling apparatus, would be most available, since it could be then "hitched up" to whatever particular duty there might be at hand. Is such a device regarded as impractical, would it be prohibitively expensive, or what is the reason that there are no apparent signs of its coming?

Dallas, Texas.

CALVIN A. STARBUCK.

Probably a chief difficulty in the way of the particular progress you seem so earnestly to desire is the fact that the average tract of farm land is more or less hilly, and automobile vehicles of no class operate very well on hills where there are no roads. Some highly successful work has been done, nevertheless, in the direction of what you outline. For example, in England there is the Ivel agricultural motor, which plows, harrows and cultivates, and is in fairly extensive use. In this country, the International Harvester Company people, who now make a "buggy-type" automobile, are understood to have done considerable experimenting with an automobile reaping machine. This machine worked very well, but was never marketed because of a variety of reasons, chief of which were a rather high first cost and a lack of adaptability to rough ground. This was some years ago, and it is altogether probable that a marked commercial success might attend more up-to-date experiments, in which all of the recent progress of the art could be availed of. In Germany and in France, where more automobile pioneering has been done than in other countries, a good many motor vehicles are in use for agricultural purposes and are thoroughly successful. The probabilities are that the future will see much extension of their use and improvements in their qualities, while denatured alcohol very likely will be the fuel—thus giving an incidental but very positive impetus to agricultural enterprise generally. The traction engine, which has been a standard farm appliance for forty years, is a form of agricultural automobile, and in many parts of the west is used to tow gang plows, combined harvesters, and the like.

Wanted—a Forty-Passenger Electric "Rubbernecker"

Editor THE AUTOMOBILE:

[778.]—Will you kindly advise me where to buy a reliable electric 35 or 40-passenger sightseeing car for the least money?
New Orleans, La. TULANE AUTOMOBILE COMPANY, LTD.

This is something that falls outside the province of this department to answer directly, so we have accordingly communicated your inquiry for particulars to the leading makers of this type of vehicle, requesting them to send you the information.

EARLY JUNETIME HAPPENINGS OF THE CLUBS

First Rowe Trophy Contest to Be Held June 15-16.

BALTIMORE, MD., June 3.—The Automobile Club of Maryland, which, by deed of trust, becomes the custodian of the H. M. Rowe touring trophy, has accepted the conditions imposed by the donor, and will carry out the conditions of the gift, which prescribe that there shall be an annual contest of three runs annually, the first of not less than 150 miles, the second of not less than 250 miles, and the third of not less than 400 miles. The winner of the contest for each year shall be that car which has the least number of points scored against it for the three runs comprising the year's quota, but the trophy will remain in the custody of the Automobile Club of Maryland, and the name of the winner of each year's contests will be suitably engraved thereon. The contest for the Rowe trophy is open only to members of the Automobile Club of Maryland, and the first contest for the year 1907 has been set for June 15-16, to Hagerstown and return. The donor is Dr. H. M. Rowe, the club's president.

Details have been completed by the Automobile Club of Maryland for the third annual outing of orphans to be given June 12. One thousand orphans from the various institutions throughout the city will be taken in 200 cars that will be prettily decorated for the occasion. The outing will begin with a short parade through the city and Druid Hill Park, after which the party will go to Electric Park. Various amusements will be participated in by the children at the resort, after which supper will be served. In order to prevent any recklessness on the part of drivers a large detail of officers will go along on the trip.

Texans Plan a 1,000-mile Endurance Contest Across State.

FORT WORTH, TEX., June 1.—Among the features for advertising the State of Texas which the 5,000,000 Club of Texas is planning is a 1,000-mile endurance automobile contest across the State from El Paso to Texarkana, to be held next fall. The club was organized several months ago for the purpose of bringing immigration into Texas, so that the population of the State will reach the 5,000,000 mark by the time of the next government census. The club has the backing of the best business men, and is spending money in a variety of ways to accomplish its purpose, and has set aside \$5,000 for the purchase of suitable prizes for the auto contest.

The purpose of the race is to secure the advertising which it is considered will result from the fact that a 1,000-mile race can be run in one direction across a single State. The roads, where there are roads, are only fair, but most of the run will be in a country where the prairie can be used as well as any road. A meeting of the board of governors of the 5,000,000 Club will be held in Fort Worth, June 14 and 15, and it is probable that action on the race will be taken at that time. The route of the race will undoubtedly follow the Texas Pacific Railroad across the State, although there is a chance that the Southern Pacific will be followed from El Paso to Houston, and then the I. G. N. route northeast through the State be taken.

Geneva Automobile Club Holds Its Initial Run.

GENEVA, N. Y., June 3.—Thirty-one cars carrying approximately 100 passengers participated in the first run of the Geneva Automobile Club, held May 28. The trip was to Canandaigua, and was preceded by a short parade through the principal streets of the city. The trip was in the nature of an endurance run, the first prize for which was an automobile clock donated by the Geneva Automobile Company. F. C. Dilman and C. S. Burrall were tied for the prize, both of whom lacked two points of a perfect score under the rules. At Canandaigua a fish supper was indulged in and the return run was made in the evening.

Hartford A. C. Holds Its Orphan Day Run Early.

HARTFORD, CONN., June 3.—Owing to the fact that many members of the Automobile Club of Hartford depart for their summer homes prior to June 12, the date set for the national observance of Orphans' Day by the American Automobile Association, it was decided to celebrate the day on May 25. Fifty-two automobiles were tendered the committee in charge and about 200 children 95 of whom were from the Hartford Orphan Asylum, and the balance from the organized charities of the city, were given an outing. The run extended to Middletown and was in charge of President W. F. Fuller, Vice-president C. H. Gillette and Secretary Guy K. Dustin. On the return to Hartford, about 5 o'clock, lunch was served by Caterer Besse, the Pope Manufacturing Company, the Electric Vehicle Company, the Hartford Rubber Works, the Billings & Spencer Company, the Veeder Manufacturing Company, the Whitlock Coil Pipe Company, Brown, Thomson & Co., the Miner Garage Company and the Palace Automobile Station acting as hosts.

The Automobile Club of Hartford will give an outing yearly to the orphans the latter part of May each year.

Great Racing Enthusiasm at Guadalajara, Mexico.

GUADALAJARA, MEXICO, May 18.—Great enthusiasm is being manifested here over the successful two days' meet which was held May 12-13 under the auspices of the Jalisco Automobile Club, and there is promise that next year's events will rival some of the big races held in the United States. It is proposed to raise a fund of \$50,000 to improve the race course, and it is certain that there will be no lack of entries for the meeting. The Pope-Hartford people, whose car won the Jalisco cup at the recent meeting, is sure to be represented, and French, Italian, German, English, and American machines, all of which have representation in Mexico, will be entered to contest for its possession. Particular credit is due to Alfonzo Fernandez Somellera, vice-president of the Jalisco Club, who was the moving spirit in arranging the races, and is the donor of the Jalisco cup.

Harrisburg Club to Have July 4 Climb.

HARRISBURG, PA., June 3.—The Motor Club of Harrisburg is making elaborate arrangements for a hill-climbing contest which will be held on the Fourth of July. The climb will likely take place up Peter's Mountain, which is about ten miles from this city. The hill now being considered is over a mile in length and has several steep grades. Much interest is being shown in the contest and many entries are expected.

The Motor Club has set aside Saturday, June 15, for its annual Orphans' Day. On that day one hundred cars will be put at the disposal of the Exhibition and Runs Committee and the orphans of the six local charitable institutions will be taken a ride over the twenty-four miles of paved streets and out into the country over the city park system.

Detroiters Will Visit Grand Rapids Club.

DETROIT, MICH., June 3.—With winter weather still prevailing, making motoring anything but enjoyable, members of the Detroit Automobile Club are formulating plans for the summer's campaign, under the energetic direction of President Harry Skillman and his associates. The clubhouse at Pine Lake has been given a thorough renovation and was opened for the season on Sunday, May 18. The formal opening will be held some time later, and an all-day's pow-wow is being arranged, with numerous novel features in connection. Runs are also being planned to various points in the State, including a visit to the Grand Rapids Club. New members are being added rapidly.

Permanent Conditions Existing in Making Autos. Nothing illustrates the settled condition of prosperous solidity to which the American automobile industry as a whole has attained than the set plan of campaign which the established manufacturer has adopted in outlining his year's work. The haphazard conditions that characterized earlier days where both the manufacturing and the selling ends were concerned have given way entirely, and in their place have come system and method which older industries were years in establishing. With the present month both the manufacturing and selling seasons for what are rather ambiguously termed 1907 models, draws to a close, so far as the manufacturer is concerned.

All the material ordered a year or more ago has been converted into the number of automobiles which their maker then undertook preparations to turn out. All but a small proportion of the cars thus built have been delivered to the dealers and have found their way into the hands of their new owners, and within the next thirty days or less the few remaining 1907 models will have traveled the same road, so that June may be said to mark the end of the automobile year, industrially speaking. Of course, not a few makers have anticipated the end of the season by several months, and their engineering departments have been busy with the forerunners of their 1908 product long before there was the slightest cessation of activity on the current models, both departments working concurrently and at full blast. But even those whose facilities have been taxed to the utmost in getting out their product in accordance with a well-defined schedule of deliveries outlined months ahead, will devote their energies to converting the plans for 1908 models that have been in the

draughting rooms since last winter, into finished machines. For the present, there is little change to be anticipated. Models that are new in more than name are promised in several instances, and developments along competitive lines are to be expected where the low-priced car is concerned, and particularly in the runabout class, but there will be little or nothing in the way of radical changes, other than what is already a matter of more or less common knowledge. The 1908 models will be in evidence in numbers within the next sixty to ninety days, but except in the case of the initiated few it will be a difficult matter to distinguish them from their immediate predecessors.

Automobiling's Extensive List of Events Tells a Story. Thousands attended the big list of events that took place on Decoration Day, and in the daily prints of the following morning more columns were devoted to telling the holiday story of automobiling than ever before in the comparatively brief history of the motor-driven vehicle. Endurance runs, hill climbs, and track races were held in various parts of the country, and the liberal space given for the news of the competitive form of the industry's pastime feature accentuated the widespread interest of the general public. For some time to come, according to our belief, it is a good investment for makers and agents to support in reasonable degree these events which serve to attract a considerable number of people to the wonderful improvement in the automobiles of to-day as compared to the attractive though somewhat uncertain cars of a couple of years ago. The time is near at hand when it will be a difficult matter to outline contests that will extend the automobile within many degrees of its capabilities. Even now there are perplexing ties involving many cars in numerous events, indicating general excellence, but the securing of a single cup winner is scarcely possible except where speed without reference to reliability is the deciding factor, and even then it is often by margins of fractions of seconds. Instead of the endurance of the car, the battle is resolving itself into a test of the physical strength and nerve of the driver, which might bring with it the unfair blaming of a car through the weakening of its pilot and not because of any flaw in its mechanism.

The Need for Educating the Public.

We have been so busy educating the man who has saddled himself with the responsibility of an automobile, or who has exhibited any intention of transforming a handful of banknotes into a glittering machine on four wheels, that we have totally ignored the poor mortal who does not possess, and has no hope of possessing, an auto in any form or shape. As a consequence, the man who has not got an automobile, and does not want one of the "darned things," has made special laws for us with as much wisdom as might be expected from a person knowing absolutely nothing of the subject. Buttonhole any man on the street who chatters glibly of legal limits of eight and ten miles an hour and ask him to indicate what such a rate of travel means. Not one man in a hundred can indicate with any degree of accuracy the speed at which a vehicle is moving, and the percentage is smaller of those who know the relative stopping powers of automobiles, horse vehicles and trolley cars. Yet it is the ninety-nine which make the laws. Because of this vagueness the campaign of a speedometer firm in showing the public at what rates of speed we travel is to be commended. Useful work might be done by trade associations in organizing stopping competitions in some public spot between various types of mechanical and horse-drawn vehicles. The results would astound the public. We should also insist on the incorporation in school curriculums of plain teaching on how to behave in crowded thoroughfares. The need for it is self-evident to any who observe the relation of the pedestrian to drivers in our cities. Rural inhabitants need to be told how to handle horses when brought into contact with automobiles. In some parts of Europe they are so educated by the schoolmaster and by clear, concise advice issued by trade associations.

CHANGES TO BE ASKED IN MARYLAND LAW.

BALTIMORE, Md., June 3.—Members of the Automobile Club of Maryland, together with other owners and dealers in this city and State, have decided upon a number of changes in the automobile laws of Maryland which they will request the next Legislature to make. One of the most important changes desired is the raising of the speed limit from twelve to twenty miles on open roads and to have the present rate of twelve miles an hour prevail on the stretch of those roads that are frequented by vehicles of every description. The autoists will also ask the Legislature to prohibit local or municipal authorities from passing local ordinances which conflict with the State law in regard to speed except in public parks and in the regulation of parades, etc. In some of these localities ordinances have been passed which make it unlawful for any sort of vehicle to go faster than six miles an hour.

The motorists favor a change in the law as it relates to non-residents. The present law says that before coming into this State non-residents must write ahead and get a license in Maryland. In writing for a license the prospective visiting motorist must give a description of his car, send \$3—the cost of the license—and send an affidavit to the effect that he knows how to run a machine. Automobilists of this State contend that many visitors stay away from Maryland because of these strict requirements, and that the State may be passed by entirely by the Glidden tour because it has been impossible thus far to make an arrangement to exempt the tourists from taking out Maryland licenses.

Efforts will also be made to provide dealers with a distinguishing number for a license registration, duplicates of the number to be used on all cars while in their possession. Upon the sale of any such motor vehicle the purchaser is required to take out a license in his own name. Under the present law a dealer is required to take out a new license for every new car he purchases before it can be used on the roads for demonstrating.

Purchasers of new cars will also ask to have assigned to them their former registration numbers. Autoists who are pioneers in this State naturally feel proud of that distinction, and if allowed to re-register new cars under the first number taken out by them that pride would be gratified. They would expect to pay for each new registration, their only request being to be allowed to keep the old number.

EXTENDING A PREVIOUS CUSTOMS RULING.

WASHINGTON, D. C., June 3.—The Secretary of the Treasury has informed the Collector of Customs at New York that the regulations of January 31, 1905, providing for the allowance of drawback on the exportation of automobiles manufactured by the Locomobile Company of America, of Bridgeport, Conn., with the use of imported rubber tires to which valves of domestic manufacture are fitted, have been extended, so far as applicable, to cover the exportation of automobiles manufactured by the Pope Manufacturing Company, of Hartford, Conn., with the use of imported tires, in accordance with their sworn statement, dated May 3, 1907, filed with the Collector in New York.

MORE RIGID ENFORCEMENT OF JERSEY LAW.

TRENTON, N. J., June 3.—Commissioner Smith of New Jersey has sent communications to the police departments of the State and the Boards of Freeholders of the different counties urging their co-operation in the enforcement of the automobile law, which recently has suffered many violations. Mr. Smith makes it clear that it is not within the power of his department to perform police duty, and therefore that part of the work must be done by the county authorities. Motorcycles are being spoken of very highly for this work and they have so many advantages in the way of low first cost, economy of maintenance and ease of handling that their adoption is very probable.

GLOBE-GIRDLER GLIDDEN TO BE ON A.A.A. TOUR.

BOSTON, June 3.—Charles J. Glidden, donor of the touring trophy bearing his name, and famous for his many tours in all parts of the world, is very well satisfied with the route as laid out by the A. A. A. touring committee. He has made arrangements for participating in the tour, and has accepted an invitation to accompany the tourists as a guest, though he will not drive a car. Mr. Glidden is somewhat disappointed that the Massachusetts automobilists are taking so little interest in the tour, but he hopes to see entries from clubs of this State.

Tentative plans for continuing his globe-girdling tour of 50,000 miles have been made by Mr. Glidden, and he will start for Europe as soon as the A. A. A. tour is completed. He still needs about 10,000 miles to complete the distance he set out to cover several years ago, and he plans to add several thousand miles this summer in Great Britain and the Continent by making three separate tours.

One of his first notable trips was to cross the Arctic Circle in Sweden several years ago. At that time he desired to travel in Norway, but the restrictions imposed by the authorities were so arduous that he gave up the plan. It was required that he should advertise his route at least six days in advance in the newspapers in the towns along the route he intended to travel, and it was also required that he should have a man on horseback constantly in front of the machine to warn the people of the coming of the automobile. Recently, however, these and the other restrictions which made Norway a practical impossibility for touring, have been removed, and Mr. Glidden has just received a letter from the authorities stating that the restrictions are no more, and inviting him to travel in that country. He has under consideration, therefore, a trip through Norway to the most northerly point, the town of Namsos, about 62 degrees, North latitude. In Sweden he reached 66.33 degrees.

Besides the Norway tour, Mr. Glidden has under consideration a tour from the most southerly point of England, Land's End, to the most northerly point of Scotland, John O'Groats'. The third tour which he is planning is through France to Madrid in Spain, and then across to Lisbon, Portugal.

\$9,000 FOR INVENTOR OF NEW FUEL.

PARIS, May 28.—France is searching for a new automobile fuel. The carburant to replace gasoline must be cheaper than the liquid we now use, must be adaptable to present machine without any serious changes and must give good results. It was the Chambre Syndicale de l'Automobile, a purely trade organization, which took up the idea, after noting that gasoline rates have a tendency to rise and that there was even a possibility of a famine before all of us are old men. Brought before the Automobile Club of France, the national body heartily approved of the scheme and immediately added \$2,000 to the \$1,000 offered by the syndicate. Private members of the A. C. F. announced their willingness to contribute to the prize list, so that at present there are \$9,000 in cash for the person producing a fuel equal to gasoline for working purposes, but lower in cost. The Club's Technical Commission has been charged to draw up rules governing the competition and will have charge of the tests.

PRIZE WINNERS TO HAVE SHOW PRIVILEGES.

PARIS, May 28.—There will be special glory stands at the decennial Paris Salon for the victors in all the races, endurance tests and competitions organized during the year by the Automobile Club of France. Thus the machine winning the Grand Prix, the victor in the Criterium de France, and the first prize winners in the A. C. F. technical competitions may occupy a select position in the elegant Grand Palais without paying rent. Nearly one hundred entries have already been received for the show, which opens its doors on November 12, more gorgeous and more extensive than ever.

TO PROVE ABSURDITY OF SPEED LAWS.

If the speed laws of New York City were rigorously enforced the entire vehicular traffic would be brought to a standstill. To prove the absurdity of the present rule limiting the speed of automobiles in the city to ten miles an hour, the Warner Instrument Company has produced a giant speed indicator, 10 feet high, 4 feet in diameter, with figures 12 inches in height, mounted on an automobile chassis and driven from the transmission shaft. The accuracy of the instrument has been thoroughly tested, and it is further vouched for by a couple of independent indicators driven from the front wheels of the automobile. Running through the streets of the city the speed of the vehicle is visible to all, the intention of the Warner Company being to show the public the rates of speed of various types of vehicles, and to draw attention to the inconsistencies of the present restrictions. The first public display took place a few days ago in New York City, and was witnessed by a number of newspaper representatives, automobile club officials, and the motoring public generally.

THE AUTOMOBILE representative was delegated to swing round a circle on Broadway from Sixty-third street to Sixtieth street at the legal rate of ten miles an hour. The result was astounding. The machine was kept accurately and carefully at the regulation speed.

GIANT WARNER INDICATOR, THE SPEED LAW REFORMER.

as shown by the indicators, and at that rate of travel was passed by everything on the road excepting the heaviest teams. Every automobile, all the street cars, all buggies, all cabs, were violators of the law. In fact, the only law-abiding users of that particular portion of Broadway were, in addition to the auto carrying the indicator, a five-ton electric truck and two or three heavy teams. Had the police enforced in a wholesale manner the regulations they delight in applying spasmodically, 95 per cent. of the drivers of vehicles on Broadway would have been arrested. Another independent test with the gigantic autometer traveling north on Broadway from Sixty-sixth street at ten miles an hour for a distance of one mile showed that only three horse-drawn vehicles were within the regulation limits. On the other hand, the autometer was passed by three automobiles, four street cars, and three horse vehicles, all violators of the law.

Samuel M. Butler, secretary of the Automobile Club of America, made tests with the machine around the southwest corner of Central Park, Broadway to Fifty-ninth and Sixty-third streets. Owing to the congested nature of the streets, the autometer, whose duty it was to point out the offending drivers, was forced to slack up at times to less than the legal limit of ten miles an hour. However, said Mr. Butler, more than 50 per cent. of vehicles of all classes were violators of the speed laws.

In a conversation after the tests, Mr. Butler declared that the present system of regulating the speed of automobiles is not only anomalous but criminally unjust. "To prove its absurdity," said the A. C. A. secretary, motorists should insist on its strenuous application for a few days; the result would be that the whole vehicular traffic of the city would be brought to a standstill. Further, as at present constituted, the law gives a license to reckless driving,

for in certain congested quarters of the city ten miles an hour would be criminal. Legally, however, a man driving at ten miles an hour in a crowded downtown section, where such a rate of speed would obviously be highly dangerous, would be entirely within the law and could not be held responsible for any accident he might cause. Only one solution was possible, namely the abolition of the speed limit, individual responsibility and a thoroughly efficient system of identification for all drivers. The system has been tried in various parts of France with full justice to drivers and all safeguards to the public."

The Warner Instrument Company intends to send the giant speed indicator through all the principal cities of the United States and carry on an active campaign against the present arbitrary speed laws. By educating the public to a more just appreciation of speed, and as a protest against the application of a cast-iron law, it is hoped to pave the way to a more reasonable condition of affairs in the matter of auto legalities.

INFLUENCE OF THE AUTO ON MACHINE DESIGN.

Industrial commentators have been calling attention to the effect the increase in automobile manufacture has had in stimulating other industries, such as tire-making, body-building, upholstering, and so forth, but the most interesting and important phase of this subject is the great progress the automobile has caused in the strictly mechanical field, as represented by the advancement in the making of machine tools, according to James Joyce, the general manager of the American Locomotive Automobile Company, who is a sound authority. Automobile manufacturer represents a mechanical development that reaches far beyond mere design and construction, says Mr. Joyce. To quote him:

"This phase of the progress that has been made, and is now being made, is important because without this remarkable development in machine tools, which has been instigated by the demands of motor car making, the improvement of the automobile to its present standard would not have been possible. There has been a collateral progress in cars and the tools for making them.

"With the evolution of the automobile to a stage of practicability, there began a demand in the factories for varieties of machinery never thought of before, and this demand has continued. Not only have the automobile manufacturers had the best brains in their shops designing new machines for making various parts, but those regularly engaged in the business of making machine tools have been steadily at work in the same direction, so that the best mechanical genius of the period has been concentrated on invention of this sort. The consequent advance in factory machinery has had as much to do with the improvement of the automobile as anything else, especially in respect to attaining accuracy and interchangeability in the parts of cars.

"To enumerate the new tool machines that have been designed to meet the wants of automobile makers would be to give an almost complete inventory of the factory equipment. They are found in every department. The cost of creating and installing these machines has been tremendous, and to those who keep up-to-date, the expense is continuous. The builder of high grade cars cannot balk at any expense, however, for he knows that the future depends upon his product being as nearly perfect as possible.

"In some of this development America has been in advance of Europe, but it is a mistake to think that we use machinery a great deal more than the foreigners do. One of the later inventions in tool work is a machine for grinding cylinders. This is peculiarly an American development, as is another machine for grinding crankshafts, which insures greater accuracy than the lathe work formerly used. On the other hand, we have in the Berlet factory, at Providence, a gear hobbing machine, which cuts gears by a screw-like movement that is infinitesimally precise. This we imported, and there is nothing else like it in this country. We have also at Providence a remarkable milling machine for turning out camshafts, and this is of English design and build.

"The chief respect in which American machine work excels is in the extensive use of jigs and fixtures, by means of which the parts are made in exact replica and are therefore more interchangeable. It is probably true, also, that there has been more new special machinery invented in this country than in all the others put together. Furthermore, it is in the natural course of events that the country which produces the finest and greatest number of machine tool inventions should develop the skilled mechanics to handle them. It is these considerations, in fact, that led the great locomotive concern to do the machining on Berlet cars in their own factory here, while sending to France for the superior materials produced there."

ANOTHER SIX FROM THE OLD BAY STATE

A SILENT six-cylinder 60-horsepower automobile is the unique model produced by the Stilson Motor Car Company, 92 Renne avenue, Pittsfield, Mass. The motive power of the machine is an engine with separately cast vertical water-cooled cylinders, 4 11-16 inches bore and 5 1-2 inches stroke, with interchangeable mushroom type valves on opposite sides. Despite the multiplicity of its cylinders, the engine is particularly compact

THE 60-HORSEPOWER STILSON SIX-CYLINDER LOOKS LIKE A STURDY NEW ENGLANDER.

and the arrangement of piping is such as to give complete accessibility to every working part. The cylinders are mounted on an aluminum crankcase attached to a steel sub-frame, and all gears are completely inclosed and run in oil. Double ignition is provided by a high-tension magneto and by storage battery, spark plugs being in the cylinder heads. The water-cooling system comprises a centrifugal gear-driven pump and a special type cellular radiator of large dimensions and special design. An important matter in six-cylinder engines is the arrangement of the intake piping; this has been carefully worked out on the Stilson, and, as will be seen from the illustration of the intake side of engine, the piping is calculated to give a uniform supply of gas to all cylinders. The carbureter is of the float-feed type and is entirely automatic. Lubrication is provided for by a patent oiling system, the mechanical oiler being gear-driven.

Standard lines are followed in the matter of transmission and drive. The clutch is of the cone type with special leather face. sliding gear transmission is of selective type, giving four speeds forward and reverse, with direct drive on the high. Final drive is by bevel gears to floating rear axle, with clutch-driven hub. Ball bearings are used throughout in the transmission.

Steering is irreversible, positively adjustable to wear, with fixed wheel. Spark and throttle levers, placed on top of steering wheel, have stationary segment retaining its position independent of position of the wheel.

The framework of the Stilson "six" is of pressed steel cold rolled, with a sub-frame to carry entire power plant, and a metal dustpan completely protecting all mechanical parts. Extra heavy semi-elliptic springs are employed in front and the rear has the same type of suspension, the springs being extra long. Front axle is of I-beam section, nickel steel, with reversed Elliot type steering knuckles and oil-tempered ball bearings. Both braking

systems are on rear wheels, the foot brake operating externally and the emergency brake being of internal expansion type on rear wheel drums, bronze against steel. Thirty-four-inch wheels are carried made of grade A second growth hickory. Wheelbase is 120 inches and tread 56 inches. Any make of American tires may be had with the machine, the dimensions being 34 by 4 inches front and 34 by 4 1-2 inches rear. At the rear of the frame is a 23-gallon gasoline tank, supplying fuel under pressure to the carbureter; a pressure gauge is provided on the dash.

In keeping with the high grade of the mechanical make-up of the automobile is a roomy, comfortable, and well-finished touring body, with easy side entrances. Although a top is not provided on the standard model, the body has received the necessary strengthening irons to allow of its receiving this protection against bad weather. Standard colors are dark red, with light red running gear, trimmed with black. Other color

combinations are obtainable when ordered. The curved dash is of cast aluminum of a patented design, there are running foot-boards and metal mud guards. In the generous equipment are comprised two large acetylene headlights with B. & L. mirrors, generator, two square oil side lamps with red and green stripes on top of glass, rear oil lamp, an autochime operated by foot lever, clock, pump, jack, and full kit of tools and a foot rest. As a powerful family touring car the Stilson "six" has a handsome, comfortable appearance. Fully equipped, the weight of the machine is 2,750 pounds.

RIGHT-HAND SIDE MOTOR SHOWING DESIGN OF INTAKE.

MODEL D ALBANY RUNABOUT WITH FALLING TOP EQUIPMENT.

A BUGGY RUNABOUT FROM INDIANA.

There are four models of the Albany runabout, constructed by the Albany Auto Company, Albany, Ind., designated respectively Models C, B, D, and E. Model C chassis, which is shown below, is the one likely to prove of most interest to the general public and which best serves as a representative of the group.

Complete accessibility is obtained by placing the two-cylinder air-cooled vertical engine under a bonnet forward. Of 4-inches bore by 4-inches stroke, it develops 10-12 horsepower, and has mechanical exhaust and automatic intake valves in the head. Ignition is by jump spark, dry batteries being used. The carbureter is of the automatic float feed type.

Transmission is by metal friction disk with fiber-shod friction wheel pushed into contact with foot pedal transmitting power to countershaft, final drive being by double side chains to sprockets on rear road wheels. All speeds are obtainable from two to twenty miles an hour by operation of the hand lever, reverse and emergency brake being obtained by the same lever. On the countershaft an 8-tooth sprocket is used, 36-tooth sprockets being used on the road wheels. Steering is by inclined column operating worm and segment, with connecting bar behind the front axle. Efficient suspension is provided by four full elliptic springs reinforced by a half-elliptic spring under engine. Angle steel, 2 inch by 1-4 inch, is employed for the frame, engine and gear being mounted direct. Wheelbase is 70 inches, tread 50 inches, and weight 800 pounds. Solid cushion tires, 1 1-4-inch, are employed on 30-inch wood wheels, strongly bolted and running on double roller bearings. Both front and rear axles are tubular

DOUBLE CYLINDER CHASSIS OF THE ALBANY RUNABOUT.

and undivided, giving a road clearance of full fourteen inches. The body is of poplar, with either oak or hickory framework. The seat is upholstered, with spring cushion and back and a commodious space is left in the rear for carrying packages. Color scheme is black body, machinery aluminum and running gear red or Brewster green. Metal mud guards are provided, and the buggy is completely equipped with lamps, tools, etc., and a folding hood.

DETAILS OF THE NEW STEARNS SIX-CYLINDER.

Among the first of the makers to outline their policy for 1908 where the six-cylinder motor is concerned are the builders of the Stearns, who have had a runabout of this type in hand for some time past, and now that it has more than exceeded expectations in its try-out, the details of the new car are made public, but in the same announcement take pains to make clear their position on this much-mooted point. Actually they do not favor the six-cylinder construction, as the multiplication of the cylinders above four is superfluous, while the gain achieved does not compensate for the greater weight and complication necessarily involved. In short, they are quite content to pin their faith during the coming year on the four-cylinder motor, as they have in the past, but, not to be sidetracked where the increasing demand for a six-cylinder high-powered runabout is concerned, they have decided to enter

THE NEW STEARNS "SIX" LOOKS GOOD.

the ranks in order to meet the wants of those of their customers who are bent on having a six-cylinder car.

The new runabout is nominally rated at 45 horsepower, but it is in reality of twice the power, as the new motor has tested up to 90 and 100 horsepower on the brake. The reason will readily be apparent when it is said that the new motor is in practically every respect but a duplication of the standard Stearns motor on a 50 per cent. larger scale. In other words, two additional cylinders of the same size have been added and the features that have hitherto distinguished the Stearns motor have been retained as formerly. The four-cylinder motor is rated at 30-60 horsepower, according to which carbureter of the double system is employed, and consists of four cylinders with a bore and stroke of 5 3-8 by 5 1-2 inches. As the result of considerable study of the problem, the makers have succeeded, with the aid of an additional ball bearing, in mounting a crankshaft capable of delivering 100 horsepower, with possibly a trifle less load per bearing than is the case on the present four-cylinder mounting. A carbureter of the regular multiple jet type, together with a unique design of inlet manifolds, supplies the mixture. The double ignition system, employing a Bosch high-tension magneto on one side and a complete accumulator and coil on the other, is also a feature. Power is transmitted through an expanding band clutch and four speed gear-set of the selective type to the double side-chain drive.

MICHIGAN COMPANY TO BUILD STEAM TRUCKS.

Under the title of the Michigan Steam Motor Company, a firm has been incorporated under the laws of the State of Michigan with a capital of \$250,000, to build three and five-ton trucks, using a steam power plant of special design on which the company controls the patent rights. The officers are: J. F. MacPherson, president; R. Jossman, secretary, and R. T. Armstrong, treasurer, and the office and factory, consisting of a four-story brick building with a floor space of 26,000 square feet and independent power plant, are located at Pontiac, Mich.

The distinguishing feature of the vehicles to be built by this concern, the first of which are expected to be ready in July next, is the use of a 50-horsepower eight-cylinder compound steam motor of the Belknap type, although a number of patents are held on the generator and other essentials of the power plant to be used. The engine itself is very simple in construction, the cylinders being placed according to the twin tandem arrangement, each unit consisting of two cylinders cast integrally and each pair of units being staggered at an angle of 90 degrees on the crankcase, all the valve mechanism being placed between the cylinders, thus making the motor very compact as well as very accessible. The generators are tested to 1,000 pounds by hydraulic pressure, but have been run in tests at 350 pounds, which pressure will doubtless be adhered to. An automatically controlled fuel supply maintains the pressure at any point desired, extinguishing the fire when it rises too high and relighting it when it falls.

MORE TRADE CHANGES AT THE HUB.

BOSTON, June 3.—A notable change in local trade circles during the past week has been the purchase of the business of the F. T. Kimball Company, of the Motor Mart, agents for the Corbin, by the Corbin Motor Vehicle Corporation, which will continue the agency as the Corbin Car Company of Boston, the new concern having been incorporated under Massachusetts laws with B. B. Bassette president, E. H. Brandt vice-president, E. T. Kimball treasurer, and B. Frank Blaney secretary. The new concern will handle the New England business, and Mr. Blaney has just started on a trip with a car through the territory. He is accompanied by H. E. Wilson, formerly of the Rambler branch, who has just joined the Corbin forces.

V. A. Charles, who has been a salesman at the Thomas B. Jeffery & Co. New England branch, in this city, for several years, has been appointed manager to succeed C. E. Gilmore who recently resigned to become traveling representative of the Knox company, of Springfield. Mr. Charles is well acquainted with the New England trade and with the Rambler product, and is well equipped to look out for Rambler interests.

BIG ADDITION TO THE MORA PLANT.

NEWARK, N. Y., June 3.—Six acres of ground are being broken for an addition to the plant of the Mora Motor Car Company. The new building, situated alongside the Northern Central Railroad tracks, will be of two-story modern mill construction, 400 feet long, and, in addition to the plant now occupied, will enable the Mora Company to treble its force before fall.

The Racytype Mora Roadster is speedier than first anticipated. Several satisfied owners claim sixty miles per hour is an easy accomplishment.

LOGAN COMPANY INCREASES CAPITALIZATION.

CHILlicothe, O., June 3.—The Logan Construction Company, manufacturers of Logan motor cars, has found it necessary to increase its capital stock to \$250,000. The Logan company began business some seven years ago with an output of six cars, and to-day it is producing thirty cars a month, and is behind with its orders. While its trucks and light delivery wagons have met with gratifying success, its 20-24-horsepower runabout, which did excellently in the recent Harrisburg endurance run, is finding a ready sale.

THE RAMBLER THAT WAS CONVERTED INTO A "CHEMICAL."

REMODELING A RAMBLER INTO A FIRE ENGINE.

LONG BEACH, CAL., May 30.—With a desire of being strictly up-to-date, and having nothing readily available to meet their requirements, the fire department of this place hit upon the expedient of attaching a chemical apparatus to the rear deck of a Model 21 Rambler. This car, being regularly fitted with a detachable tonneau, it was only necessary to remove the tonneau, and set the apparatus into place, as shown in the photograph. The outfit, when completed, was put to very rigid tests to compare it with the horse-drawn type. On one occasion it reached a fire, in two minutes from tap of gong, three-quarters of a mile away, over rough streets and railroad crossings.

So successful has this outfit (which weighs 1,000 pounds and carries two men) proven, that the department here is designing several others of a more elaborate form, providing for full complement of firemen, and in some cases more elaborate apparatus. An interesting feature is that the machine was not prepared by the manufacturers of the Rambler, but was designed and adapted to a stock Model 21 chassis by the Long Beach fire department.

"BUFFALO BILL" TRIES AN AUTOMOBILE.

Should Col. W. F. Cody (Buffalo Bill) prove as efficient an auto driver as he is a horseman, automobilists will sit up and take notice when his car goes by. P. A. Williams, Jr., sales manager of the Atlas Motor Car Company, Springfield, Mass., which factory Col. Cody visited while in that city, states that his uncle, George H. A. Williams, of the Abbott-Downing Company, Concord, N. H., built the old stage coach forty years ago that is now used daily in the Wild West show.

COL. WILLIAM F. CODY IN THE 1908 ATLAS RUNABOUT.

F. S. DIMMICK IN HIS WALTHAM-ORIENT AT BRIDGETOWN.

A BIT OF AUTOMOBILING IN BARBADOES.

From the Barbadoes *Advocate*: "On Sunday last Mr. and Mrs. F. S. Dimmick motored out to Beachmont Hotel, Bathsheba, going down by way of Newcastle Hill. In speaking of the work of his car, Mr. Dimmick says that there are some very severe gradients with not the best of surface between New Castle estates and the hotel, but the car took them all cheerfully, even stopping in the middle of one of the steepest to permit a restive horse to be led by, and picking up and continuing without any trouble. The return was by way of Horse Hill, and we believe that this is the first time that an automobile has made the ascent without assistance, to say nothing of carrying its full load all the way, as did Mr. Dimmick's Waltham-Orient. An enthusiastic crowd witnessed the climb, and Mr. Dimmick was informed that all other cars attempting the hill had been either pushed or towed up. The successful accomplishment of such a feat not only demonstrates the great hill-climbing powers of the little car, but shows that its air-cooled motor is up to the hardest kind of work in this tropical climate."

SEATTLE TRIES KNOX AUTO PATROL.

SEATTLE, WASH., June 1.—Seattle's automobile patrol is in action. The car has already made its first run, going into commission last Saturday night, when it did a good day's work, and did all that could be expected of it. The car is a 20-horsepower double-cylinder Knox, and will hold twelve prisoners. The front and sides are screened with heavy netting. If the patrol proves a success a second will be purchased and placed in service as soon as the manufacturers can supply it.

KNOX AUTO POLICE PATROL IN SERVICE AT SEATTLE.

TRAVELING AUTOMOBILE NEWSPAPER PLANT.

WAUKEGAN, ILL., June 1.—Frank H. Just, a newspaper publisher, has converted a runabout Rambler into a portable newspaper office. He publishes a daily paper in Waukegan and a weekly in Libertyville ten miles distant. Editor Just built a sort of torpedo deck on his machine and inside he carries a number of type galleys. Matter that he uses in his daily is carried over to Libertyville, the galleys fitting in the deck one above another so that they do not disturb one another. Formerly the editor carried the galleys with him on a trolley line, but he finds the auto arrangement a great improvement over the interurban.

Owners of valuable horse-flesh in Lake county have come forth with a queer proposition intended to lessen the danger of horses scaring at automobiles. They claim that the animals take fright at the brilliantly painted cars only. They suggest that cars be painted a uniform color, some subdued hue, brown black or blue. The men who advance this argument say that there are more runaways from red and white painted cars than from any others.

A VETERAN FRANKLIN AND ITS OWNER.

A. B. Case, of Springfield, Mass., owns Franklin automobile 592. Recently he wrote to the maker: "My Franklin 592 has entered upon its fourth year of service. I have had the body

"BENJAMIN FRANKLIN" IN HIS FOUR-YEAR-OLD FRANKLIN.

cleaned and varnished and running gear painted and the machine looks like new." Mr. Case in a recent carnival dressed to represent Benjamin Franklin to quite good effect and with his car made a hit in the procession.

SOME "DON'TS" WORTH REMEMBERING.

From the instruction book of the Peerless Motor Car Company, Cleveland, O., the following excerpt of valuable hints to drivers of cars is taken for the benefit of our readers:

Don't try to start without the switch turned on.

Don't try to start without seeing that the spark lever is retarded.

Don't start motor without first making sure that the speed lever is in neutral position.

Don't try to run without oil, water and gasoline.

Don't crank a motor, that is, don't turn it over the compression, more than three or four times after priming. If it does not start at once there is something wrong.

Don't drive fast around corners; it is dangerous and destructive, especially to tires.

Don't allow an automobile to stand in cold weather with pure water in the circulating system. It will freeze and burst something. In cold weather use some good anti-freezing solution.

Don't run a motor fast when the automobile is standing still; there is no worse abuse.

Don't advance spark lever too fast or too far (crankshafts can be broken by injudicious use of spark advance).

BRITAIN'S CLUB SOLVING THE DUST PROBLEM

By JOSEPH F. MACKLE.

LONDON, May 23.—To-day have commenced some interesting tests organized by the Roads Improvement Association, in conjunction with the Motor Union and the R. A. C. Tar coating of roads has long been known as a satisfactory dust preventative, but the usual method of applying the tar by hand has rendered the work too costly for general adoption. The present trial has for its object the discovery of an efficient machine which will spray the tar into the top crust of the road and bind the surface material together. No less than eight machines have been entered, and preliminary trials have indicated that the work can be done much quicker and at less cost than by former methods, and in consequence a big spread of dust-laying efforts may be looked for. Having found a suitable machine, the right material must be provided and accordingly a second trial is being run to test the respective merits of seven tar preparations which have been brought forward. The present experiments have attracted much attention from road surveyors and similar officials and representatives of these, together with two well-known municipal engineers who have joined the committee, are devoting their efforts to the satisfactory solution of the dust problem—the factor militating most strongly against automobilism at the present time.

But while much can be done in the way of improvement of the highways—which are naturally not in perfect condition after sixty years of comparative disuse—car design is a matter which is much to blame for the present evil. Pressure fuel tanks at the rear have got to go, and in like manner sweeping mudguards must be abolished. Exhaust silencers blowing on the road are also great offenders and a surprisingly large number of cars transgress in this way. Much can be done with a smooth underscreen extending to the rear axle.

To give some definite idea of what is being done in this direction and also, let it be hoped, to point out the glaring offenders, the R. A. C. proposes an interesting trial on the now almost completed three-mile track at Brooklands—the world's first automobile speedway. An even coating of limestone dust will be laid down and the competing cars will be run over this at fixed speeds. Photographic evidence will be taken for the purposes of comparison, which method has been found by previous experience to give entire satisfaction.

Endurance and Reliability Runs.

While there were comparatively few entries for the tourist trophy races, the same lack of interest on the part of the trade is not manifested towards reliability contests. The Irish Automobile Club's event is in progress for the last four days of this week, seventy-five cars running in the various sections over the 600-mile course. For the Scottish Trial at the end of June a still better muster has been obtained and even the total of 105 would have been further increased had not the closing date of entry been strictly observed. Seven cars will uphold America's reputation in this event—two White steamers, two Fords, a Buick, Maxwell, and Cadillac.

The private reliability trial is becoming no less popular than these free-to-all contests, and certainly the publicity gained by a successful run well repays the expense and trouble involved. The victorious Siddeley ran through its allotted 10,000 miles with but one stop, this being an extraordinary mishap in the shape of a broken change-speed lever. The six-cylinder Hotchkiss, fresh from its long French tour, set off immediately to break this record and after reaching its 12,000th mile on English roads has now started to explore Ireland, incidentally going through the Irish Club's Trial. Later on the Scottish Trial will be essayed and thereafter the car will go on running till something happens.

The White steamer and the six-cylinder Rolls-Royce also have just concluded an 1,800 miles observed run without trouble, the

route taking these rivals to the heart of Scotland and back. Contrary to expectation, it turns out that this is not the widely announced contest which (it is said) is going to finally settle the vexed steam vs. gasoline engine question, but is merely a friendly encounter preparatory to the trial proper, which will come off in early autumn.

Show Exhibitors Object to Uniform Decorations.

At the present season of road contests it is a far cry to the shows, but it may be of interest to note that the proposed scheme of uniform stand decoration at the next Olympia exhibition has been dropped. The storm of discussion aroused by the idea foreboded its eventual abandonment, for while those firms which formerly spent large sums on striking decoration objected to their loss of distinction, the other parties who cared not for such glitter loudly cried out against the big expense of the proposed scheme. Hence this year's show, which is dated for November 11-23, will be as variegated as ever. A timely denunciation of the auto-cad who amuses himself with sirens and exhaust cut-outs has been issued by the R. A. C. committee.

ENGLAND RETAINS THE TOURIST TROPHY.

DOUGLAS, ISLE OF MAN, May 30.—Britain's most important automobile contest, the race for the Tourist Trophy, has resulted in a victory for the Rover machine, driven by E. Curtis. The heavy touring car race, run on the same course and at the same time, was won by another English machine, a 30-horsepower Beeston-Humber, driven by G. P. Mills.

Owing to a drenching rain the roads were exceedingly slippery and mishaps to valuable cars were as a consequence somewhat numerous. The authorities were so impressed with the bad nature of the road that the heavy cars were allowed an extra gallon of gasoline. The course was from Quarter Bridge, Douglas, to Peel, via Union Mills, Crosby and Ballacraigne; from Peel, via Coat road through St. Germain's to Ramsey and then back to Douglas over a mountain road to Snaefell. Six rounds of the course had to be made by the light cars, giving a distance of 241.5 miles; the heavy cars had to go round five times.

There were twenty-three machines in the Tourist Trophy class, thirteen of them being British, and nine in the heavy touring car race, six being English and three French. At the commencement of the last round six cars had a winning chance. Three miles from home A. Lee Guinness, driving an 18-horsepower Darracq, appeared a likely winner, but victory was robbed from him by his gasoline supply running out. Only four cars finished on their gasoline allowance, two in each class. They were in the light class a 20-horsepower Rover (E. Curtis), 8:23:27; 16-20-horsepower Beeston-Humber (James Reid), 8:35:17-1. In the heavy class the two finishers were a 30-horsepower Beeston-Humber (G. P. Mills), 7:11:1, and a 25-horsepower Gladiator (G. Fenton), 7:31:35:1. The average speed of the winner is about 28.2 miles an hour, compared with nearly forty miles an

FRENCH VICTORIOUS IN ISLE OF MAN HILL CLIMB

In the hill climbing competition for the *Graphic* trophy, J. E. Hutton's 60-horsepower Berliet was first in 3:40-2, J. Watson's Berliet being second in 3:45-3. Third position was taken by the English Daimler, owned by T. Henshaw, its time being 3:50-4. The contest was held on Slein Lewaigne Hill, near Ramsey, where the course has a gradient of 141 yards in 2,500 yards. The total length of the course was two miles three furlongs, and the steepest part a rise of one in twelve a mile before the finishing point. Vehicles had to be of touring type and carry four passengers. There were fourteen entries.

HOW ALBERT CLEMENT MET HIS DEATH.

PARIS, May 24.—From an examination of the spot on which Albert Clément met his death while training on the Dieppe circuit for the Grand Prix, with a Bayard-Clément machine, it appears that he took an easy turn at too wide an angle. At sixty miles an hour his car ran off the road onto the wide, grassy border. After running over this for nearly fifty yards, it was just about to straighten out to regain the middle of the road when the front wheels struck a bank of earth. Gauderman was thrown out, but Clément was carried along a prisoner in the car, which jumped twenty-five meters, fell across the road and rolled over twice. Clément suffered a fracture of the skull and of the vertebral column and expired a few minutes after.

Gauderman, who was riding with Clément at the time, and who had a miraculous escape, gives the following account of the disaster:

"We left Londinieres at seven o'clock in the morning, Albert Clément driving the machine with which he was third last year in the Grand Prix, and which I was to drive in the coming event. He was thus perfectly familiar with the car. The morning was exceptionally cold, and when we stopped at Eu to take a bowl of hot coffee, Clément bought a pair of heavy gloves and slipped a newspaper under his jersey to protect his chest. While we were here Gabriel and Rougier, who had left Londinieres behind us, passed on a touring car. On starting out again Albert said 'We will catch up Gabriel.' I am certain that Albert Clément was preoccupied or distracted immediately before the accident. Thus, although it was the machine he had driven last year, I noticed that he persisted in remaining in third speed. After Triel, on a straight stretch of road, he said:

"The machine is not pulling this morning."

"Well, you are running on third."

"So I am," he replied.

"Albert then put in his fourth, and it was on this gear that we entered the fatal turn at Saint-Martin-en-Campagne. Albert missed his turn. This is the only cause of the accident. He took the turn too wide, and in an instant was on the grassy border. We did not skid, nor did the car drift. At this moment there was no sense of danger; we did not even feel any shock from the two ditches we passed over, and of which so much has been spoken. We did not even notice the large blocks of wood which we grazed in our passage. Suddenly there was a violent shock. We had struck a bank of sand, which, being covered with grass, was not visible at any distance. I was thrown out, but I distinctly saw the car pass under me, Albert carried along with it. When I recovered consciousness Albert was dead, crushed under the car, which had turned over twenty-five meters away and was a complete wreck."

Albert Clément's funeral service was held at Saint-Pierre-de-Neuilly, the church in which his sister was married to Ferdinand Charron but three weeks ago. A subscription list has been opened for the erection of a monument to his memory.

ANOTHER GRAND PRIX CANDIDATE KILLED.

PARIS, May 30.—While driving the 120-horsepower Darracq racer originally intended for Wagner in the Grand Prix, Marius Pin entered into collision with a horse vehicle between Epernon and Rambouillet, and was killed almost instantly. The accident was caused by the horse taking fright and obstructing the road. M. Hériot, proprietor of the Louvre department store in the Rue de Rivoli, Paris, bought the machine from the Darracq Company only a few days ago, with the intention of running it in the Grand Prix with his chauffeur Pin as driver. The front part of the machine was smashed, but the engine and transmission escaped injury.

Although M. Pin had never driven in auto races, he has always been connected with powerful cars. In 1903 he was Janatzy's mechanic in the Paris-Madrid race. Last year he gained a little notoriety as the hero of an event in which an American family figured. Having missed the special boat train from Paris

to Cherbourg, two American ladies, who had booked their passage on a transatlantic steamship, endeavored to charter an automobile to carry them to the seaport. Several of the firms to whom they made their pressing demand refused the journey. Finally, C. M. Charley, of Mercedes interests, offered his private 90-horsepower Mercedes, with Pin as driver. Although the express train had got an advance of more than an hour, Pin raced out with the automobile, and reached Cherbourg a few minutes ahead of the train, thus securing for the ladies a journey across the Atlantic as originally intended.

A.L.A.M. MAKES SHOW PLANS AND TALKS ROADS.

Tuesday was managers' day at the Association of Licensed Automobile Manufacturers headquarters, for there was an all-day session of the Board of Managers, which held its semi-annual meeting in New York. As the chief results of its work, the demonstrating car will no longer be a feature of the Garden show, and motorcycles will be admitted to take their place with the cars, being placed in the commercial vehicle section. Demonstrations are not to be eliminated altogether, but they will be taken care of henceforth by local agencies from their own establishments. Owing to the resignation of Carlton R. Malbey from the show committee, Marcus I. Brock was reappointed a member of it, having retired but a few months ago.

Next to show matters, good roads came in for considerable attention, and the board appropriated \$5,000 to be used in furthering the cause, at the discretion of a good roads committee to be appointed later. E. R. Thomas, S. T. Davis, Jr., Albert L. Pope, Thomas Henderson, H. A. Gillis, and R. D. Chapin expressed their views on the question at length, Mr. Thomas being particularly enthusiastic. The committee will work in conjunction with that of the American Motor Car Manufacturers' Association and other organizations throughout the country. The handbook committee—W. E. Metzger, L. H. Kittredge and Thomas Henderson, announced that the 1908 handbook would be ready for distribution at the show. Those present at the meeting were:

Elmer Apperson, Apperson Bros. Automobile Company; H. A. Gillis and H. M. Coale, Autocar Company; W. C. Durant, Buick Motor Company; William E. Metzger, Cadillac Motor Car Company; E. H. Brandt, Corbin Motor Vehicle Corporation; M. J. Budlong, Electric Vehicle Company; J. H. Becker, Elmore Manufacturing Company; H. H. Franklin and G. H. Stilwell, H. H. Franklin Manufacturing Company; C. H. Haynes, W. M. Gunderson and C. C. Cartwright, Haynes Automobile Company; E. R. Hewitt, Hewitt Motor Company; E. H. Cutler, Knox Automobile Company; S. T. Davis, Jr., and A. W. Robinson, Locomobile Company of America; H. A. Lozier and Edward Lozier, Lozier Motor Company; C. W. Matheson, Matheson Motor Car Company; V. M. Gunderson, Northern Motor Car Company; Angus Smith, Olds Motor Works; H. B. Joy and S. D. Waldon, Packard Motor Car Company; E. H. Parkhurst, Peerless Motor Car Company; Charles Clifton, George N. Pierce Company; George Pope and C. E. Walker, Pope Manufacturing Company; Albert L. Pope, W. C. Walker and A. E. Schaaf, Pope Motor Car Company; E. D. Shurmer, Royal Motor Car Company; Aiden Sampson, 2d, Edwin McEwen, F. B. Stearns Company; C. C. Hildebrand, Stevens Arms & Tool Company; W. R. Innis and T. W. Goodridge, Studebaker Automobile Company; E. R. Thomas and R. D. Chapin, E. R. Thomas Motor Company; Fred Kuser, Walter Automobile Company; E. B. Chaifant and E. S. Church, Waltham Manufacturing Company; Thomas Henderson, Winton Motor Carriage Company.

DARRACQ MACHINES WILL ALL RACE.

PARIS, May 27.—All is now settled regarding the Darracq racers built for this season's international contests. The Darracq Company maintains its decision not to race officially as a protest against Wagner passing over to Fiat. M. Raoul d'Arnaud has bought the machine which should have been in Wagner's hands and has selected Caillois to drive it in the Grand Prix. M. Hériot, son of Commandant Hériot of the French army, has bought another and will place his own mechanic, Marius Pin, in charge of it for the race on the Dieppe Circuit. The third one has been bought by a private individual who will engage Demogot as driver, or Théry if possible.

For the German Emperor's race the three machines have been bought by Vincenzo Florio, M. Brenda, a French sportsman living in Germany, and an Italian sportsman who hides his identity under the name of d'Ollorip. These three machines will also compete in the Brescia Circuit in northern Italy.

OUR STRENUOUS CHIEF EXECUTIVE RIDES IN A REO.

For probably the third or fourth time in his life, President Roosevelt utilized the automobile as a means of conveyance, being driven out to the State Agricultural College at Lansing in a Reo with Secretary Loeb and R. E. Olds.

NEW YORK STATE "BLUE BOOK" READY.

Another of the three volumes of "The Automobile Official A. A. A. Blue Book" for 1907 has made its appearance. The second to be issued, it bears the title Volume I. and deals with New York State and Canada, with extension routes to and from the Middle West. No time or expense has been spared to supply reliable information on the districts dealt with and the constant changes in highway improvement, making the inferior road of to-day the best to-morrow, have received close attention.

As a convenience to users, a number of New Jersey routes have been included, giving the principal connections from New York to the mainland and shore lines of that State. A convenient arrangement is a preface map showing the entire country dealt with in Volume I, with figures in circles referring to the title pages of sections in the book. Much new work has been done in indicating automobile routes in the Middle West, twenty-four of the most important being outlined in clearer and better form than ever before. Special pains, too, have been taken with city maps in the West; even when it was not always possible to obtain a complete and accurate description of the highways, the routes into and through Western towns have always been prepared with perfect accuracy.

The tabular pages on automobile laws and regulations have been revised and made correct up to the time of sending the volume to press. Steamship connections to New England, Atlantic ports and the West Indies are also presented in convenient tabular form, and information on European regulations is given in the same manner. Hudson river boat lines and ferries are dealt with both tabularly and by diagram maps. The Blue Book is published by the Class Journal Company, publishers of THE AUTOMOBILE, Flatiron Building, New York City.

NATURAL RUBBER HAS A NEW RIVAL.

Harry B. Cox, a Hartford, Conn., chemist, claims to have discovered, after long laboratory researches, a substitute for natural rubber. The new substance, to which the name Halcox has been given, has a close similarity with natural rubber, can be compounded as readily as the natural gum, and can be vulcanized or cured with even greater facility. Its most important advantage is that it can be produced in any required consistency—liquid, semi-liquid, plastic, or stiffer if required. With Halcox it is claimed that there is no variation in product, each lot being identical in make-up and consistency. Cost of manufacture will allow Halcox to be produced at a lower figure than crude rubber can be worked up into a saleable form, and it is said to be capable of quick production in large quantities.

ILLINOIS NOW HAS NEW AUTO LAW.

SPRINGFIELD, ILL., June 3.—Illinois at last has a State automobile law, which places the regulation of this form of transportation entirely in the hands of the State authorities. The bill providing for the regulation of automobiling by the State became a law at midnight last Friday, without the Governor's signature, the necessary ten days having elapsed since it was placed in the hands of the Executive after having passed both branches of the Legislature. The new law will be placed upon the statute books and become effective July 1 next.

In brief, the law requires that all owners of motor vehicles must secure a license from the Secretary of State; provides for State registration and numbering of machines; defines and fixes speed limits; fixes rules of the road; provides for the registration of chauffeurs; registration of manufacturers and dealers; excepts non-residents from registration under certain conditions; in addition to numerous other minor regulations, fixes the fines which are to be collected for violations of the act.

The law is highly acceptable for the most part to automobile owners throughout the State, and was championed vigorously by the Illinois State Automobile Association. At many times it appeared as though it would fail of passage through the opposition of country members who were hostile to the section taking away the power of regulating automobiles from municipalities.

Two years ago a similar measure was vetoed by Governor Deneen, but the present bill was so drawn as to obviate all objections contained in the Governor's veto message on the subject. As the present measure was finally passed by practically a two-thirds vote of the Forty-fifth General Assembly, and as the only objection was the section taking away the power of municipalities to regulate, meeting all other objections which have been raised to the former automobile measure, the Governor permitted it to become a law without his signature.

NEWS OF THE LONG-PROMISED FRENCH CABS.

The gasoline taximeter cabs which the New York Transportation Company has solemnly promised to bestow on the city before the end of the year will be a mixed company, principally from the Delahaye and De Dion Bouton factories in France and the Maxwell works in this country. The first batch of nine Delahayes are expected to be here very shortly, and further consignments will arrive at monthly intervals. A number of these vehicles are at present in use in Paris and London. They are equipped with a four-cylinder 18-horsepower engine carried forward on a pressed steel frame, have three speeds forward and reverse, and shaft drive. A plain but elegant landaulet body, which can be completely open in summer, will be supplied with the machines by a Parisian body builder.

E. R. THOMAS TRIES OUT A VANDERBILT CUP RACER.

With George S. Salzman at the wheel, E. R. Thomas, the Buffalo manufacturer, put one of the racers he is building to annex the Vanderbilt cup, through its paces at Kenilworth Park near Buffalo on Memorial Day.

CLEVELAND'S HUSTLING CLUB IS BUSY.

CLEVELAND, O., June 3.—The Cleveland Automobile Club has made extensive preparations for its annual hill climb, to be held Saturday of this week on Gates Mill hill. The hill has been improved and graded to allow for high speed at all points. One point of advantage about this contest is that there will be no long waits and the contests will be run off in rapid succession. This is possible owing to the fact that the cars do not return by way of the hill, but run back to the starting point by another route.

Steam cars will not be barred at Gates Mill, as they were at Wilkes Barre, and in the open events, as well as in the price classes, they will be permitted to compete against the gasoline cars. There will probably be two or three special events for electric, as two or three makers have expressed their intention of entering cars of this type.

The touring committee of the Cleveland Automobile Club has arranged for a club tour, July 3 to 10, inclusive, to Watkins Glens, N. Y. The route selected by the committee is through Buffalo, Dansville and Bath, passing the New York State fish hatcheries near Hammondsport. The run is about 800 miles round trip over some of the best roads in this section of the country. The tourists on Saturday and Sunday will be the guests of the Seneca Yacht Club.

The Cleveland Automobile Club has secured within \$5,000 of the amount needed to complete the model road, which the club proposes to build on the Euclid road between East Cleveland and Wickliffe.

The Cleveland Automobile Club has appointed a committee to devise ways and means for the entertainment of the A. A. A. tourists who will congregate in Cleveland a day or two before the start of the tour from Cleveland, July 10. This committee consists of George Collister, Walter C. Baker and Asa Goddard.

RUNS OF THE MINNESOTA ASSOCIATION.

MINNEAPOLIS, MINN., June 3.—An endurance run will be held under the auspices of the Minnesota State Automobile Association late in July, if present plans materialize. The affair will be known as the "Little Glidden Tour," and the route will be between the Twin Cities and Superior, Wis., and Duluth, Minn. Frank M. Joyce, president of the Minnesota Association, has been over the proposed route and believes it to be a splendid route for such a test. In places there is enough sand to make the best of machines show the mettle they are made of.

The first tour of the Minnesota Association will be held June 22, when a run from St. Paul and Minneapolis will be made to Mankato, where the quarterly meeting of the Minnesota body will be held. On the way down the route will include the towns of Shakopee, Jordan and St. Peter. The return will be made via Waterville, Faribault and Waseca. The distance each way is 125 miles. The trip will be in charge of George H. Daggett, chairman of the State Touring Committee, and a member of a like committee of the National Association.

CARS WANTED FOR NEW YORK ORPHANS.

Automobilists of the Metropolitan district who want the opportunity of doing a most kindly act have an eleventh-hour chance by notifying S. A. Miles, No. 7 East Forty-second street, that their cars are at the disposal of the Orphans' Day Committee of the New York Motor Club, whose event will take place on Wednesday, June 12. Though the club has obtained over a hundred cars, it needs at least a score more in order to provide for the generous number of orphans which it hopes to entertain by a ride to Coney Island, a visit to the wonders of Dreamland, and a feast that will be appreciated by many hungry little mouths. Therefore, after reading this appeal, notify Mr. Miles at once by letter or telephone—his telephone is 4868-38th—that your car is available bright and early on the morning of June 12.

ENTRIES FOR SEALED BONNET CONTEST.

Routes for the four-day contest to be held under the auspices of the Automobile Club of America on June 19 to 22, inclusive, having been decided upon, the contest committee and the Bureau of Tours are busy surveying and preparing road directions. Four different routes of 150 miles each have been selected. The first day's run is along the Hudson to Poughkeepsie and return; the second up the Harlem valley, through White Plains, Mt. Kisco, Pauling and return; the third along the Sound to West Haven and return, and the fourth to Bridgeport, returning via Danbury, Pauling and the Harlem valley, as on the second day. The high-powered runabouts will have to travel twenty-five miles more per day than touring cars in the same class, but will follow the same routes, with the additional run to cover each day.

Fourteen cars have already been entered in two classes, those in Class A, composed of cars selling for more than \$3,000, being the American Locomotive Company, one Berliet touring car; Lozier Motor Company, two Lozier touring cars; Locomobile Company of America, three Locomobile touring cars; Wyckoff, Church & Partridge, one Stearns touring car. In Class B, which includes all cars selling between \$1,500 and \$3,000, the following have been entered: George J. Scott Motor Company, one Glide touring car; A. M. Day, one Elmore touring car; Locomobile Company of America, three Locomobile touring cars; Atlantic Motor Car Company, one Stoddard-Dayton touring car and one Stoddard-Dayton runabout. The entries will close with the contest committee at the clubhouse on Wednesday, June 12.

BUFFALO CLUB AFTER COUNTRYHOUSE.

BUFFALO, N. Y., June 3.—The Buffalo Automobile Club is negotiating for the purchase of the Larkin homestead on the north end of Lock street in the city of Lockport. The property is owned by Henry Steiner, but the club, it is said, desires to have the place remodeled and used for club runs from Buffalo to Lockport over the new Transit Road. The consideration asked is in the neighborhood of \$10,000. The house is a handsome one on the colonial style, situated on a high ridge, and overlooks the vast plain extending to Lake Ontario.

Fifty new members to the roster of the Automobile Club are expected to be added soon. That number of applications was received up to yesterday, and it was only a month ago the members elected sixty-six new automobilists.

President White has appointed a committee of ten from the club membership to serve as special police officers. The committee will be sworn in this week by the Police Commissioners.

DETROIT TO HAVE SEALED BONNET EVENT.

DETROIT, MICH., June 3.—June 15 is the date set by the Detroit Automobile Club for the first extended run of the season, at which time a 100-mile non-stop contest will be pulled off. Starting from this city, an angling course will be followed, the race ending at the club's quarters at Pine Lake. Prizes will be awarded the winners in the three classes established, one division being for cars weighing over 3,000 pounds, another for those between 1,500 and 3,000 pounds, and the third for those under 1,500 pounds. All hoods will be sealed and wired before the start, and no repairs, adjustments or replenishments of any kind, save tires, will be permitted. Entries are coming in at a rapid rate, and a spirited contest is promised.

SCHOOLEY'S MOUNTAIN CLIMB ON JULY 4.

It is practically arranged that there will be a climb of Schooley's Mountain, N. J., on July 4, and conducted under the management of the energetic W. J. Morgan, who has secured permission for the holding of the contest, which will be limited to stock cars. Schooley's Mountain is about fifty miles from Newark, and within five miles of Hackettstown. The course will be about 1½ miles, and the mountain road will be extensively repaired.

JERSEYMEN ORGANIZE GARAGE ASSOCIATION.

ASBURY PARK, N. J., June 3.—Automobile dealers in this vicinity have organized the Seashore Garage Association, with headquarters in this city, for the purpose of equalizing garage and charging rates and formulating a uniform price list for supplies and accessories. Membership will be sought with the New York association.

At a meeting in Eagle Hall last week the association was formed, representative automobile men from Lakewood, Spring Lake, Belmar, Long Branch, Elberon, Deal, and Asbury Park being present. C. R. Zacharias, of Asbury Park, was elected chairman, and Robert W. Boone, of this city, secretary. A committee consisting of Charles Keene, of Deal; Mr. Strummel, of South Elberon, and J. H. Johnson, of Spring Lake, was appointed to formulate a constitution and set of by-laws. A committee on rules consists of Joseph B. Hoff and John H. Aaring, of Lakewood, and E. J. Harrington and Mark Guy, of this city. A banquet followed the meeting.

AMERICAN NAPIER COMPANY REORGANIZES.

Under date of June 3 the incorporation of the Napier Company of America in Boston is reported. No facts or figures as to the details of the reorganization of the company that has been building Napier cars in this country for several years past, and which recently went to the wall, are made public, other than the bare statement that the company has been incorporated with this title under the laws of Massachusetts. The capital is \$200,000 and the officers are: President and treasurer, Otto B. Cole, Boston; clerk, Hugh W. Ogden, Brookline. The only apparent connection between the new regime and the old is to be found in the fact that Mr. Ogden figured as attorney for Vice-President Farnsworth of the old company, who was appointed its receiver in bankruptcy. The former concern was known as the Napier Motor Car Company of America, and was capitalized at \$600,000, but whether it ever made or sold any cars, except in the immediate vicinity, does not appear.

TWENTY-NINE IN ONE DAY 200-MILE TEST.

At 6 o'clock this morning the first of the twenty-nine cars engaged in the New York Motor Club's 200-mile run was sent away along the Hudson river road to Poughkeepsie. The others followed at intervals of one minute. From Poughkeepsie the route of the run is through Millbrook, Amenia, and Lakeville, to the Berkshire Hills, and then via Salisbury, Great Barrington, and Lenox to Pittsfield. From this point the course is eastward to Chatham, thence northward to Albany. Following is a list of the competitors in the order in which they were started:

1. Prayer-Miller, H. H. Knepper; 2. Corbin, James Swan; 3. Dragon, John Haynes; 4. Stoddard-Dayton, Ray Howard; 5. Knox, H. M. Davis; 6. Mora, F. Cimdrott; 7. American, H. E. Trevor; 8. Continental, C. S. Johnston; 9. Lozier, H. Michner; 10. Welch, E. L. De Camp; 11. Haynes, C. B. Warren; 12. Pope-Hartford, Phil Haines; 14. Berlet, P. J. Johnson; 15. Pope-Toledo, Joe Judge; 16. Stearns, W. I. Flickling; 17. Premier, C. C. Singer; 18. Glde, J. C. McCafferty; 19. Franklin, R. G. Howell; 20. Pierce, J. S. Williams; 21. White, R. B. Mann; 22. Aerocar, A. M. Robbins; 23. Maxwell, Chas. Fleming; 24. Corbin, John Dower; 25. Mitchell, E. W. Hudson; 26. Stoddard-Dayton, R. Newton; 27. Dragon, A. L. Kull; 28. Darracq, S. B. Stevens, Jr.; 29. Corbin, Jim Corbett; 30. Reo, B. L. Luckwood.

BAKER ELECTRIC PASSES CENTURY MARK.

CLEVELAND, O., June 3.—The Baker Motor Vehicle Company has never made any very great claims for high mileage radius of its electric vehicles, but last week, to satisfy a doubter, the Price Brothers' Carriage Company, Cleveland agents for the Baker, made a test run with a standard Baker victoria fitted with a standard Exide 9 m.v. 24-cell stock battery, a car which had been in continuous service for four months without attention, and covered 101.6 miles with one charge. Much of the run was over unpaved streets and a number of grades were encountered.

DETROIT'S AUTO PLANTS ARE STILL BUSY.

DETROIT, MICH., June 3.—The lassitude usually making its appearance at this season of the year in the automobile industry, and which increases as the summer months advance, is little in evidence among Detroit plants. On the contrary, unwonted activity is to be found in a majority of instances. Several reasons may be given for this condition of affairs. That there will be more cars than ever before marketed in a single season has been determined beyond a question of doubt. At the same time, the backward spring has held up shipments to an appreciable degree, the man who contemplates purchasing a car preferring to wait until the weather offers some inducements to motorists.

Nor has this proved an unmixed blessing. Far-sighted manufacturers were quick to note the changed conditions, and governed their course accordingly. Heretofore a majority of the local plants have been forced to run nights for a portion of the time to meet the rush. This season there has been little or none of this overtime work, the even trend of affairs permitting that attention to every detail that is so essential in the production of a high-grade automobile. The additional expense incurred in working longer hours has been eliminated, the factories have operated steadily to date, with the prospects encouraging for a continuation of activities taking the place of the customary spasmodic spurts, followed by a dull period, and from every standpoint the situation is regarded as much more encouraging than was the case even a few weeks earlier.

RUSHMORE TO HAVE UNIQUE POWER PLANT.

After having constantly extended its old plant until there was no ground left to expand further, the Rushmore Dynamo Works has found it necessary to have still more room and have broken ground for new buildings, the main one of which will be 250 by 50 feet, two stories high. Though the addition is to be of the most advanced type of modern factory construction, interest centers in the new power plant. It is a type more or less well known in Europe, but this is to be the first of its kind here, at least in connection with the automobile accessory business, and the town of Plainfield, N. J., where the plant is situated, will take on new interest by reason of its location there.

The power house, which will be a separate building, measuring 50 by 50 feet, will contain a 200-horsepower, twin-cylinder horizontal Koerting gas engine, direct-connected to a large generator, the drive throughout being electric on the group system, except in the case of heavy units, which will be direct-driven by electric motors. The engine and generator unit will weigh in the neighborhood of 80,000 pounds, and there will be a similar 75-horsepower unit for use in emergencies and to take care of occasional overloads, the plans including provision for a duplicate of the large unit in the future. A ten-ton electric crane will span the engine room and will facilitate the installation of the machinery as well as its handling when repairs are needed.

Gas will be supplied by two anthracite producers, one of 250 horsepower and the other of 75 horsepower, the gas also being used for heating the furnaces of various kinds used in the plant, while the buildings will be warmed by a forced hot-water circulation of the cooling water from the engine jackets. The temperature of this water will be raised considerably by being passed through a special form of boiler utilizing the hot exhaust gases direct from the engine. There will also be a complete brass foundry, measuring 50 by 50 feet, and as it is the intention to run both the old and the new plants at full blast, they will be connected by a light gauge railway running through all the departments.

The new power plant is calculated to effect an economy of three-fourths the coal ordinarily required to run the same amount of machinery, and as lens grinding calls for a great deal of power, there will be a great reduction in the cost of manufacture. The complete factory will represent an investment of \$100,000 and will be the most elaborate of its kind in the world.

BRIEF ITEMS OF NEWS AND TRADE MISCELLANY

Mrs. H. A. Lozier will drive her Lozier car in the Orphans Day parade, to be given under the auspices of the New York Motor Club, June 12.

The Tuxedo (N. Y.) Park Association is now running a line of auto 'buses from its clubhouse to the railway station. Seven cars are in service. Charles Allen, formerly with the Maxwell-Briscoe Company, has charge of the cars and the garage.

A 40-50-horsepower six-cylinder Rolls-Royce car is to take part in this year's A. A. tour for the Glidden cup, one of these cars having been ordered from the Rolls-Royce Import Company, of New York, by a customer, expressly for this purpose.—*The Automotor Journal* (Eng.)

French papers received state that all the winners in the Targa-Florio Cup race abroad, which included the Fiat, Itala and DeDietrich, were equipped with Truffault-Hartford shock absorbers, which are now included as regular equipment on seventeen different makes of cars sold in this country.

York (Pa.) automobilists are interested in a novel event which is now well underway for a twenty-four-hour non-stop contest which is to be held during the latter part of July. James A. Kline, general manager of the York Motor Car Company, manufacturers of the Pullman automobiles, is one of the originators of the run, and plans are now being completed.

A line of coupés, especially for the use of physicians, is nearing completion in the Winton factory at Cleveland. The body is modeled after the coupé that Mr. Winton has had in his personal service for more than a year. The body encloses the steering wheel, the dash and its equipment and the seats, affording the fullest protection from the weather to driver and passenger.

An interesting test of carrying thirteen passengers up Corey hill, Boston, was made in a 20-horsepower Maxwell touring car, May 11, and gave to the Ajax tires, with which the car was equipped, a pretty tough proposition to handle, from which they emerged with flying colors. The tires were 30x3 I-2, and the whole outfit weighed over two tons. The distance was 500 yards, on a grade varying from 12 to 18 per cent.

May was another record-breaking month for the registration of automobiles at Albany, there being 2,209 registered during that period. Of this number, 172 were imported cars. The leader in registrations was Ford, there being almost twice as many of that make registered as any other. The total of Fords were 222. Next in order comes the Cadillac, with 143, and close to it the Maxwell with 140 registrations.

The new form B odometer of the Veeder Manufacturing Company is not equipped with trip indicator, as would be inferred from a perusal of a notice concerning same that appeared in our issue of May 16, page 841. Its new feature is a simplified universal attaching fixture, so made that any owner can readily adjust the fittings to his own car. Veeder instruments show total mileage up to 10,000 miles, and some models also show the separate distance of each

trip, the trip figures being reset to zero before the start without disturbing the totals.

The White Company has just issued the third of its series of route books, which are for free distribution to all tourists. This new issue is devoted to the main touring route between New York and Boston. Complete and accurate road directions are given for traveling over this important route in either direction. The route directions are copiously illustrated, and, in addition, there is a fine double-page map. Copies of White Route Book No. 3, and of the two previous issues, may be obtained on application to The White Company, Cleveland, Ohio, or to any of its branches or agencies.

Ohio's town, "where the rubber tires come from," which everyone knows means Akron, is as progressive as its tire makers, for it has had an automobile patrol wagon for the past eight years. The latter was a pioneer in this field, as it was the first of its kind in the country. Now it is about to be supplanted by something more modern in the shape of a Reo 16-horsepower gasoline car. The order was awarded to the Reo Motor Car Company, of Lansing, Mich., through their local agent, M. S. Long, at Akron, and the chassis is being built according to specification. The body will be that ordinarily employed on the Reo 'buses and will have a seating capacity of ten people.

The Salisbury Wheel & Manufacturing Company of Jamestown, N. Y., has issued invitations for its second annual house party and outing, which will be held in the Lakewood Country Club at Lakewood, on Chautauqua lake, during the week of June 29-July 6. The invitations have been sent to the patrons of the company and to automobile manufacturers and others interested in the business. The members of the "Steering" Committee are Clare A. Pickard, Scott H. Penfield, Erwin D. Shearman and Fletcher Goodwill, all good entertainers. The program will include fishing, boating, motoring, steamboat trips and the Country Club golf links will also be at the disposal of the guests during their stay.

In the description of the Auto-Light which appeared in THE AUTOMOBILE of May 2, it was erroneously stated that this device, which is a clever and simple arrangement for lighting the lamps from the seat, was used in connection with the ignition system of the car. The makers state that this is not the case, as two years' experience in so using it has demonstrated beyond any question that such interconnection does not give satisfactory service, one of the reasons being that the average autoist is prone to blame the Auto-Light for trouble arising in the ignition system, even where nothing more serious than a sooted plug is at fault. Consequently, they have made the device entirely self-contained; it consists of the sparking attachment for the burners, a small dashboard coil with an ingenious switch, and the necessary primary and secondary connections. To light the lamps, the gas is turned on and the switch moved first to one point and then the other, an automatic attachment preventing a short circuit in case the driver should omit to

open the switch after both lamps are lighted, so that there is no danger of ruining the batteries by permitting the sparking to continue at the points when the operation of lighting is completed.

Headed by Pierce Schenck, of the Dayton Malleable Iron Company, of Dayton, O., a company has been recently organized to give Dayton its second automobile manufacturing plant. Mr. Schenck is one of Dayton's pioneer autoists, and is considered quite an authority on automobile construction. The new company has acquired four acres of land, together with the factory of the Dayton Machine Tool Company, at Edgemont, and will devote its attention to the manufacture of both six and four-cylinder cars, but particularly the former. The Rutenber motor will be used. The title of the new concern is to be the Speedwell Motor Car Company, which was incorporated last week with a capital of \$50,000, the organizers being Pierce Schenck, H. C. Barnes, J. A. McMahon, J. Sprigg McMahon and B. B. Etter, all of Dayton. It is intended to only turn out a few cars this season, but preparations will be made for a large business for next year.

RECENT TRADE REMOVALS.

The Boston Gear Works has removed to its new and commodious factory at Norfolk Downs, a few miles south of the Boston city limits, where ample facilities for its largely increased business are to be had. The Boston office and storage facilities at 102 High street, corner Congress street, are retained.

The C. G. V. Import Company is now permanently located in its new building, 1849 Broadway, at Sixty-first street, New York City, where ample space permits a fine display of cars. The garage and storage facilities enable the company to import C. G. V. cars in such numbers that immediate deliveries can be made customers. A reception room for customers adjoins the offices on the second floor.

NEW AGENCIES ESTABLISHED.

The Capitol Hill Garage, 615 B street, Southeast, Washington, D. C., operated by James J. Flynn, has been appointed agent for the Rambler and Mitchell cars in that city.

H. T. Cruger has been appointed agent for the Ford at Waco, Texas. He is located at 615-17 Franklin street, having purchased the plant and salesrooms of the Banning Machinery Company, which he succeeds.

The J. Stevens Arms & Tool Company, of Chicopee Falls, Mass., will open a branch store in Boston for the sale of Stevens-Duryeas next season. This car has been represented at the Hub in the past by the late F. E. Randall.

Among the new agencies recently established by the Rainier Company is one for the State of Texas, in charge of H. H. Lewis, Jr., who will be located in Fort Worth and who will be the first agent to take on the Rainier cars in this territory.

The Wayne Motor Company is the style of the new concern which will handle the Wayne cars for Chicago and

vicinity. The company is composed of Chicago men, and Otis Friend, formerly with the Chicago Mitchell agency, has been appointed manager. Space has been leased from the Branstetter Motor Company, at 1337 Michigan avenue, where headquarters will be made. Jesse Draper, sales manager of the Wayne Automobile Company, of Detroit, recently completed final arrangements for the transfer of the agency from the W. W. Shaw Company to the new concern.

PERSONAL TRADE MENTION.

J. N. Merwin, sales manager for the Forest City Motor Company, Massillon, O., is visiting the eastern agents of the Jewel car.

R. B. Jacobs is to manage the automobile and accessories show which will be held at Foot Guard Armory, Hartford, Conn., March 23-28, 1908.

Chester E. Clemens, formerly connected with the Napier Motor Company of Boston, as designer and engineer, is now with the automobile department of the St. Louis Car Company, St. Louis, Mo.

Walter Clapp, Jr., formerly connected with the Boston Rambler branch, has accepted the position of manager of the Hartford Rubber Works Company's branch at Buffalo, entering upon his duties June 1.

S. H. Baker, who has been manager of the F. E. Randall estate, which represents the Stevens-Duryea in Boston, has resigned his position to enter the local trade as agent for a line of cars, as soon as he can conclude arrangements.

George H. Strout, of the sales department of the Electric Vehicle Company, of Hartford, Conn., is making a trip among the Columbia dealers in southern territory. He reports trade conditions in the cities he has so far visited as particularly encouraging.

Chas. G. Percival, for the past three years with the Linscott Motor Company, of Boston, has resigned and will enter the local trade in that city with an agency for one of the leading Western cars, the details of which will be announced later.

Mark C. O'Connor has been appointed purchasing agent for the Forest City Motor Company, Massillon, O. He was for several years with the purchasing department of the Waverley department of the Pope Motor Car Company, Indianapolis, and later with the Marion Motor Car Company, of that city.

C. S. Pelton, who has been with the B. F. Goodrich Company for the past five years—three at the factory and two at Pittsburg, Pa.—has been appointed manager of the Buffalo branch of the Pennsylvania Rubber Company. Fred Roblin, who has had charge of the Buffalo branch temporarily, will return to the tire department of the Pennsylvania company's plant, at Jeanette, Pa.

Charles Bates, for several years manager of the Frederick E. Randall estate agency of the Stevens-Duryea cars in Boston, who left that position last year to become superintendent of the Bay State Automobile Company, makers of the Bay State Forty, has just rejoined his old connections. Mr. Bates is an Englishman, and has long been identified with the automobile industry on both sides of the Atlantic, having been associated with the English Daimler Company before coming to Boston.

TWO NEW MOSLER PLUGS.

The makers of the "Spitfire" plugs, A. R. Mosler & Co., 163 West Twenty-ninth street, New York, announce that they are now manufacturing a line of plugs patterned after the recently adopted standard of the Association of Licensed Automobile Manufacturers. This is a 7-8 inch plug with 18 threads to the inch. They are also introducing two new plugs, to be known as the Mosler Triumph and the "Beat-M-All." Both are of the open-end type, with deep recesses, and have the same effective porcelain insulation as the Spitfire. Some idea of the extent to which the Mosler factory is being pushed is shown by its single order for 300 ounces of platinum.

THE "COLBURN SKYSCRAPER."

It was not so very long since that Colorado was not considered a particularly good place for automobiles, much less for manufacturing them, but conditions have changed and probably the State can now boast as many cars in proportion to its population as any other. This year she is going to turn out some of her own cars. The Colburn Automobile Company, of Denver, is to be the sponsor and the production is to be known as the Colburn Skyscraper. Unlike many of the projects that come out of the West, this is not of the usual gigantic proportions. The new company is modest—it is only going to set out to build fifty cars this year—but it is going to build them well. Next year it will do better on numbers.

The car is to be a four-cylinder 25-horsepower vehicle with a sliding-gear transmission, using the selective type of operation, and having four forward speeds, with the direct drive on the third. The motor is to have all the valves in the head operated by a single super-imposed camshaft; a duplicate system of ignition will be employed, using a high-tension magneto and accumulators.

The clutch will be of the conical type, with cork inserts, and the final drive will be by double side chain. Timken roller bearings will be employed on the running gear and D. W. F. ball bearings in the change-speed gearbox, the latter having chrome nickel-steel gears. With full equipment, including top, the car will list at \$3,250.

NEW TRADE PUBLICATIONS.

An illustrated catalogue from the American Motor Company, Brockton, Mass., presents a complete description of the Marsh-Metz motorcycle and its use as a tricar for pleasure or delivery purposes.

A terse talk on electric automobiles to those who know or want to know is the subject matter of a booklet published by Oliver P. Fritchle, under the title "What I Am Doing and Why." The publication, which deals with Fritchle electric vehicles, can be obtained from the firm's headquarters at 1449-1455 Clarkson street, Denver, Col.

In connection with the Jamestown Aeronautical Congress a handbook has been produced by the Department of Congress and Special Events, with offices at 12 East Forty-second street, New York, dealing generally with the aero section of the Jamestown exhibition. In addition it gives a complete list of officers, a list of the ascensions made in the United States by members of the Aero Club, a list of aeronautical prizes, etc.

From the Coppock Motor Car Company has been sent forth an illustrated catalogue of the Coppock model A one-ton truck driven by a three-port two-cycle gasoline motor. The application of the two-cycle to commercial vehicles offers a considerable amount of interest, and the booklet should be in demand among present or prospective users of automobiles for commercial purposes. It can be obtained from the company's headquarters at Marion, Ind.

The two-engine automobile manufactured by the Carter Motor Car Company, Detroit, Mich., has as its distinctive feature two independent gasoline engines, each having either two, four, or six cylinders, and each one capable of being used independently or together. There being always a complete power plant in reserve, the danger of being stalled on the road is entirely removed. Full particulars of the machine are to be found in the booklet just published under the title "Carter Two-Engine Automobile."

It is an interesting, racy monologue that is presented between the covers of the little brochure issued by the American Motor Car Company, with the title "Two in a Roadster." The writer has dropped the usual shriek of the advertising man, and tells his little story in a manner interesting to all, while the excellent vignettes on every page carry you along with him and give an additional interest to the narrative. Finally, if you are so disposed, you can study the make-up of the car around which the writer has spun his romance, in three or four pages at the end of the booklet.

"A Treatise on Marine Gasoline Engines" is more than an ordinary trade catalogue, for it comprises a lengthy description of the marine engine in general and the Ferro marine engine in particular. Of more than sixty large illustrated pages, it describes every part of the marine gas engine in detail and shows several of the processes of production. The book should be received with interest by all motor boat men. A smaller publication also from the Ferro Machine & Foundry Company, of Cleveland, gives detailed instructions for the care and working of Ferro marine engines. It is a practical, useful publication. These two books will be sent postpaid to any address upon receipt of ten cents.

"A Study in Graphite" is the title of a recent booklet published by the Joseph Dixon Crucible Company and one that will make special appeal to the inquiring mind. It gives in detail a series of tests of graphite made by Professor W. F. M. Goss, of Purdue University. These tests were not made with a view to finding points for or against graphite, but were conducted in the spirit of scientific research. The study opens with a dissertation by Prof. Goss based upon the conclusions drawn from the results of the tests. Then follow complete descriptions of the tests together with illustrations of the testing machine made from photographs and drawings. The condition of the bearings and journal is shown by photographs taken at different stages. A limited number of copies will be distributed free of charge to all those interested in the science of graphite lubrication. Address the Joseph Dixon Crucible Company, Jersey City, N. J.

INFORMATION FOR AUTO USERS.

Syracuse Storage Battery.—This storage battery, guaranteed for one year by the Syracuse Auto Supply Company, 118-120 State street, Syracuse, N. Y., is built upon standard accepted principles and em-

THE SYRACUSE STORAGE BATTERY.

bodies all the necessary requirements to make a light-weight, powerful and durable battery. The pasted type of plate, employing the reinforced staggard grid, is used. The active material is specially prepared to produce the highest capacity per pound weight. The cells are encased in a compact quartered oak box with hard rubber top and heavy nicked handles and guards.

An Automobile Tire Protector.—Manufactured by the Perfect Tire Company, Rock Rapids, Iowa, the cover here illustrated consists of steel plates two inches

"PERFECT" TIRE PROTECTOR.

wide, oveled so as to fit the tread of the tire, and lined with a belting which holds them together and comes in contact with the tire. The plates are wide enough to

protrude slightly over the width of the tread, the chains holding the plates to the tread barely touching the sides of the tire. These chains are held to the wheel by a band ring with turn buckles, so that it can be loosened or tightened at will. The cover can be taken off or put on in 15 minutes.

A Renewable-point Spark Plug.—The feature of the Wiley spark plug, manufactured by the Hub Lubricator Company, 78 Portland street, Boston, Mass., is that the point can be renewed by replacing the cartridge C by a new one, and by changing the point A. The plug is made of best selected mica, double insulated, and will

WILEY SPARK PLUG IN SECTION.

not short circuit. It is claimed that with this form of construction the Wiley is equivalent to two plugs and therefore an economical commodity that will commend itself to auto users.

Safety Steering Device.—After three years experience on high-grade cars, the Boston Gear Works of Norfolk Downs, Wollaston, Mass., offers a safety steering device of the worm-gear type. The worm is made of machinery steel, and the sector is of best quality drop forged steel, both case-hardened 1-32 inch. The casings enclosing the working parts are cast in two pieces, an upper and a lower, bolted together. They can be either cast-iron or a special hardened aluminum. Bearings are long and are made of bronze. When parts are screwed together large diameters and fine threads are used, making a strong and reliable connection. The sector shaft is of steel, and, if desired, can be made in one piece with crank. The bushings in which the sector shaft runs are eccentric.

allowing the taking up of any wear which may occur. The other adjustment, that of end play in the steering post, is also taken up by a nut on the bottom end of the steering post. The hanging of this device is a rather unique arrangement, the

WORM-GEAR SAFETY STEERING DEVICE.

sector shaft being made long and steel straps with bronze bushings holding the device in place. These supports can be made any length to suit conditions of car. By this method the device may be hung so as to give either a fore and aft or side motion of the crank.

Annable Pneumatic Auto-Spring.—Claims made for the Annable pneumatic auto-spring, manufactured by the Annable Pneumatic Spring Company, at Detroit, Mich., are that it will carry a car of any weight with as big a load as can be put into it on 13 pounds pressure to the square inch, compared with 70 pounds pressure for a pneumatic tire. The machine is suspended on air under slight pressure confined in cushions placed between the car body and the running gear. The four cushions are united by air tubes which admit of free play between each unit, and these are all connected to an air reservoir containing the same cubical volume of air and the same initial pressure as the cushions and tubes. Opening into this reservoir is a specially devised valve and a by-pass. When the cushions are violently depressed they are relieved of excess pressure by the air instantly passing into the reservoir through the valve, immediately afterwards returning to the tubes and cushions through the by-pass, but with graduated force.

Briscoe Radiator Reasons.—"Because on every order of any size we make duplicate working patterns and keep one set in each plant as insurance against fire, strike or breakdown; because we have our own brass foundry, our own machine shop; make our own tools, dies, tubes, etc.; because we have two plants, one east, one west, with duplicate equipment," and last but not least, "because we have studied radiators scientifically, experimentally and practically for the past seven years," are some of the reasons given by the Briscoe Mfg. Co., of Detroit, Mich.; and Newark, N. J., on their new mailing card just issued.

THE AUTOMOBILE

LOZIER WHICH GETS THE CUP IS TO BE SEEN IN THE FOREGROUND.

THERE were no ties in the 208-mile endurance run of the New York Motor Club. Judging from similar events which I have seen in France and Britain, this one-day contest from New York City to Albany via the Berkshires was the most strenuous thing of the kind that has been asked of the automobile since it appeared on the scene. The route embraced roads of all degrees, excellent, good, indifferent, and wholly bad; level stretches, and hills to climb and hills to descend, and, for a good share of Thursday, June 6, the rain descended upon the just and the unjust and the automobilists.

At the conclusion of the long, hard day, the one which survived with less points charged against it was a sturdy four-cylinder air-cooled Corbin, driven by John Dower; but, alas for its claim on the touring car class cup, it had come the latter part of the journey with one passenger less than the rules called for. Therefore, it was the ponderous Lozier, with H. Michener, at the wheel, which profited by the non-observance of the conditions.

In the runabout division the most consistent performer turned up in the Haynes, guided by C. B. Warren, and next best was Richard Newton's Stoddard-Dayton.

Considering the roads and the weather, and the extraordinary conditions that ex-

isted, the score of the day reflected to the rare ability of the automobiles participating, for 13 of 17 touring cars and 4 of 10 runabouts completed the trying trip; not to forget a half-dozen free lance official and press cars which reached the Ten Eyck in Albany before midnight.

Twenty-seven candidates in all responded for the fray and reported to Chairman R. H. Johnston—who deserves great credit for his masterly handling of the affair—and at 6 o'clock from the corner of Broadway and Sixty-second street the first car, a Frayer-Miller, took the word from Starter Wagner and Timer Dieges. A minute apart they were sent away, and in their wake followed the Berliet press car, of which I was one of the six occupants.

We thought we were law-abiding, but just as we tried to leave the outskirts of Yonkers there flashed past us on the deserted roadway—unoccupied except by ourselves—a “bike cop,” who haled us back to a station-house a mile or more away. Ser-

geant Cooley was gruff but sensible, and over the telephone Judge Beale recognized the technical character of the arrest. But when we took to the road again we were hopelessly in the rear and remained so nearly all day.

For twenty miles there was nothing, except the two official flags, to indicate an endurance test. The roads were muddy—

but they are often muddy in the neighborhood of Paris—and would surely improve when the vehicular traffic of the great city had been thoroughly shaken off.

Tarrytown hove in sight, there was a passing word with the checker, and the Berliet continued its regular easy, forward march through mud and rain.

Cold Spring, the second checking station, failed to bring any sight of the contestants, and it was somewhere in the neighborhood of Poughkeepsie that the rear guard was first overhauled. Continental was having trouble with tires, Frayer-Miller had a similar malady, and Dragon, Stearns, and Franklin were observed in difficulties of a like nature.

At Poughkeepsie, where, being non-contestants, it was possible to spend a few minutes to supplement the morning sandwich with more substantial refreshment, news was available of the group ahead of us. Maxwell had retired to the hotel garage to repair a cracked frame, and sent out a bulletin that she would soon be strengthened up and on the road again. Glide had slipped out for some unknown reason. Franklin was working furiously on tires—detachables, fortunately. Dragon, Stearns, and Continental came and left while we were waiting.

Outside Poughkeepsie there is a highway—highway is employed euphonistically—that no adjective in Webster's dictionary adequately describes. Had it not been so wet it might have been described as a plowed field; the only comparison which could be brought to mind was an oozy harbor, in a small town of boyish memories, which ran dry at low tides. The harbor bed, however, had a comparatively smooth surface; the Poughkeepsie road, on the other hand, was furrowed in a thousand lines, which held the wheels in a firm grip and prevented any deviation for the greasy path of rectitude. Fifteen yards ahead was the Continental, with a pressman-observer occasionally on its rumble seat. From left to right, and from right to left, the five in the tonneau of the Berliet bumped and jostled one another, soared upwards from one to twelve inches, and came down with pains varying from the minute to the acute. Not even the satisfaction of a unique experience was ours, for if some day in the chauffeurs' cafés on the Avenue de la Grande-Armée we dare to relate that a bunch of American machines traveled at over twenty miles an hour over roads compared with which the artillery drill ground in winter is a boulevard, we should be unceremoniously hooted out.

Little by little the belief that the Motor Club Committee had chosen a few of the least traveled tracks of the country as a special test of the machines began to slide away. They might have chosen fifteen or twenty miles of rocky riding; they might even have found thirty miles of it, but to believe that they would deliberately select the whole course over by-paths was impossible to believe. These must be the American roads we often read about in European journals, and around which returned travelers delighted to weave fancy flights of the imagination—invariably received with the remark *blague* and *bluff américain*.

At Great Barrington, 134 of the 200 odd miles, Pope-Toledo, Glide and Maxwell were the only three having disappeared from the mad mud run. Welch, Haynes, Aerocar, Corbin and Reo had perfect scores, at any rate so far as time on schedule was concerned. An average of about twenty miles an hour on such road conditions, where the engine plowed the machine through the most persistent mud it is possible to imagine, and where speed had to be kept very low in the occasional spots where speed was possible, owing to the operation of traps, is a performance of more than ordinary worth.

After lunch a readjustment of weight was made, the writer being transferred from Berliet press car to Berliet patrol car, the driver of which latter had no intention of remaining long in the rear. At the risk of being considered a dissatisfied grunter, one more mention must be made of the lack of roads. It was outside Lenox, splendid country, magnificent residences, every indication of material comfort, but between the two widely separated hedges a miry, slimy mass of the consistency of carpen-

ters' glue, rather more liquid and a little darker in color than the mother earth in the adjoining fields. On low gear and with wide open throttle the Berliet plunged into it as she had been doing for the previous six or seven hours. The running boards were under, the gasoline tank was reposing on the soft, greasy bed, half the radiator was choked with mud, the rear wheels spun round, and the car remained as immovable as a rock. Only when all passengers had been disembarked and the engine raced until its water was boiling could traction be obtained. When the spot was passed somebody discovered that the confetti car had passed over the footpath.

There was another similar experience after some delightful scenery in the Berkshires, when the Berliet struck a short, stiff grade with bottomless mud, a few miles from Chatham. Again she was lightened, this time of only half her crew, given a supply of water inside and outside the radiator, and rushed to the top. On the good portions—the good portions in this case being the stretches of road with an under surface covered with an average of not more than four inches of mud—there was exciting going. With a splash the front wheels would strike a muddy lake, throwing the brown fluid right and left with much the same effect as a motor boat taking a sea at high speed. Despite the wind shield, much of it came inboard, completely disguising the more exposed occupants at the end of a few miles. When one car passed another, a rather rare occurrence, the crew of the slower machine had to duck to avoid a shower.

Grade Crossings Caused Anxiety Throughout.

Few stops were observable for mechanical troubles. Tire annoyances were plentiful. Early in the day the Frayer-Miller was begging inner tubes from passers-by, the Franklin filled its tires with punctured tubes instead of air, and quite a number reported their fifth or sixth blow-out. Our own came soon after Valatie, while running for Albany in the dark. Almost at the same spot lay Franklin, abandoned, with rear axle disabled as result of running on flat tires. Further ahead lay the remains of the Corbin No. 2, whose sad accident was the only blot on an otherwise perfect tour. An entirely unprotected crossing—the Railroad Commissioners say it is one of the worst in New York State—the only wonder is that accidents of this nature are not more frequent; until the railroad companies are under the same obligations as other users of the highways, it is to be feared that other occurrences of this nature will have to be recorded. It was saddening news to learn of the death of poor Clarence McKenzie, a fatality that came so close to the end of the hard run.

Limping on three tires, the punctured pneumatic having come off en route, the Berliet checked in at Hotel Ten Eyck at a late hour. There was not a clean score, nor a clean traveler, among the 27 starters, but there were numerous exhibitions of mechanical endurance and human dash and skill of the superlative degree.

Summarized, the result of the New York Motor Club's 200-mile, one-day run is to be found in the table below. Controls were at Tarrytown (23 miles), Cold Spring (52), Poughkeepsie (75), Amenia (102), Great Barrington (134), Pittsfield (155), Chatham (183), and Albany (208).

For checking purposes each section of the route was considered independently, whatever their position, all cars starting out from controls free of penalty for that section. One point per minute for late arrival at controls, and two points a minute for repairs and adjustments, or early arrival, constituted the penalty list. Class A comprised full touring cars with not less than four passengers, and Class B included runabouts with either two or three passengers.

THE OFFICIAL REPORT OF THE COMMITTEE.

The Endurance Run Committee consisted of R. H. Johnston, chairman; S. B. Stevens, Jr., A. G. Batchelder, Alfred Reeves.

HAYNES, WINNER OF RUNABOUT CLASS, ON ARRIVAL IN ALBANY.

WHITE TACKLES A BERKSHIRE ROAD IN PROCESS OF REPAIR.

LAKEVILLE, CONN., WAS HAZY IN THE FALLING RAIN.

OFTEN ROADS WERE GREASY AND SKIDDING UNPOPULAR.

BERLIET "PRESS" CAR CAPTURED BY A YONKERS "COP."

"The award of the prize in the touring car class is made to No. 9 Lozier. The award of the prize in the runabout class is made to No. 11 Haynes.

"The observers' cards show that no adjustments, repairs or replacements were made to the following cars:

"No. 1 Frayer-Miller, No. 8 Continental, No. 9 Lozier, No. 11 Haynes, No. 12 Pope-Hartford, No. 14 Berliet, No. 24 Corbin and No. 26 Stoddard-Dayton.

"The remaining cars which finished received only minor penalties, which, it is reasonable to assume, might not have been necessary under normal touring conditions."

HERKOMER WON BY LADENBURG OF MUNICH.

FRANKFORT, GERMANY, June 11.—This year's Herkomer Tour, which has been on since June 5, was completed to-day, a Munich entrant by the name of Ladenburg being declared the winner. Out of the 161 starters, no less than 110 went the entire distance in good shape. The start was from Dresden around an 1,800-kilometer circuit, with the finish at Frankfort, and the event was purely an endurance run.

and W. J. Morgan. Monday night it completed the report of the run, and the following is included:

"In reference to the protest filed by the Welch Motor Car Company against Corbin No. 24, the committee find that the Corbin carried but three passengers from Great Barrington to Albany. The committee realize that there were extenuating circumstances in reference to the dropping of the original passengers and to proceeding thereafter with but three. Nevertheless, despite the fact that the Corbin finished with the least penalization, the committee have no other alternative than to declare it ineligible for the first prize. The protest entered by the Welch Motor Car Company against No. 9 Lozier has been withdrawn.

"The committee has also seen in the newspapers what purports to be a protest from A. G. Southworth. As no such communication, with the requisite fee of \$10, has been received by the committee, it would not have been necessary to take any cognizance of same, except that it implies that the committee was not fair to No. 12 Pope-Hartford. In answer to this allegation it is only necessary to point out that had the car in question adhered to its schedule it would have been due at Albany at 6:11. As a matter of fact, it did not arrive until 8:22, which obviously and unquestionably entailed a penalty of 131 points, as the most superficial examination of the rules would show.

GRADE CROSSINGS ARE A MENACE TO AUTOMOBILES.

WEATHER SPOILS BRITISH TOURIST TROPHY RACE

By JOSEPH F. MACKLE.

DOUGLAS, ISLE OF MAN, May 31.—The patriotic autoist has another cause to rejoice, for now a third time an all-British car has carried off the Tourist Trophy. Success this year has rewarded the Rover, the production of the old Coventry bicycle firm, which now achieves its first victory in automobile racing. Second place has fallen to the Beeston Humber car, while

CURTISS IN WINNING ROVER ROUNDING WILLASTON CORNER.

no third competitor managed to finish the course. Such a statement must seem disappointing; in reality it is the weather and not the cars that must be held responsible.

Altogether 31 entries were made for the race compared with 43 last year, and even this small list was much reduced by withdrawals. Rolls found himself unable to defend his position as holder of the trophy and no less than six other cars were not completed in time. Of these the greatest disappointment was created by the absence of the new British-built Mercedes, which was to make its first appearance at the race. The remainder, small as it was, looked likely to be further reduced by some bad smashes which occurred during practice, but luckily replacements were effected in time and no further retirements were rendered necessary.

The principal condition of the race limited the fuel allowance to a gallon of gasoline for every 25 miles of road. This is, of course, the fundamental idea of the Tourist Trophy races and that it is a suitable method of preventing unduly high engine power without limiting too much the scope of the designers is seen in the adoption of this same principle in the Grand Prix race. Further latitude was this year allowed by the abolition of chassis weight limits, but an increase of the total load from 1,200 to 1,400 pounds has made the task somewhat more difficult. This load was in many cases made up by the use of cast-iron floor boards and by nailing sheet lead to the tonneau seats, and in view of the big dead weight it was significant to note that spare springs were being carried on many of the vehicles.

How the Contestants Were Examined.

The cars were assembled at the enclosure on Tuesday morning and much interest was aroused when the closing hour arrived, in view of last year's fiasco, when no less than six cars were disqualified through arriving a couple of minutes too late. Promptly at 10 o'clock the gates were closed, and almost immediately the Leader car—false to its name—came gently down the road. As this was the lowest powered car in the contest, some unkind persons suggest that the disqualification was intentionally gained. Inside the enclosure the cars were marshaled into line and, with observers on board, the procession led off to Quarter Bridge, where a level half mile had been marked off for the slow run on top gear. All successfully covered the distance at less than the specified twelve miles an hour, but the spasmodic jerking of some of the cars clearly showed the lack of flexibility of a high

geared high compression engine, with a carbureter finely adjusted for economical running. The other gearing test consisted of a stop and start on a 1 in 6 grade, but this was quickly disposed of without any trouble. Back at the enclosure the technical committee officials set themselves to the monotonous task of weighing up the cars and ballast, and seeing that the many and unnecessary regulations covering the body and chassis dimensions had been carried out.

Actual Stock Cars Mostly Utilized.

Observation of the cars ranked in long line in the tents revealed that the freak type of car was much less in evidence than at previous events. In many cases actual stock cars were utilized, with, of course, specially tuned up carbureter and higher gearing. The remainder had been specially built for the event, but were on the maker's standard lines and easily recognizable. The engines showed a tendency towards long strokes, and at the same time the compression had been raised to the highest possible figure. Carbureters seemed to afford the biggest scope for individual effort, and in nearly every case some special arrangement was incorporated in the design. Almost always the automatic air device was replaced or assisted by a hand-operated extra air inlet, and the new Gillet-Lehmann carbureter controller was found on five cars, the opinion of these drivers being that the device showed good saving.

The transmission gear was mostly devoid of novelties of construction. The direct drive on third speed and indirect fourth has naturally retained its popularity in an event where so much downhill rushing is required, but in one case, the Hillman-Coatalen car, this practice has been adopted with three speeds, the direct second giving up to forty miles an hour and being normally in use while on favorable grades, the indirect third taking it to

HUMBER (READ) AT BOTTOM OF KIRKMICHAEL DIP.]

MILLS IN BEESTON-HUMBER LEAVING HILLBRON.

J. P. HUTTON IN HIS BERLIET GOING WELL.

almost seventy miles an hour. This is well worth consideration for touring car work in view of the saving in length and complication in the gear box. As might be expected from the comparatively low power of the engines, shaft drive easily comes first in favor, side chains having but few adherents.

Wire Wheels Much in Evidence.

Perhaps the most interesting tendency to be noted is the general use of the wire wheel, fourteen cars out of twenty-two having adopted this practice. There can be no doubt as to the superiority of the wire spoke wheel for racing purposes and the absence of serious accident in spite of the constant serious side slips during the race must in great measure be due to the big lateral strength of this type of wheels. The majority of the wire wheels were of the detachable type just introduced by the Rudge Whitworth firm, a spare wheel complete with tire being put on inside of one minute. The few cars with wooden wheels had all removable rims. The examination and weighing in was not completed until Wednesday afternoon, and the measuring out of the allotted quantity of fuel had to be rushed through in order to finish before daylight failed.

Began in a Steady Downpour of Rain.

All previous racing events in the island have been favored with the best of weather, but at an early hour yesterday morning the weather conditions indicated a big change. A steady downpour of rain greeted the commencement of operations at 8 A.M., at which hour the cars were drawn out by horse to the adjoining hill leading down to the course. The roads were reported to be in such a greasy condition that the officials quickly decided to allow non-skid tires to be used, and this concession was quickly taken advantage of. This process delayed the start till well after the appointed hour, and it was close to half past nine when A. Lee Guinness received the word to go.

The red Darracq glided gently down the hill, with clutch out till the main course was reached a hundred yards away; then, with a roar the engine sprang into life and the car was off on its journey of six circuits of the 40-mile course. Almost immediately followed the second Darracq, with K. Lee Guinness at the wheel—the younger brother of the well-known Darracq racing driver. At half-minute intervals the word was given, and silently the cars went away, the scene affording a most pleasant contrast to the usual smoke and noise of a racing event start.

After the 22 Tourist Trophy cars had departed without incident, the nine heavies for the other event were sent away—looking unwieldy monsters with their big wind shields—and sadly the body of officials and pressmen tramped through the mire to the official enclosure, where round the timekeepers' box and the big scoring sheets a considerable body of spectators were gathered together. In but a short time the telephone station on the top of Snacfell mountain reported that the Hillman-Coatalen car was passing, the additional and cheerful announcement being made that the fog on the mountain had risen to such an extent that the cars could hardly be seen and that fast work was rendered impossible for more reasons than one.

Soon Coatalen rushed past the enclosure, having completed his first round in 1 hour 4 minutes, the fastest time of the day. As this car had clearly passed nineteen competitors on the road, its chances were looked upon as excellent, but unfortunately the driver took the sharp turn at Quarter Bridge at an excessive speed and ran into the curb stone, bursting a tire and breaking a rear spring. A quick repair was effected in less than ten minutes and the second round was covered in fast time, but the spring broke again and the popular driver had to retire.

Times Were Slow on Account of Rain.

Meanwhile the other cars were coming through at scattered intervals, but, as was only to be expected on account of the rain and the fog, the times were comparatively slow. Coatalen's time equaled 37 1-2 miles an hour, while the next best time was made by the Beeston Humber, doing 1 hour 13 minutes, or 33 miles per hour.

Hutton's Berliet had the misfortune to break a gear wheel at Pecl, and this unlucky driver was so much delayed that he was hopelessly out of the running. The rain came down unceasingly all the while, and already it was clear that the race was not going to be a success from the spectacular point of view.

The Quarter Bridge corner, which proved the undoing of Coatalen, was also responsible for the only serious accident of the day. The Star car, on the second round, skidded into the wall and seriously hurt the mechanic.

The times for the second round showed that the Arrol-Johnston, driven by Napier, the Trophy's first holder, was at the head, closely followed by the Beeston Humber and the Metallurgique.

The same order was maintained till the fourth circuit, when news of retirements came gradually to headquarters. Both Berliets were out of the race, the extraordinary reason being given that the gear boxes were full of mud. The Darracq of the younger Guinness broke its differential as the result of a bad skid at Ramsey, and the Coventry Humber, the most powerful car in the race, dashed straight into a house at Kirkmichel—hardly half a mile from its garage. Some excitement began to be shown now that the race was nearing its close.

At the end of the fifth round the five first cars were within seven minutes of the leader, and as the wet atmosphere was playing havoc with the fuel consumption, grave doubts were expressed that any car would be able to finish the course. The Metallurgique kept well ahead, and soon the message came through that it had passed Snacfell summit and had but the eight miles of down grade to cover. Two minutes later the Darracq of A. Lee Guinness passed the same station, while the Rover and Beeston Humber were still climbing up from Ramsey several miles behind.

And Then Came the Trophy Winner.

Minutes passed slowly at the finishing line, and no car came in sight. A quarter of an hour, and word was passed along by the signallers on the course that the Darracq was stopped for want of gasoline but two miles from the post. Other cars were

meanwhile finishing their fifth round, and as each came into sight great excitement prevailed when the whistle blew.

Suddenly "No. 22" was announced, and, with a wild swerve Curtiss brought his Rover to a standstill, victorious in his third essay for the Trophy. The winner reported the Metallurgique stopped for gasoline almost alongside the unfortunate Darracq, both having thus been robbed of victory when almost at the end of their journey.

The Beeston Humber came through a few minutes after the Rover, and took second place. Trouble with a wet magneto had delayed the car over 20 minutes in the last two rounds, otherwise the final placing would probably have been reversed. In this connection it is interesting to note that the Humber was one of the few cars which was not equipped with a second ignition system—a provision which would have obviated the fatal delay.

The time for the Rover was given as 8 hours 23 minutes, an average of close on 29 miles per hour. While this performance does not approach the 40-mile-an-hour gait of Rolls last year, nor the Arrol-Johnston 33-mile-an-hour average of the first race, it must be regarded as highly satisfactory in view of the thick fog on the mountain, which at times rendered it impossible for the drivers to see ten yards ahead.

The winning car ran most consistently throughout, and did not vary more than a minute on successive rounds. The car has 4-cylinder engine, 90-inch bore by 110 mm. stroke, with four speeds and live axle.

HOW THE HEAVY TOURIST TROPHY WAS WON.

While the Tourist Trophy of this and previous years has successfully catered for the car of from 16 to 24 horsepower, cars of higher power than this have been left without an event of sufficient competitive importance to stimulate the activities of makers. The institution of the Heavy Touring Car race was the outcome of this demand, and it was intended to include cars of power ranging up to 35 horsepower. The fuel-limitation principle of the Tourist Trophy race was retained, the allowance being fixed at one gallon of standard gasoline for every sixteen miles of the course. Owing, no doubt, to the late announcement of the race, the number of entries did not exceed sixteen, and of these seven were withdrawn.

The distance of the race was originally fixed at seven circuits of the course, or 281 miles, but it was later reduced by two circuits. On the morning of the race the officials suddenly decided to allow an extra one and a half gallons of gasoline in view of the heavy nature of the roads and the big wind, so that the allowance reached one gallon for every fourteen miles. The nine competitors consisted of a Cornilleau-St. Beuve, Berliet, Thorneycroft, Arrol-Johnston, Gladiator, two Ariels and two Beeston Humbers—an almost "all-British" representation.

After the Tourist Trophy cars had been got away, the nine of this heavy class were given the word at half-minute intervals. When but a few miles on his first lap, Arnott had trouble with his Arrol-Johnston and broke a wheel on a dangerous corner. This, strangely enough, was the only trouble experienced in this race, the remaining eight cars running till they finished, or till their fuel gave out. The two Ariels came round first in 1 hour 14 minutes, only seventeen seconds separating the two cars, which ran together very consistently. The big wind resistance can well be gauged by noting that this average speed for 45-horsepower cars—the biggest in the race—only reaches 33 miles an hour. Watson's Berliet came to the front at the close of the second circuit, but this lead was soon lost through tire trouble. Sangster's Ariel was at the head of the procession for the remaining laps and looked a certain winner, but with the worst of misfortune ran out of gasoline but half a mile from the post, twenty minutes ahead of the next car. The only cars to complete the last round were the Beeston Humber, driven by G. P. Mills, and the Gladiator. The Humber's time was 7 hours 11 minutes, or a 28-mile-per-hour average, compared with 7 hours

25 minutes for the Gladiator, and so the Beeston Humber firm carries off the trophy for the first time. It is a matter for comment that the winners in both events are firms who have long been identified with the struggle for supremacy in the British cycle market.

AUTOCYCLE TOURIST TROPHY RACE.

DOUGLAS, May 30.—The first of the annual races intended to be held by the Autocycle Club on the fuel-limitation basis of the Tourist Trophy races, was run off yesterday. Two classes were provided, the single-cylinder section being allowed one gallon of gasoline for every 90 miles, while the multicylinder machines had to cover 75 miles on a like amount. Of the twenty-six entrants in the two classes, but one failed to put in an appearance yesterday morning at the Tynwald Hill. The course covered 15 3-4 miles of hilly ground, so that ten laps gave a total of almost 158 miles to be covered.

At 10 A.M. the machines were started in pairs, the single-cylinder bicycles being rated at 3 to 3 1-2 horsepower, while the engines of the eight machines in the larger section were rated at 5 horsepower.

The favorite was C. R. Collier, on a Matchless machine of 3 1-2 horsepower, and from the start this rider made fast time, averaging 23 1-2 minutes for each lap; close behind came the elder Collier, and till half distance this pair kept at the head of the single-cylinder section. The fifth round ended, each competitor stopped for ten minutes to receive the second half of his gasoline allowance. The leader in the twin-cylinder section had the misfortune to have his machine take fire, and it was disabled. Some half-dozen competitors were retired, mostly through tire troubles. After a fast race, C. R. Collier finished in the good time of 4 hours 8 minutes, an average of 38 1-2 miles an hour over the hilly course. His gasoline consumption equalled 94 1-2 miles per gallon. Two Coventry-built Triumphs finished 15 minutes later, one having only used a gallon for each 115 miles. In the twin section H. Fowler won by 32 minutes in 4 hours 21 minutes, a good performance for an amateur in his first race. Fowler made the fastest lap of the day at an average of 43 miles an hour, which was good going for the course.

20-HORSEPOWER CLEMENT LEAVING PICTURESQUE GLENMOOR.

REMODELED AEROPLANE OF M. VUIA, PARIS, NOW FITTED WITH EIGHT-CYLINDER ANTOINETTE MOTOR DRIVING PROPELLER FORWARD.

AN AMERICAN'S FOREIGN TOURING EXPERIENCES

PARIS, June 9.—Cortlandt Field Bishop, of New York, who has just returned to Paris, had a perilous passage of the Alps in an automobile, by way of the Simplon Pass. He was accompanied by his wife.

"There was nothing on one side but the mountain, and on the other a precipice rising three or four thousand feet, and the slightest slip would have meant death," said he. "The trouble was that the tunnel, built to protect vehicles from avalanches, which naturally would make the more dangerous places safe, was all choked with snow and ice.

"My wife and I, therefore, were forced to go outside the tunnels, where the path was just wide enough to hold the wheels. There were no railings, and the few scattered stones on the edge of the cliff were no great protection. To make matters worse melted snow, which was knee-deep for half a kilometer, made the way perilous. My wife stayed with me in the car all the way.

Advises Americans to Cross Alps Via Simplon.

"The scenery was magnificent. I advise every American touring the Continent to cross the Alps by way of the Simplon Pass. I understand that this week fifty or sixty men are going to clear the tunnels, so that the danger will not be so great. At present the law reads that vehicles crossing the pass must only travel ten kilometers an hour, but this will be changed to fifteen soon, so that the crossing can be made in about three hours. The highest points in the pass are about 2,000 meters. I crossed Simplon June 5, four other automobiles crossing the day before. Last year about 300 made the passage.

"The annoyances of automobiling in Switzerland are very great. In some villages, such as those between Lausanne and Geneva, it is impossible to pass through at any speed without being fined. Annoyances are increasing to such an extent that the French motorists are talking of boycotting Switzerland.

Americans Should Know New German Rules.

"Touring Americans ought to know the new rules in Germany. If they travel with their American papers and arrive at the German border unprepared, it will be necessary to return to New York to have them viséd by the German Consul there. French papers must be viséd in Paris. If you tour Germany for only five days the auto tax is small, but over that there is a big increase. It is also necessary to purchase on entering Germany a large number to hang on the machine, for which is charged from

10f. to 20f., and one has to get a personal license. Added to this is a deposit with the customs officers, and the danger of fines and arrest by gendarmes.

"But in Italy it is just the other way. I have been going to Italy for years, and during my first trip had my head split by a peasant. I now find every one courteous, and don't remember hearing of any one fined. The import tax on benzine has been reduced from 48 centimes a liter to 24, and the roads are continually being improved. There used to be a great lack of road signs, but the Italian Touring Club has put up some 10,000 to 15,000 signs showing the directions. Next to France, Italy is the best place for touring, and there is more to see in Italy for Americans.

France Barred Italy from St. Louis Balloon Race.

"It is now definitely decided that Italy will not be represented in the international balloon race at St. Louis. It is the influence of the French that has brought about this result. This is a big misfortune to America, as the Italian aeronauts are very daring and accomplished. Lahm, who was stricken with typhoid fever and who has been very ill, is rapidly gaining his health, and is coming to Paris this week. Hawley, who is also to enter the cup contest, is expected here to-morrow and will make a number of practice ascents.

"Admiral Sigsbee is all wrong in his estimate of flying machines in time of war. I don't say that at the present time flying machines can absolutely destroy a fleet, although if France gets into war dirigible balloons will play an important part. But I would not now be afraid to sail over Admiral Sigsbee in an airship and dare him to do his worst. Airships are destined absolutely to revolutionize modern warfare, and no navy can be safe from them."

FIRST AUTOMOBILE RACE IN LAND OF CZAR.

Russia has held her first automobile race, from Moscow to St. Petersburg, in which French cars were the exclusive competitors. The course of 645 versts provided very bad going, Duray, who finished first on a Lorraine-Dietrich, being timed in nine hours and twenty minutes. A delay of about half an hour was caused by running over a dog. Champoiseau, who has recently abandoned the motorcycle for racing automobiles, came in second on a C. G. V. machine, two hours later. There were fifteen competitors. The race was held in connection with the first Russian automobile show now being held at St. Petersburg.

SUITABLE MATERIALS FOR AUTOMOBILES*

By ELWOOD HAYNES, OF THE HAYNES AUTOMOBILE COMPANY.

SINCE the first attempt to build automobiles, in the '90s, experimenters have had difficulty in getting materials suitable for the purpose. Steel of high tensile strength was employed, but the results were ever the same. Lower carbon steels were tried, but they lasted only a few weeks or months and then broke short off. Swedish iron did not break, but when the first hard bump was encountered it took a set, and the wobbling rear wheels indicated what had happened. Finally a steel of moderately low carbon was introduced which gave only fair results, and if the car was driven for any length of time over rough roads this also crystallized and broke off.

One of the First Uses of Nickel Steel.

In 1899 a nickel steel axle was introduced into a machine by Messrs. Haynes & Apperson, and the car made successfully a trip from Kokomo, Ind., to New York, a distance of about 1,000 miles, without serious breakage of any kind. This axle was made by the Bethlehem Steel Co., of Bethlehem, Pa., and, so far as is now known, was the first material of this kind ever introduced into an automobile. Nickel steel was used in the axles of cars of this construction for about five years, and not a single case of breakage occurred during that period. Not only was this steel found to be practically free from crystallization, but it possessed a very high elastic limit—about 70,000 or 80,000 pounds—and a tensile strength of over 100,000 pounds, with an elongation of about 15 or 20 per cent.

Soon afterward nickel steel was introduced into the construction of driving chains, and showed great superiority over those formerly made of ordinary steel. When the sliding gears were first used on the automobile for the purpose of changing the gear ratio between the motor and rear axle, trouble again asserted itself in breakage. In vain were gears made of the best form of tool steel; the ends of the teeth would break off when an attempt was made to throw them suddenly into engagement by means of the shifting levers. Trouble of a very serious nature resulted from this, as pieces of the broken teeth would get into the other gears, thus causing them to break, and sometimes the entire train of gears would be almost ground to pieces on account of the breakage first of one gear and then of another.

Nickel Chrome Steel.

Machinery steel, case hardened, was tried, and, while this gave better results, it was by no means satisfactory. The injury and breakage of sliding gears were taken as a matter of course, and almost every person possessing a car equipped with these gears expected sooner or later to make a number of replacements.

It was finally discovered that an alloy consisting of iron, nickel and chromium possessed most remarkable properties. Not only could the steel be hardened by heating to redness and quenching in oil, but it could be given a considerable amount of toughness at the same time by drawing the temper somewhat after the first hardening. If the steel was properly made and afterward properly treated, it was found to be almost impossible to break one of the teeth in a six-pitch gear by means of a heavy hammer. So successful were these gears that they rendered it possible to run an entire season sometimes without the breakage or serious injury of a single tooth. Front axles, steering knuckles, and other important parts requiring high elasticity were made of this steel in certain cars with very good results.

Alloy Tool Steel.

The greatest difficulty encountered by the manufacturer was in the working of the steel, which was found to be extremely diffi-

cult. Fortunately, about the time of its early introduction, a tool steel was discovered which possessed most remarkable properties. This steel consists mainly of an alloy of tungsten, chromium and iron, with but a very small per cent. of carbon. One of the most remarkable properties of this steel is its capability of becoming very hard and tough when quenched from a glowing white heat by dipping into a bath of oil. This method of tempering would ruin ordinary tool steel, but it produces in the tungsten chromium steel a substance which is capable of cutting the hardest forms of nickel steel and nickel chromium steel with comparative ease. While this alloy tool steel is not used in the actual construction of automobiles, it is referred to because its use is essential in the turning and machining of the high-strength alloy steel.

It has been found that the manufacturing and working of nickel chrome steel requires great care, as there seems to be some tendency toward segregation when the steel is in the process of making, which gives rise to hard and soft spots in the finished metal. If an attempt is made to manufacture gears from material of this character, it will be found that some of the teeth are extremely hard while others are just about the right hardness. On the other hand, even if the steel is of uniform composition and texture throughout, it will not stand very great variation of temperature without danger of injury, since it is very sensitive to heat treatment. When properly made and properly treated, however, it is perhaps the most resistant substance yet produced, so far as the resisting of shocks and blows is concerned. It has been found almost impossible to break a tooth from a six-pitch gear made from this material, even with the use of a heavy hammer. This renders it especially suitable for sliding gears which are subjected to the destructive action due to the striking of teeth when forced into mesh while in motion.

The following may be taken as a test of high-quality nickel chrome steel, made by the Krupp Company, of Essen, Germany. It will be noted that much depends upon the treatment of the steel:

Dimensions of Test Bars, 5.91" Long and 0.59" Dia.

	Normal	Slightly Hardened	Greater Deg. of Hardness
Elastic limit, lbs. per sq. in.	86,909	148,072	193,589
Tensile strength, lbs. per sq. in.	111,943	165,326	221,325
Elongation, per cent.	14.5	9.1	7.7
Contraction, per cent.	64.0	55.6	46.2

It will be noted from the above tests also that under the hardening treatment the tensile strength rises rapidly, and the same may be said of the elastic limit, rising as it does from 86,909 pounds to 148,072 pounds when slightly hardened, while the tensile strength rises from 111,943 to 165,326. With a greater degree of hardness the elastic limit reaches 193,589 and the tensile strength 221,325. It will be also noted that the elongation gradually diminishes from 14.5 per cent. in the normal steel to 7.7 per cent. in the more highly hardened specimen. The contraction of area also falls from 64 per cent. in the normal to 46.2 per cent. in the highly hardened steel. The contraction of area does not suffer so much as the elongation. The comparatively small loss in contraction of area is a good sign, since it indicates that the texture of the steel has been well preserved under treatment.

Plain nickel steel containing a very small per cent. of carbon is also a good safe material for automobile work. The following may be taken as an example of a mild low carbon nickel steel:

Elastic limit, 65,146; tensile strength, 81,561; elongation, 23.9 per cent.; contraction of area, 71 per cent.

It will also be observed from this that while the elastic limit is quite low as compared with the nickel chrome steel, it is high as compared with ordinary carbon steel, and that the elongation and contraction of area are very high indeed, indicating a very safe material for almost any construction. This material not only pos-

*Paper read before the American Society of Mechanical Engineers at Indianapolis.

esses these excellent properties, but resists dynamic stress remarkably well—in fact, if the dynamic stresses are not too close to the elastic limit of the steel it will preserve its strength and quality for an indefinite time. The following tests indicate the quality of this material as compared with carbon steel:

Carbon steel, 15,000 vibrations; nickel steel, 34,000,000 vibrations (not broken).

The former shows the carbon steel under combined torsion and vibration, and the latter nickel steel under the same test. It will be observed that whereas the carbon steel withstood only 15,000 vibrations, the nickel steel was not broken under 34,000,000 vibrations.

Vanadium Steel.

Besides the steels already mentioned, there is another which is now attracting considerable attention—namely, that produced by adding a small quantity of vanadium to a nickel steel or chrome steel. Since vanadium has until recently been classed among the very rare elements, it may perhaps be in place to mention a few of its properties. It is prepared from the chlorid VCl_3 , which is reduced by means of a current of hydrogen gas, the chlorid being heated while the reduction is taking place. Simple as this process may seem, it is one of the most difficult known to chemists, and it usually requires three or four days to prepare a fraction of an ounce of the metal by this process. Until quite recently this element and its compounds, owing to their rarity, were very expensive, but we are now assured by the American Vanadium Co. that a sulphid of vanadium has been discovered in an immense quantity in the Andes Mountains of South America, and that they are now prepared to furnish the metal in the form of a ferro alloy, known as ferro-vanadium, in any quantity desired.

This ferro-vanadium contains about 20 per cent. of the latter metal and is readily incorporated with the iron or steel during the melting, either in the open-hearth or crucible process. Mr. J. Kent Smith, who has given the subject of vanadium steel much attention, advocates the open-hearth process as preferable to the crucible process for the making of this steel. This steel possesses most remarkable qualities, notwithstanding the small quantity of vanadium which it contains. One of these is the closeness with which its elastic limit approximates its tensile strength; and, since the former quality is the one in which the greatest dependence is placed, this is a very desirable characteristic. The sharp contraction of area, also a characteristic of this steel, together with the silky fracture it usually presents, is also a strong indication of the splendid quality of this material. Moreover, the fracture is nearly always of this quality, even though the steel has been highly tempered.

The following are the results of some tests made on oil treated bars of the above steel: It is a rather remarkable fact that the vanadium, alone or with carbon, does not give much character to the iron or steel, but when a third element is introduced, such as nickel or chromium, the characteristics of the steel are changed for the better. Whether the vanadium acts as an essential element in the composition of the steel or principally as a purifier is not fully known; it has been found, however, that a certain amount of the vanadium introduced (about 1-4 per cent.) must remain in the steel in order to give it its characteristic properties. Vanadium, however, has a strong affinity for nitrogen as well as for oxygen, and it may be that it acts as a purifier of the steel by combining with minute quantities of nitrogen gas, which might otherwise be occluded in the steel and thus interfere with its compactness and strength.

It will readily be seen that the high elastic limit, strong contraction of area and splendid silky fracture, together with the large number of vibrations which the steel endures under dynamic stress, most strongly recommend this steel as almost ideal for many parts of the motor car. The writer has made some experiments in the forging, and found that it works well under the hammer, though it must not be allowed to become too cold or it will resist pounding to a remarkable degree. It is not readily

injured under the forging hammer, provided due care be taken not to heat it too rapidly. Another valuable property of the steel is the fact that it machines more readily than nickel chrome steel—in fact, more readily than plain nickel steel.

Bronze.

The use of bronzes in the motor car must necessarily be restricted to parts requiring low rigidity, and usually also moderate strength. While it must be admitted that samples of bronzes can be made that approach closely to fairly good grades of steel in tensile strength, elastic limit, and contraction of area, it must also be remembered that the modulus of rigidity of iron and steel is about 28,000,000 pounds, for example, while that of bronze is only about 15,000,000 pounds. This means that a bar of bronze of a given size and form, under given conditions, will deflect nearly twice as much under the same load as a similar bar of iron or steel. In most parts of the car this feature is objectionable, since changes of alignment are likely to occur, unless the parts which are made of this material are especially well designed.

Notwithstanding the above objection, the readiness with which bronze lends itself to the production of castings of various parts, and its freedom from crystallization under dynamic stress, have led to its introduction into many of the minor parts of the motor car, such as small hand levers, carbureters, tubing, crank cases, gear cases, etc. In general, it may be said that it is suitable for the small levers, such as those used for controlling the sparking mechanism, carbureter, etc. Another use for this metal is in bearings, although these require a decidedly different composition from that used for levers, crank cases, and like parts.

The parts requiring strength are usually made from nickel bronze, phosphor bronze, manganese bronze, or aluminum bronze, while the bearing bronzes are composed usually of lead, tin, and copper in various proportions. Under this latter head come also the so-called babbitt metals, which vary greatly in their composition, some of them being composed of lead, copper, tin, and antimony, others of lead, tin, zinc, and antimony, and still others of lead, tin, and antimony. It is not the purpose of the writer to discuss the merits of these various bearing metals, since a number of very good ones can readily be obtained on the market.

Besides the above alloys, pure copper is used to a considerable extent in the construction of radiators, gasoline tanks, etc. It is well adapted for the construction of radiators, since it can easily be soldered; is one of the best conductors of heat, and is readily formed into almost any shape on account of its malleability, ductility, and comparative softness.

Aluminum.

Aluminum is now used very largely in automobile construction, and it is a significant fact that it was first introduced into the automobile in America, though the French used it to some extent quite early for a few minor parts of their machines. Pure aluminum is used only for a few special purposes, and even then to a limited extent—most notably for tubing and radiators. It is quite well adapted for the latter purposes in many respects, but the comparative difficulty experienced in soldering it is somewhat of a drawback. On the other hand, when alloyed with copper or some other metal giving it increased hardness and elasticity, it is well adapted for various purposes, such as seats, gear cases, crank cases, dashes, and various other parts of the car. Its extreme lightness, together with the ease with which it may be machined and the facility with which it may be cast, renders it very useful for many parts of the machine.

An alloy of zinc and aluminum seems to have considerable rigidity and elasticity, as well as quite high tensile strength. It is also cheaper than the aluminum-copper alloy, but experiments made by the writer indicate that this alloy is not safe if subjected to repeated vibrations, since it seems to fatigue quite rapidly and sooner or later breaks off short. For example, a 1-2-inch square bar made of an alloy of aluminum and zinc withstood only about 15,000 vibrations before breaking, while an alloy of copper and

aluminum withstood 1,600,000 vibrations of the same aptitude and frequency without breaking or showing any signs of injury except a very slight set. Aluminum also forms a very light alloy with magnesium, which, however, is too expensive for ordinary use and is somewhat difficult to handle in quantity. A number of other alloys of aluminum have been prepared and to some extent used in automobile construction, the most notable, perhaps, of which is an alloy of tungsten and aluminum, which has been used to a considerable extent abroad, but is not used in American cars so far as the writer is aware.

From the foregoing it may be said that the following substances have proved suitable for the various parts of the automobile:

- a For rear live axles, nickel steel containing from 4 per cent. to 5 per cent. nickel and less than 0.3 per cent. carbon.
- b For front axles, steering knuckles, propeller shafts, etc., vanadium steel.
- c For sliding gears, nickel chrome steel hardened throughout, or mild nickel steel case hardened.
- d For crank shafts, nickel steel or vanadium steel.
- e For frames, low carbon open-hearth steel, mild nickel steel or nickel chrome steel.
- f For nearly all other parts of the car, such as hand levers, tubing, etc., a good open-hearth steel of comparatively low carbon—say 0.4 per cent. or under—is of suitable quality, since there is no advantage gained by using high-class steels for these purposes, for the reason that the rigidity of these parts is of prime importance, and in order to make them sufficiently rigid they must be made much more than sufficiently strong; therefore, since all steels are practically equal in rigidity, one steel is, broadly speaking, as good as another for these parts.

The use of bronze should be restricted largely to minor parts; the reducing gear wheels, small levers, etc., can be made of phosphor bronze, while the bearings should be made of some good composition bronze (an alloy of copper, lead, tin, and zinc answers well for this purpose), but the main bearings for the engine, such as the crankshaft, crank pins, etc., should be made of a special bearing metal, which is very firm and at the same time will not injure the crankshaft in case the lubrication becomes deficient. The crank case of the motor, the gear case, and other similar parts may well be made of aluminum, since it is light, strong, and easily cast into the proper shape. Steel would answer for the above parts if it could be conveniently worked into the proper form.

It will be noticed from the foregoing that the most progressive automobile builders have spared neither pains nor expense in obtaining the very best materials that can be produced, because, in

order to obtain the highest results in automobile construction, it is necessary that material of superior quality shall be used for certain parts of the machine. Perhaps there is no form of construction that taxes the ingenuity of its builders more severely than the building of a good automobile. Take, for example, one of the high-powered touring cars, carrying from five to seven persons and equipped with a motor of 50 horsepower. Now consider that this motor is sometimes geared down to such an extent that its direct torque is multiplied ten or twelve fold on the rear axle; consider further that the driver of the machine is often entirely inexperienced and, to a large extent, ignorant of the strength of the material and the use of power, and it will be realized that the chances for trouble when driving an automobile are certainly very great.

Now add to the stresses and possible abuses from the foregoing the severe jolting and jarring of the rough roads in America, and some idea may be formed of the severe ordeal through which an automobile must pass during a season's run. It has been the general experience of builders that the more ignorant the owner of the machine the greater his complaint. On the other hand, those who are versed in mechanical matters and who know the sizes of parts generally used for heavy stress, often marvel at the strength and endurance of the modern automobile. Factors of safety must be reduced to the minimum in nearly every part of the machine, or excessive weight is sure to occur. Many high-class machines weigh less than 70 pounds to the horsepower, passengers included. Of course, it is not expected that the motor shall be used constantly at anything near its maximum horsepower. One tenth of its brake horsepower is enough for almost any automobile motor when in daily use. High power is simply intended to meet emergencies; but the material throughout the machine must be strong enough to withstand any stress momentarily applied.

The following table gives approximately the strength of various materials used in automobile construction:

Table 2. Strength of Automobile Materials.

	Modulus of Rigidity	Limit Elastic	Strength Tensile
Aluminum alloys	8 to 11 million	10M to 15M	20M to 30M
Phosphor bronze	12 to 14 million	20,000	30,000
Manganese bronze	15 million	35,000	50,000
Aluminum bronze	15 million	50,000	75,000
Wrought iron	23 million	30,000	40,000
Mild open hearth steel....	23 million	40,000	60,000
Tool steel	23 million	80,000	110,000
Nickel steel	23 million	80,000	110,000
Nickel chrome steel	30 million	160,000	130,000
Vanadium steel treated....	30 million	220,000	228,000

All of the above materials stand well under dynamic stress, with the exception of the tool steel, which should not be used for this purpose.

OFFICIAL FIGURES ON AMERICAN AUTO PRODUCTION

UNDER the title of Bulletin 66, Bureau of the Census of the Department of Commerce and Labor, a complete statistical review of the automobile and bicycle industries during the years covering the period from 1900 to 1905 has been prepared. This is the most comprehensive work of the kind ever attempted in connection with the automobile industry, showing, as it does, the number of establishments, capital and labor employed, wages paid, average number of operatives, types of cars built and many other items of information never collated previously.

The work is naturally too exhaustive to attempt to review it here, but it is interesting to note among some of its tables the fact that in 1900 the State of Michigan reported no automobile factories, whereas in 1905 it had twenty-two and turned out not far from 10,000 cars in that year. New York, on the other hand, had 15 in 1900 and only 21 in 1905, its production of cars only increasing from 521 to 1,808 in that time.

Another isolated item that is of considerable significance is to

be found in the statement that "custom work and repairing amounted to but \$73,824 in 1900 and rose to \$851,053 in 1905, the amounts representing repair work almost exclusively."

It is further interesting to note the standing of the various states as automobile producing communities, Michigan now being at the head, with Ohio second, New York third, Connecticut fourth, Massachusetts fifth, Wisconsin sixth, and Indiana seventh, this, of course, representing the relative standing in 1905.

The bulletin also contains a great deal of other detailed information, including that covering allied industries and those not devoted entirely to the manufacture of automobiles, showing in a most striking manner not alone the truly tremendous development to which the automobile industry as a separate entity has attained, but likewise the vast increase in the prosperity of a score or more of other branches of trade for which it has been responsible in this country. The statistics cover every possible phase of both the main and allied industries and are of great value.

RECREATIVE READING OF DIAGRAMS*

By L. BAUDRY DE SAUNIER.

THE mere mention of the word diagram is liable to cause the reader to turn away his head; he looks upon it as a closed science, the utility of which has never been proved. Consequently, he fingers the pages and passes on. If I had to tell my reader, at present so uninterested in diagrams, that these curves would

FIG. 1.—Photographed diagram furnished by a four-cylinder motor. Slight depression during intake, good, but slightly retarded explosion; pressure falls rapidly during first quarter of stroke of piston; slight back pressure from muffler during exhaust stroke.

become to him a real recreation; that there are few pictures that would interest him so much (on condition that he lends me his attention for a quarter of an hour), and that he can read these hieroglyphics without any calculation, he will probably think that I am abusing whatever confidence he has in me.

But to come down to our diagrams and the recreation that they are going to give us. The automobile type of motor most usually employed is, as is generally known, a gas engine, the propulsions of its cylinder or cylinders being due to a series of explosions

FIG. 2.—Sketch of an apparatus for making diagrams. A, hollow tube of piston; B, guide for piston tube; C, cylinder; D, small cylinder; E, spring; F, articulation of parallelogram I, J, K, L; M, arm with pencil attached; G, pencil; s, s, end of piston stroke; b, pressure tube; m, n, curve indicated during compression stroke.

within a closed chamber. It is known also that the power of a motor depends on a number of factors, the principal of which (bore, stroke and number of revolutions being equal) are the quantity of gas and the weight of it absorbed by each cylinder, the point at which the charge is ignited, etc.

But how can the constructor, or even the amateur, know the exact operation of these factors? If a motor possesses less power than its neighbor, apparently identical with it, how can it be known exactly wherein lies the weakness? The constructor could grope; but would he find the defect? Besides, what certitude has he that the motor is giving all the power of which it is capable? And what is there to tell him where to direct his operations?

He must make the motor speak and tell where it is suffering. True, a motor cannot speak; but at any rate it can write, and write with inconceivable accuracy, telling all that is passing within its cylinders and making known all its secrets.

*Translated from *Omnia* by W. F. Bradley

This property of motors is not of recent origin, since Watt toward the end of the eighteenth century, applied to his machine an apparatus by which he could measure the pressure in the cylinder at any point of the stroke. The apparatus which serves as "writing table" for the internal explosion motor has no resemblance with that used for Watt's slow machine. Inventors had serious difficulties in the search for an apparatus which would resist the brutal shocks of an internal-explosion motor, giving frequently twenty, twenty-five, and more explosions a second, without running wild in this terrible dance.

We will not for the moment at any rate, study the apparatuses designed for taking diagrams of the pressure within our motors; but we will see how they work and try to read together some of the notes drawn up by the motors on which they are fitted.

What we want to know is the pressure of the gas, either fresh or spent, at every moment of the stroke of the piston. This will allow us to modify the general arrangement or regulate parts to obtain the maximum power. If, for instance, we note that during the intake the gas entering the cylinder has a distinctly lower than atmospheric pressure we should conclude either that the valve opening was insufficient or that the piping offered an abnormal resistance to the passage of the mixture.

FIG. 3.—Imaginary diagram indicating variations of pressure.

FIG. 4.—Imaginary diagram indicating variations of pressure and depression (below atmospheric).

FIG. 5.—Imaginary diagram indicating variations of pressure in relation to positions of piston in cylinder.

If at the moment of ignition we find a low pressure, we conclude either that the mixture is bad or that the ignition is defective. If, when the exhaust takes place, we find that the pressure in the cylinder does not suddenly drop, we are warned that the valve opens badly, that the muffler is closed, or that the piping is too small.

To obtain a knowledge of the pressure in the cylinder all that is necessary is to unite the interior of the cylinder to a small vertical piston, *D*, on the connecting rod of which has been fixed a pencil, *G* (Fig. 2). The greater the pressure in the cylinder the higher will the piston *D* mount. The spring *E* brings it down when the pressure is lowered. The pencil *G* is made to bear on a sheet of paper having a scale of pressures on the left-hand side,

FIG. 6.—Approximate theoretic diagram. The maximum efficiency, impossible to obtain in practice, is indicated. Compare this with Fig. 7.

FIG. 7.—Actual diagram. I, intake with slight depression; compression and explosion, firing at point m, indicated by 2; there is sluggishness in firing charge; expansion (working stroke) is shown by curve 3, valve opening at n.

each division being equal to one atmosphere. The atmospheric pressure (that at which we live and at which our motors aspire) is at division *I*.

FIG. 8.—Diagram of a weak charge. Much resistance to admission; weak compression; feeble working stroke.

its working. The same for Fig. 4: The pressure mounted rapidly to 13 atmospheres; descended briskly to 9; remained stationary a little time, then fell rapidly to zero.

One element is missing in our observations. We know that the pressure increases and diminishes, but we do not know the positions of the piston corresponding to these variations. To complete our elements, therefore, we must obtain not only the pressure in the cylinder, but at the same time a registration of the position of the piston. Maintaining the vertical scale showing the atmospheric pressure, we establish a horizontal scale (Fig. 5) which will indicate in centimeters—the movement of the piston. Let us suppose that it is a piston with 120 m.m. stroke, or 12 centimeters.

We had seen then by Fig. 5 that the pressure of $5\frac{1}{2}$ atmospheres at point *S* was at the moment when the piston had travelled about 2 centimeters; that at *T* there was a sudden lowering of pressure between the tenth and eleventh centimeters, and that the pressure fell to zero at the end of the stroke.

With these indications it is easy to understand the working of the apparatus illustrated in Fig. 2. The piston *D*, in communication with the interior of the cylinder, moves the pencil in a vertical sense and enregisters pressure; but at the same time the displacement of the piston of the motor carries along this smaller piston and, in consequence, the pencil *G* in a movement from left to right and right to left. There are two pressures at work on the pencil, one moving it vertically and the other horizontally. Influenced by the two forces, curved lines are generally traced.

Supposing that in Fig. 2 the piston is compressing a mixture. We see that the pressure has gradually and normally increased from the point *M*, commencement of the compression, up to point *G*. The piston has still 1 centimeter to travel to reach the end of the stroke. The pencil would then be at *n* and the pressure would reach 4 atmospheres.

Let us now see what curve would be traced for a complete cycle of an internal-explosion motor. Theoretically the operation is as follows: The intake valve opens and aspiration commences (Fig. 6), the piston travelling to the end of its stroke and the cylinder filling. On this stroke the pressure is that of the atmosphere, and we obtain a distinct horizontal line. On the second stroke the piston returns, compresses the gas and in-

If the apparatus should describe the imaginary curve shown on Fig. 3, we should read that the pressure had at first been 2 kilograms; that it had reached $8\frac{1}{2}$ atmospheres at point *P*; had mounted to $11\frac{1}{2}$ at *Q*; that it had slightly exceeded 12 at the maximum; remained at this pressure for a very short time, and rapidly descended to 6 atmospheres at *R*, at which point we interrupted

creases the pressure, consequently the curve mounts more and more upon itself. Let us suppose a maximum pressure of $4\frac{1}{2}$ atmospheres. The curve shows $4\frac{1}{2}$ at the end of the stroke. At this instant—still considered theoretically—the spark is given and the pressure increases instantaneously to 21 or 22 atmospheres; the piston descends rapidly, the gases expand, and the pressure is lowered with rapidity. When the piston reaches the end of its stroke the exhaust valve opens and the spent gases quickly fall to atmospheric pressure. On the fourth stroke the piston ascends and drives out the gases. Supposing that the resistance of the piping and the air striking the gases is nul, the pressure in the cylinder during this stroke remains that of the atmosphere and the line of the fourth stroke is a horizontal one, covering exactly that of the first stroke. The surface outlined by the straight lines and curves represents the quantity of useful work effected by the charge.

FIG. 10.—Diagram of charge with retarded ignition. Firing has not been done during compression stroke (curve 2); the gas, in expanding, has lost some of its heat, and pressure has fallen from *v* to *s*. Charge being fired at *s*, value of working stroke greatly diminished.

Fig. 7 is an actual diagram of a motor having certain defects, but still being very near the average. It will be seen that the surface circumscribed by the upper curve *Q* (from which must be deducted the surface of the small circle *q*, representing negative labor) is distinctly less than that of the theoretical diagram.

In reality the admission valve, the passage of air into the carbureter, etc., offer a certain resistance, producing a slight depression during the intake stroke and causing the line of the first stroke to descend below atmospheric pressure. The line for stroke 2 (compression) mounts progressively toward the maximum, the heat engendered by compression carrying it to 6 or 7 atmospheres. At this moment the gases are ignited.

It is interesting to note the messages that the motor gives us and to read its cry of suffering. Take Fig. 8 for instance. The motor is asking for more food. The admission line descends considerably below atmospheric pressure, a sign that gas is not arriving readily, compression is feeble, and the explosion weak.

Fig. 9 shows ignition too far advanced in a cycle of operations that commenced well. The charge was fired at *s*, when the piston had still 3 centimeters to cover; it ought to have taken place near the point *m*. In Fig. 10 ignition has been enormously retarded. Firing not taking place at the latest point, *v*, the point *s* passes below the compression line, for the non-firing gases at the point

FIG. 9.—Diagram of charge with spark advanced too much. Firing should have been at *s* instead of at *m*.

FIG. 11.—Scheme showing regulation of firing point, charges being fired at *a*, *a'* and *aa'*. At what point of compression stroke should charge be fired to obtain maximum power?

when the piston redescends do not benefit by the compression. To make further experiments, with a view to finding the best firing point he will see by Fig. 11 that if the charge is fired at *a* he departs from the theoretic diagram according to the value *Q*. He has fired too soon. If he fires at *a'* he has departed from the theoretic diagram by the value of the triangle *R*. He has fired too late. By firing at *a''* he will only be removed from the theoretic diagram by the value of the two small triangles *Q'* and *R'*, which together are less than the two preceding ones.

EFFECT OF SIZE ON THE THERMAL EFFICIENCY*

By H. L. CALLENDER, F.R.S.

It is generally admitted, as already explained, that the thermal efficiency—and consequently the mean effective pressure for a given rate of fuel consumption—varies with compression-ratio very nearly in the proportion given by formula (2) for the air-standard. It would be easy to take account of this in the rating formula by substituting for the constant 0.40 in the A. C. formula the value E of the air-standard efficiency corresponding to the actual compression-ratio in the engine. The value 0.40 for the air-standard efficiency corresponds to a compression-ratio of 3.5, which is not uncommon in petrol motors, giving a compression-pressure of 70 pounds above atmospheric. By increasing the compression-ratio to 5.0, the factor E would be increased to 0.48, giving an advantage of 20 per cent. in point of power, of which the A.C. rating takes no account. But this advantage is obtained at the expense of increasing the compression-pressure to 118 pounds, which means that all parts of the engine ought to be made nearly twice as heavy to secure equal safety and smoothness of running, because the maximum pressure and the inequality of torque vary nearly in the same proportion as the compression-pressure.

The obvious objection to including the effect of compression-ratio in a rating formula, is that the volume of the compression-space is not easy to measure directly. It is, however, a comparatively simple matter to observe the effective compression-pressure by inserting a pressure-gauge with a check valve in place of the spark plug. This method has the advantage that the variation of the compression-pressure is much greater than that of the factor E , so that an error of one or two pounds is not a serious matter. The same method would also take account of any super-compression devices which might conceivably be employed to get more power out of a given size of engine. It is certainly most important that some account should be taken of compression ratio in fuel-consumption trials.

Effect of Size on the Mean Pressure.

As already explained, the variation of the thermal and mechanical efficiency with size, is such as to make the mean pressure equivalent to the B.H.P. vary approximately in the proportion given by the factor $(1 - 1/D)$, for similar engines. This factor may also readily be included in the formula, which then becomes, Efficiency Rating B.H.P. = $C D (D - 1)$. (P.C.)

A formula of this kind, in which account is taken of the effect of size, is most useful in comparing the performances of small engines with large, or of multicylinder engines with single-cylinders of equal power. According to the A.C. formula, a four-cylinder engine with 2 inches bore and stroke (like the F.N. motor cycle engine), is rated at 6.4 horsepower, and is equivalent to a single-cylinder of 4-inch bore. According to my experiments the four-cylinder of 2-inch bore could not develop much more than 4 horsepower under ordinary conditions, and would stand no chance against the single-cylinder of 4-inch bore. A four-cylinder of 3-inch bore is equivalent to a single-cylinder of 6-inch bore by the A.C. rating, but according to the P.C. rating the single-cylinder would have an advantage in point of power of 25 per cent. A two-cylinder of equal power on the A.C. rating would have an advantage of about 12 per cent. over the four-cylinder, and a six-cylinder a disadvantage of about 10 per cent. These differences are far from negligible, though they diminish in importance as the size is increased. In practice, these disadvantages of the multicylinder type might no doubt fairly be set against the advantages of reduced weight and more uniform torque, but the necessity of applying some correction remains in comparing different sized engines of the same type.

* Extract from paper read before The Institute of Automobile Engineers, London, continued from THE AUTOMOBILE, June 6, page 934.

An obvious objection to the P.C. type of formula is that the B.H.P. of an engine of 1-inch bore and stroke would be zero. According to the A.C. rating it should be 2-5ths of a horsepower. It would no doubt be possible to get such an engine to run if very delicately made, but the effect of ignition lag would be serious at the normal speed of 6,000 revolutions per minute, and I doubt whether it could be made to give as much as 1-10th horsepower on the brake. Another objection that has been urged against the formula is that the dimensions are not homogeneous. This is incorrect, because the figure 1 in the formula stands for 1 inch, and represents a length. If the bore is measured in millimeters the formula would read, B.H.P. = $D(D - 25.4)/1290$.

The effect of size on the thermal efficiency of small engines, according to the P.C. rating, is nearly as great as that of compression-ratio. The effect of increase of bore from 2 to 4 inches is to increase the thermal efficiency 50 per cent. To produce a similar effect would require an increase of compression-ratio from 3 to 5, and of compression-pressure from 51 to 118 pounds. If it is thought desirable to take account of compression-ratio in consumption trials, the effect of size should also be allowed for. Both are included in a comparatively simple manner in the P.C. formula. For this reason it may be called the Petrol-Consumption (P.C.) Rating, because it gives the relative power for corresponding rates of consumption, *i.e.*, at equal piston-speeds. It takes no account of piston-speed, and corrected for compression the P.C. rating becomes—

$$\text{B.H.P.} = 2.5 E D (D - 1) / 2.$$

Variation of Efficiency with Ratio of Stroke to Bore.

The chief advantage, in point of thermal efficiency, of increasing the length of stroke, especially in engines with high compression, is that the ratio of surface to volume in the combustion chamber may be thereby reduced. The surface of the combustion chamber is the most important in this respect, because the temperature, the temperature-gradient, the pressure, the time of exposure, and the velocity of turbulent motion, are all at a maximum during ignition, and because any loss incurred here affects the whole of the subsequent stroke and produces a maximum effect on the mean pressure. The remainder of the loss under consideration may without serious error be assumed proportional to that which occurs in the combustion chamber. Assuming the combustion chamber to be cylindrical, neglecting pockets, the ratio S/V of surface to volume will be $4/D + 2(r - 1)/L$, where L is the stroke and r the compression-ratio. If the term A/D represents the variable losses proportional to S/V , and if the coefficient A has the value unity for engines for which SD/V is 9, the value of A for any other engine should be $(4 + 2(r - 1) D/L) / 9$ under similar conditions. This reduces to unity in the case where $L = D$, and $r = 3.5$, which we have taken above as the standard case for petrol motors. The value of A will be the same for all engines for which $2(r - 1)D/L = 5$. If we assume that the ratio of stroke to bore is related in this way to the compression-ratio, no alteration in the value of the constant A is required. Complete account of the variation of efficiency is taken by multiplying the formula $D(D - 1)/2$ (which assumes the value 0.40 for the air-standard efficiency) by the factor $2.5 E$, where E is the value of the air-standard efficiency corresponding to the actual compression-ratio of the engine. If the stroke and compression do not satisfy the relation assumed, it is easy to calculate the appropriate value of A . but no account should be taken of it in the rating formula, provided that the compression-ratio is allowed for by the factor E . Any advantage gained in efficiency by improved form of combustion chamber or ratio of stroke to bore, may be fairly credited to the engine, and, *per contra*, any loss due to excessive shortness of stroke, or bad arrangement of valves, is a fair penalty.

If, on the other hand, the value of the compression-ratio is unknown, and it is desired to allow for the probable effect of the ratio of stroke to bore on the efficiency, assuming a standard value of the compression-ratio, the effect may easily be estimated by considering the variation of the coefficient A . If $A = 1$, when $E = 0.40$ and $L = D$, the variation may most conveniently be expressed, in the case of petrol motors, in terms of the excess $X = L - D$ of the stroke over the bore. We thus obtain $A = 1 - 0.5 X/L$, approximately. If this is substituted in place of 1 in the formula $D(D-1)/2$, we obtain,

P.C. rating corrected for stroke, $D(D-1)/2 + XD/4L$.

In the case of petrol motors, X is very seldom so much as a quarter of L , and the added term $XD/4L$ amounts to only 4%, in this extreme case, for a motor of 4 inches bore. Since the value of this correction is somewhat uncertain, if the compression-ratio is supposed unknown, it might fairly be neglected. But in preference to neglecting it entirely, I have generally taken it as $X/6$, being the average value of the correction between $L = D$ and $L = 2D$, and have included it in the correction given below for piston-speed. The probable error will not exceed 1%.

Variation of Piston Speed with Ratio of Bore to Stroke.

It is generally admitted that increase of stroke for a given bore means increase of available piston speed, and that this effect ought to be included in the rating formula. On simple theoretical grounds, I have independently arrived at a formula which appears to satisfy the necessary conditions. Assuming the mass of the piston and connecting rod for a given bore to vary as $(1 + L/nD)$, where n is a constant for a given design, representing roughly the ratio of the weight of the piston to that of the connecting rod when $L = D$, it follows immediately that, for a given maximum intensity of stress in the connecting rod due to the inertia of the reciprocating parts, the piston speed should vary as the square root of the ratio $(n+1)L/(nD+L)$. The possible variation of piston speed according to this formula is comparatively little affected by variations in design. The majority of designs appear to be included between the limits $n=2$ and $n=3$. Between the limits $n=2$ and $n=3$, the variation given by the theoretical formula follows remarkably nearly that given by the cube root of the ratio L/D . But since square roots and cube roots are troublesome to deal with, I have adopted a different type of formula, which is easier to apply, especially in the case of petrol motors where the bore is nearly equal to the stroke. If the excess of stroke over bore, namely $L - D$, be represented by X , being negative when the stroke is less than the bore, the variation of piston speed is approximately

Piston Speed = 1,000 $(1 + X/(2D + L))$ feet per min.

Hill Climb or Speed Test Rating (Power Rating).

In order to correct the rating for the probable variation of piston speed with stroke ratio, it is only necessary to multiply the P.C. rating by the factor $1 + X/(2D + L)$. This correction should not be applied in fuel-consumption trials, because the consumption already takes account of piston speed. But it is required in hill-climbing competitions or speed tests, in comparing the performances of different engines. In the case of petrol motors, where the stroke is nearly equal to the bore, a further simplification may be effected. Since X is small, the factor for piston speed is nearly equal to $1 + X/3D$. Multiplying the P.C. rating $D(D-1)/2$ by this factor, and adding $X/6$ to allow for the effect of excess of stroke over bore on the efficiency, as explained in section 13, we thus obtain the simple formula,

Hill-Climbing Rating = $D(D-1)/2 + XD/6$. (H.C.)

The approximate formula H.C. is not intended to apply for large variations in the stroke ratio. It gives a rating 4.0 B.H.P. for an engine 3×5 , where the complete expression, adding the term $X/6$ for improvement in economy, and allowing the fraction $X/(2D + L)$ for piston speed, would give 3.9 B.H.P. Within these limits the formula is close enough for practical

purposes. But applied to an engine 3×9 it would give 6 B.H.P. where complete expression gives 4.9 B.H.P.

Relation of Power to Weight.

The formula here proposed to represent the effect of size has an important bearing on the question of minimum weight in relation to power. Assuming that power varies as the square of the linear dimensions, it would follow that the ratio of power to weight varies inversely as the linear dimensions, and would increase indefinitely as the size is reduced. If we assume instead that the power varies as $D(D-1)$ for similar engines, the ratio of weight to power reaches a minimum at two inches, and increases far more slowly with bore than in simple proportion to the linear dimensions.

Another important consideration affecting the weight ratio is the compression. If we assume that the maximum pressure is nearly proportional to the compression pressure, and that the strength and weight of the motor and its gear must be proportional to the maximum stress, we may take the compression pressure as a measure of the weight. Taking the air-standard efficiency E as a measure of the mean pressure and the power, we find that the weight/power-ratio is nearly twice as great for a compression-ratio 5 as for a compression-ratio 2, and diminishes with diminution of compression-ratio, reaching a minimum at $r = 1.9$ if $r = 1.40$. The best value of the compression ratio depends on various conditions, but chiefly on the ratio of the load carried to the weight of the motor and its accessory gear. If the load is equal to the weight of the motor, the compression-ratio should be rather less than 3. If the load is double the weight of the motor, the compression should be about 4.5. The above shows that in many cases where weight-saving is a primary consideration it may be desirable to reduce the compression considerably, and that even in automobiles there is no great advantage in increasing the compression-ratio beyond 4.0, provided that lightness and smoothness of running are considered.

Summary of Formulæ.

It will be evident from the previous discussion that no single rating formula can be applied universally. The factors of which account is to be taken, and the data available for comparison, will differ in different cases. Any proposed formula should be capable of modification to suit the requirements of the case to which it is to be applied. I have, therefore, endeavored to show how the formula should be modified to take account of different factors. Assuming that the primary object of a rating formula is to encourage efficiency irrespective of size, the necessary effect of size on the efficiency should always be allowed for in comparing similar engines of different sizes. This is represented by the factor $(1 - 1/D)$, but between the limits 3" and 6" bore the cube root of the diameter may be taken with an appropriate change in the constant. The piston speed may be taken to vary as the factor $1 + X/(2D + L)$, or as the cube root of the ratio L/D . This factor should be employed for power-rating in competitions, but not for estimating power in terms of consumption.

The formulæ are here summarized with reference to the factors of which account is taken in each.

$D =$ bore, $L =$ stroke, $X = L - D$, all measured in inches.

$E =$ Air-standard efficiency = $1 - (1/r)^{\gamma}$, where $r =$ compression ratio.

Efficiency rating. (P.C.)

Bore only, $D(D-1)/2$, or $D^3 \sqrt[3]{D/4.3}$.

Bore and stroke, $D(D-1)/2 + X/6$.

Compression and bore, $2.5E D(D-1)/2$.

Piston speed.

Piston speed = 1,000 $(1 + X/(2D + L))$, = 1,000 $\sqrt[3]{L/D}$.

Power rating. (H.C.)

Bore and piston speed, $(2D + L) (D-1)/6$, or $D^3 \sqrt[3]{L/4.3}$.

Bore, stroke, and speed, $D(L + 2D - 3)/6$,

or $D(D-1)/2 + XD/6$.

The formulæ may be multiplied by $2.5E$ to allow for compression, and by the number of cylinders in multicylinder engines.

How Can This Backfiring Be Cured?

Editor THE AUTOMOBILE:

[779].—Here is a case of back firing into the carbureter, for which, if you can give a reason and remedy, I would be much obliged. I have a Columbia light touring car, with double opposed motor, which gives very good satisfaction, except that at high speeds there is this constant popping and snapping from the carbureter explosions. The motor is very satisfactory except at high speeds.

I have lately had the valves all reground and properly timed. I am also sure that there are no short-circuits in the electrical system. The carbureter is fitted with a dash-pot, with a piston, which when raised by extra suction of fast running admits more air to the mixing chamber. This carbureter is about three inches nearer one cylinder than the other.

The only adjustment possible in this carbureter is that of the dash-pot valve, which can be arranged so that the piston uncovers the auxiliary air valves to a greater or less extent. This I have readjusted in various ways, but it does not correct the difficulty, and I have also seen that the carbureter is clean and all passages free. I would be very much obliged if you would answer this through the columns of "The Automobile."

New York City.

J. C. MOORE.

From your statement in the case, we should judge the trouble you mention arose from some constitutional defect of the carbureter itself, as was the case with not a few of the old types of carbureters. However, that was before the day of the auxiliary air valve and the general adoption of the latter in one form or another seemed to have done away with this more or less common fault of earlier days, as it is rare to come across an instance of this kind now. We have seen numerous explanations of the trouble advanced but have never come across any that we thought satisfactory, apart from those involving exterior causes, such as leaking or improperly timed valves, which you mention do not exist in your case. Assuming that this has been done and that the motor is in good condition otherwise, also that no amount of carbureter adjustment has sufficed to remedy the trouble, we are at a loss to offer any suggestion of definite value, but there are doubtless a number of our readers who have gone through similar experiences in past times and they may be able to shed a little more light on the matter. We should think the makers would also be in a position to do this, as they were doubtless familiar with this difficulty in days gone by.

Neutralizing Exhaust Gases in a Closed Room.

Editor THE AUTOMOBILE:

[780].—I wish to arrange some device which I can keep in my garage which will neutralize or absorb the burnt gas from the motor—so as not to poison the air. Conditions are such that I cannot run the gas out of doors. Can you give me any suggestions as to how to accomplish this?

Denver, Col.

CHAS. A. SCOTT.

We do not know of any device that would accomplish the purpose you require. The process would naturally have to consist of the conversion of the carbonic acid and other gases contained in the exhaust of the motor into oxygen and hydrogen, and there is little doubt but that the cost of the apparatus necessary to do this would greatly exceed that of your entire garage. We should recommend not running the motor in the garage for any length of time. When necessary to run the motor to make adjustments take the car out in the street, if there is no other place available. The only other method would be ventilation, which you state is not possible under the circumstances, though we cannot conceive of a situation that makes clearing out of the noxious gases by natural means out of the question, particularly in a private garage. Not having the situation of your garage before us, it is impossible to make any suggestions of definite value concerning the remedy you are seeking, but regard the installation of any independent device impracticable and would not recommend it.

A Rather Bad Case of Overheating.

Editor THE AUTOMOBILE:

[781].—I am quite a diligent reader of your correspondence columns on motor problems, but I do not remember seeing anything that would solve the little problem which confronts me now. I have a four-cylinder, air-cooled motor, 4x4 bore and stroke, driving a light-weight touring car through planetary transmission. It is, in fact, a 1905 model of the Marlon car, made in Indianapolis, and the whole car has stood up to its work and given excellent service. The problem is now one of proper cooling. No fan is used, the cooling being simply by means of flanges, which are shallow around the cylinder and quite deep about the valve cages. The first year and a half or more the motor did not overheat except under strenuous conditions, but now even a little work on low speed is apt to make it too hot to give maximum efficiency in power.

The exhaust valves were reground last fall, and the car has not been used much since. The commutator seems in good condition, and my storage battery gives ample current; in fact, the ignition part of the engine has been thoroughly gone over very recently. The carbureter, which is of the very simple old style Kingston type, is adjusted to give almost maximum air and minimum fuel without missing, which I have found gives me the greatest efficiency in the long run without overheating. I have tested the compression with a compressometer, which screws into the spark plug holes, and find a low compression with a maximum variation of only two pounds, i.e., the compression runs 25, 26, 27, 26. Doubtless the compression is higher when the engine is warmed up and a film of oil worked into the piston, since this compression was ascertained when the engine was comparatively cool and tested by jerking the starting-handle as rapidly as possible, in order to give as quick a stroke as possible, opening all the petcocks except the one in the cylinder on trial.

After experimenting with oils, I have found that the oil of heavy body and high test is the best for this engine, which uses the splash system. I am convinced that the oil is not at fault, and that the opening and timing of inlet exhaust valves are pretty nearly all right. At first I thought I was running with too rich a mixture, but having changed this, I find the engine still overheats, although not so much. There is a good deal of rust on the outside of the cylinders, but I do not see how this could affect the motor. Do you think that the needle in the spray nozzle of the carbureter has become worn, and would this have any effect with the proper adjustment? When last examined the carbureter seemed to be all right, and has given me less trouble than any other part of the engine.

Knowing what excellent work the engine is capable of, when I toured with it in Illinois and Indiana on hot summer days, and knowing that no part of it has given way or worn out, I am at a loss to account for this overheating. I shall be grateful for any suggestions you may see fit to offer.

Will say further that I frequently prime the cylinders with kerosene to keep them free from carbon, and there does not seem to be any preignition from this cause, although after stopping, if I remove the switch-plug without shutting the throttle, the mixture will explode in the cylinders with an evil odor at the exhaust. Tops of pistons were scraped clean last fall. The car has not been run all told more than 5,500 or 6,500 miles at the most.

St. Louis, Mo.

JOHN GULLY COLE.

It would appear from your statement of the case that the trouble would probably be found to lie in both the carburetion and the ignition. Doubtless too rich a mixture is being used as this tends to overheat an air-cooled motor very badly, owing to the fact that it is very slow-burning and the spent charge issues through the exhaust in a practically incandescent state. Similar conditions in a water-cooled motor would require frequent refilling of the tank to replace the water boiled away. If the carbureter now fitted to the motor cannot be adjusted properly to overcome this objection, it would doubtless be found a good investment to replace it with one of more modern type. The ignition may be contributing to the overheating very materially by delaying the occurrence of the spark to such an extent that the result is the same as that caused by the overrich mixture. That is, the explosion does not take place until the piston has traveled a considerable portion of its downward stroke, thus causing the charge to do most of its burning on its way

out through the exhaust. This naturally causes a great loss of power and is a frequent and unsuspected cause of overheating. Efficient working of an air-cooled motor is dependent to an extent seldom realized by the average autoist, upon the explosion of the charge at exactly the proper moment and in the minimum time, so that the heat developed has as little opportunity as possible to be absorbed by the cylinder walls and valves. In other words, the greatest heat must be developed, its expansive power utilized and the great portion necessarily wasted gotten rid of, all in the shortest possible time. Examine the timer and coil adjustments very closely and see if they are not at fault; their condition may be such that while the position of the spark lever on the steering wheel would give the impression that the car is being run with the spark well advanced, the reverse is the case. An air-cooled motor should always be run with the spark advanced as much as possible, short of the point where knocking occurs. Rust is far from being a good conductor of heat and if the outside of the cylinders is badly rusted, we should certainly recommend that it be removed, although it may not contribute, except in slight measure, to the overheating complained of. The lubrication should be looked after carefully and kerosene injections resorted to more sparingly. Having given good service for such a period, it is certain that the overheating is not due to faulty design, as the trouble would then have appeared earlier. We think a thorough investigation along the lines indicated should provide a remedy and would be pleased to learn of the outcome.

No Benefit from Increasing Spark Beyond Certain Point.

Editor THE AUTOMOBILE:

[782].—I have been much interested in the letters and inquiries which have appeared in your valuable journal from time to time, particularly with reference to matters of ignition. During the four years of my experience as an owner and driver of motor cars, I have been able to trace 75 per cent. of my troubles directly to faulty or defective ignition.

It always occurred to me that the spark usually employed to fire the charge was entirely too small in volume and force to give the engine its greatest efficiency; and recently I had the opportunity of testing the correctness of this theory. Driving with a friend in a car equipped with both storage battery and high tension magneto, the difference in power and speed was remarkable when running on the magneto, and it probably increased the efficiency of the motor no less than 20 per cent.

But many of us having good motors not thus equipped cannot afford to pay out \$150 for a high tension magneto; and in seeking for a way to better my ignition system, I have thought of installing a single coil rated as giving a 2 to 3-inch spark, using a secondary distributor, and supplying the current with a storage battery of 8 volts and 120 ampere hours. In theory, such a coil and system should give eight to ten times the spark given by ordinary coils, and should very nearly approach the force and volume of spark given by the magneto; but whether it will do so in actual practice, I am unable to determine.

An answer to the question presented above will not only oblige the writer, but might prove interesting to the many thousands who, like myself, find their subscription of your journal a source of both pleasure and profit.

Galveston, Tex.

GEO. G. CLOUGH.

We have always been of the opinion that the theory that you hold is erroneous and arc borne out by extensive and numerous investigations, some of them made with painstaking care to ascertain exactly the effect of increasing the spark on the running and the amount of power developed. As both the laboratory and road experiments have led to the same conclusion we think that there can be little doubt but that beyond a certain point, no advantage whatever results from increasing the size or heat of the spark. However, there appears to be considerable misunderstanding on the point where the average autoist is concerned. It follows naturally that if the amount of current is so small that it does not produce sufficient spark to ignite the mixture, increasing it will do so, and if this increase be just enough to fire the charge under the most favorable circumstances, increasing it still further will certainly give it a greater factor of safety and consequently insure more certain firing under changing conditions.

But having increased it to a point where it is capable of firing the mixture under average running conditions, whether these be better or worse, the question becomes, Will it pay to increase it still further? We do not believe so and would not recommend your installing such a powerful coil as you mention. It would be a waste of money and would consume current much faster than you would care to supply it. Your idea that the magneto gives a spark of greater volume and that this accounts for the improved running is not correct. We have had the same experience as that mentioned by you, as far back as 1902, when we found it possible to easily get ten miles more an hour out of a car with magneto ignition than with a battery. We think the greater precision with which the timing is controlled and the fact that the magneto spark becomes stronger as the motor speeds up is accountable for the better service, for, as a matter of fact, it is possible to obtain a spark of much greater volume with a set of accumulators and a coil than with a magneto for obvious reasons. The letter of A. A. Kent, in this issue, is appropos. In it he says: "—nevertheless, after a certain spark heat has been obtained, an increase in the heat will fire the engine no better." For the most exhaustive and complete investigation of the subject that appears to have been made we would refer you to the issue of THE AUTOMOBILE of March 21, 1907, containing an article by W. Watson, D.Sc., F.R.S. We think that probably an overhauling of the ignition system of your car, paying particular attention to the timer as well as the current consumption at the coils would result in improvement, though you naturally cannot expect to equal the results obtainable with a modern magneto.

SUBSTANTIATING MR. JACKSON ON DRY CELLS.

Editor THE AUTOMOBILE:

[783].—Let me first quote from the article of Arthur F. Jackson, in your issue of May 23, as follows:

First—"Dry cells, when properly used, furnish the best ignition. The cheapest, cleanest and safest."

Second—"Many are under the impression that excess of voltage is injurious to coils, but that any ampere rate of current may be used without harm."

The first statement is a very broad one, and while my knowledge of magnetos, etc., is very limited, I want to heartily indorse the statement so far as it refers to wet or storage batteries, and in hope it will help some brother who is searching for good ignition and debating whether or not to spend good money for a storage battery. I want to distinctly state that I gave away my last storage battery, and it was in good condition and of a very well-known make, and I am now relying with perfect comfort and satisfaction on small dry batteries.

These are my reasons: About a year and a half ago I bought a small four-cylinder car of a good make, second-hand. It had in it two storage batteries of four volt 60-ampere hour capacity each. I was given to understand that these cells should be recharged every month or six weeks, whether used or not, so about every three weeks I would take first one and then the other to be charged, and must honestly say I never had any ignition trouble that I could lay to these cells other than the trouble of taking them to be charged, going after them, and paying each time the price of three dry cells, viz., 75 cents.

Being told that I would get more power if I had six volt cells instead of four volt, I decided to find out for myself, arranging my wiring so that with my switch one side I got four volts and on the other side took both batteries in series, getting eight volts. I took a day's run in the country. Using first four then eight volts failed to show any appreciable difference, so I decided not to waste any money changing my batteries for those of six volts.

Last July I sold that car, and when selling it took out one of the wet batteries and replaced it with dry, feeling that it was fair to the purchaser and keeping the one to put in a new car. I purchased a new car of the same make. It had in it 16 small dry cells in series of fours, wired up in two sets of eight, each connected in series-multiple, each set of eight constituting a complete battery connected to one side of the switch. This, as I understood it, would give about six volts from fresh batteries of four volts after some service. I decided at once to give these batteries a fair trial and see what they would do in the way of service, and being told that the double fours to a very great extent avoided the necessity of shifting from one set to the other, I simply ran on the right-hand set until they gave out, and the result was that I ran from about

July 25 until the middle of October, covering over 2,300 miles before the first eight cells gave out. A pretty good record.

Then, wasting no time with ampere meters, I simply threw out these eight cells and put in eight new ones and began to run steadily on the original left-hand set of eight. These carried me until February, when they gave out, partly, I believe, from age, as I did not double my first mileage.

However, I then commenced on my third set, and to-day, with 4,400 miles up, they are still running strong.

I feel very positive of getting from 1,500 to 2,000 miles on every set of eight cells, and in ten months have used up \$4 worth of dry cells, with \$2 worth now in service and partly used up. I have had no battery troubles whatever, and, personally, do not want any storage batteries which would have cost considerably more for recharging, to say nothing of original cost, depreciation, and the trouble of having recharged frequently. Buy fresh cells, be sure your wiring is good in every way, and do not waste time with ampere meters which damage dry cells, hook your cells up in double sets, and you won't have any trouble with the much-abused but very good dry cells.

As I said above, I gave away the storage battery which had been saved from my first car.

Mr. Jackson's second statement hits me very hard, for I certainly was one of the "many." I firmly believed that with low voltage, say not to exceed six, no matter what the amperage, there was no chance for damage to a coil, and I would like very much to read in your valuable paper some further articles on this subject.

New York City. GASOLINE SAL.

RESULTS OF EXTENSIVE IGNITION EXPERIMENTS. Editor THE AUTOMOBILE:

[784.]—I have read with a great deal of interest the articles published regarding the necessity pro and con of a hot spark against a weak spark for igniting gas, and notice in your answer to letter No. 766, from Charles E. Duryea, that you would like to hear other opinions regarding this question. I have a long time refrained from entering my opinion in regard to this, as I did not wish it misconstrued as advertising the ignition system which I have had on the market for the past two years.

However, as this system has so many differences from other systems with which trials have been made and eliminates several points which have made experiments with others somewhat questionable, my experiments may throw some light on the subject.

I use entirely jump-spark produced from non-vibrating coil. The primary circuit made and broken by mechanism driven synchronously with the engine and the secondary current is distributed to the cylinders of the engine. The mechanism by which I made the primary contact will not vary the time of the spark by variation of the contact adjustment. Neither will the strength of the battery have any effect upon the timing of the spark, as is the case with the magnetic vibrator coil where a weak battery is liable to retard the spark or a light adjustment of the vibrator advances the spark, therefore as I am practically positive regarding the timing, I am able to deduct results on the size of the spark.

By thermometer experiments in my laboratory I have shown that a spark at low temperature can be produced by low primary battery voltage of four and a half volts and a spark of many times that temperature can be produced by high battery voltage of fifteen or sixteen and a half volts. I am also able to vary the size of the spark without varying the timing of the motor by an adjustment in the contact maker.

Although my experiments have never been performed with an engine on a test block, tests have been made with a large number of makes of cars on the road. I have invariably found that a low voltage and a light adjustment which produces a weak spark will not fire an engine as powerfully as will a stronger spark; nevertheless, after a certain spark heat has been obtained an increase in the heat will fire the engine no better. This limit varies greatly with different engines and carbureter adjustments.

I draw my conclusions from my own personal experience on over 150 cars of between 30 and 35 different makes, so possibly these results may assist others in their deductions. A. A. KENT.

Philadelphia, Pa.

AN OPINION ON SOLID TIRES FOR SMALL CARS. Editor THE AUTOMOBILE:

[785.]—I have read considerable discussion in your paper on the question of solid tires for automobiles, and they all appear to come either from some doctor, or else from a solid tire maker. I believe that all the doctors almost in their practice use small runabouts of light weight and run on city streets that are paved, where the surface is smooth, and I believe that under such conditions solid tires might give fair service.

As one who can speak from having (country) experience, however, I must say there is another side to it. Two years ago, knowing the faults of the pneumatic tire, and attracted by the literature of a

solid tire manufacturer, I was induced to invest in a set of them and have them applied to my wheels. Now as to the locality where they have been used, I will say that I live where there are quite a number of hills, and some rock on those points; we have no macadam roads and the land is a heavy black soil with very little sand, and, in consequence, our roads are very hard when dry, and have many little bumps or raises even when the ground is worn smooth on the surface.

This makes a road that creates considerable vibration on the springs, even when running at a low speed, say, of 12 miles per hour, and, while the cars that have been using pneumatic tires here have no trouble in making 20 miles per hour, a solid tire will rack a car to pieces at that speed, as it finds and transmits to the springs every little inequality of the road's surface, and while a pneumatic tire will give and roll over a little bump with but slight rise to the axle, a solid tire does not, every claim of the manufacturer to the contrary. Further, solid tires have a side-swaying tendency that gives them the most of the resiliency they possess, and this very side motion makes them very hard to guide and have a tendency to skid off to the side into the ditch whenever you get on a place like the side of a grade.

Now as to my own experience, I have a two-seated touring car with 10-horsepower engine and which weighs, complete, with gasoline, water, and full equipment of tools, exactly 1,800 pounds and which is geared to make only 24 miles per hour at biggest speed. Further, I had it fitted with very resilient full elliptical springs when I had the solid tires applied, and yet in the two years that we have used them I have broken two rear axles and three front steering knuckles. After the first one broke, at no time has the car been run at over 15 miles per hour. I don't dare to. In the two years I have not run it over 1,500 miles, and yet the tires have cut worse than pneumatics doing more work than I do; and I find that whenever a piece gets started to cut out, it either cuts out there very fast, or else the tire breaks square across clear to the bottom. I feel that I have given them a good trial, and I am done with them, and would be glad to sell them for half price.

Cedar Point, Kan.

SOL WILLIAMS.

A SUGGESTION THAT MAY AID No. 767.

Editor THE AUTOMOBILE:

[786.]—In regard to the complaint of No. 767 and your suggestions to same, would say that I am having the same trouble with a four-cylinder car. In my case the trouble is exactly the reverse of your explanation and is due to practically a flooding of the carbureter producing a mixture too rich for explosion. When I succeed in lowering the level of the gasoline in the float chamber so that it is where it should be, just at or a trifle above the opening controlled by the needle valve, the engine starts with a quarter turn. If car is left standing with gasoline turned on, the float chamber gradually fills until the gasoline is almost level with top of float. When this happens, it is impossible to start the engine, hot or cold, until the level of gasoline is reduced to where it should be. When priming and allowing the gasoline to evaporize by waiting a few seconds, before cranking, will start the engine. After it is once started, it runs all right because it uses the gasoline as fast as it comes. Further, if this is the cause of No. 767's trouble, he will find the plugs apt to be sooty and that opening the throttle wide will stop the engine instead of increasing speed. I corrected my trouble of this kind temporarily by putting two or three small corks under the float (loose) the added lifting power of which was sufficient to cause the float to cut off the gasoline flow at the proper level. Then, an added precaution until I get a float which will do its work properly without assistance from foreign bodies in the carbureter, is to cut off the gasoline flow at the petcock before stopping the engine. By so doing, the float chamber does not have the opportunity to fill up slowly when car is standing with engine stopped and I am able to start always by opening petcock and cranking immediately. I shall be glad if this chance to be of any service to you or Mr. 767.

Summit, N. J.

ELIOT GORTON.

BUICK GETS SECOND INSTEAD OF THIRD.

Editor THE AUTOMOBILE:

[787.]—With fairness due to the Buick, I think you should be advised that a protest which I lodged at Wilkes-Barre, Pa., against a special Maxwell racer, on the grounds that it was not a stock car, has been allowed by Referee C. B. Roberts, this giving the Buick second place instead of third, the winning Maxwell making the hill in 3:07, and the special Maxwell racer making the hill in 2:47 having been thrown out.

It is quite possible that you did not get this information, but the facts above are true, the referee having awarded us second prize, which we now have in our possession. We will therefore ask you to place the Buick as second in the \$1,000 event to the winning Maxwell.

H. J. KOEHLER.

Newark, N. J.

MODEL C, THE SIX-PASSENGER, 40-HORSEPOWER TOURING CAR.

CONNECTICUT is coming along as an automobile-building State, having recently received another addition in the shape of the Continental Manufacturing Company, located in New Haven, which is an outgrowth of the University Garage Company, long well-known in the college town. The company was formally incorporated on March 1 of the present year with a capital of \$100,000, and will devote its energies to the construction of the Continental car of foreign design, three models of which are now being placed on the market.

Model C will doubtless be the mainstay of the line, as it is a standard 40-horsepower six-passenger touring car of the generally accepted type. The remaining members of the trio are Model A, a physician's three-seated runabout, equipped with a four-cylinder 35-horsepower motor, and Model B, a semi-racing touring runabout on the same chassis.

The motor design of the touring car is characterized by the use of independent cylinder castings, the dimensions being 4½-inch bore by 5-inch stroke, the valves all being placed on one side and operated from a single camshaft. The latter is also true of the runabout model except that the cylinders are cast in pairs, in other respects the designer having paid particular attention to the simplification of the power plant and chassis in order to facilitate manufacturing, so that on the whole the three models are built along the same general lines, which have been taken from those found so successful in foreign practice. Special gray iron is used in the cylinders and the latter are ground and polished, the connecting rods, valves and gears being made of nickel steel, oil-hardened and ground to finish. Throughout, the details of the design of the motor, as well as that of its essentials of carburetion and ignition, standard and well-settled practice has been adhered to, the makers not attempting to introduce any revolutionary ideas or innovations.

The clutch is of the multiple ring type, consisting of five members, two of which are fitted with cork inserts, while the next step in the transmission of the power consists of a sliding type of gear-set with selective operation, all the pinions being oil-hardened and having their teeth cut with special beveled faces to facilitate the ready engagement of the pinions as well as to make them silent-running. Final drive is by propeller shaft, particularly designed to run in practically a horizontal plane with the car carrying a normal load, attention also having been paid to the matter of ample clearance, 10 inches in the clear being allowed, in which respect foreign standards have been radically departed from in order to adapt the car to American roads. In each model the weight has been centered well between the axles, the motor being placed to the rear of the front axle and the back seats of the tonneau not being extended beyond the rear axle, the latter being an objectionable feature of some American cars that can only be appreciated on trial over a rough road.

equipped with a straight line body of the accepted foreign type; it has ample seating capacity for six passengers with plenty of storage room for baggage under both the front and rear seats. The runabout body is of special design, the body being placed much further back with a recessed type of dash, considerably lower than is the case on the touring car, in order to blend with the lines of the remainder of the car. The seats are also somewhat lower and side doors are provided at the dash on both the runabout types, the physician's car complete, with top, making a most attractive and business-like appearance. A rumble seat is provided, giving a seating capacity of three people, and provision is made for the stowing of a trunk under the chauffeur's seat. Control is by means of the usual small spark and throttle levers mounted on top of the steering column on a stationary sector, while for city driving an accelerator pedal is provided, in addition to a handy muffler cut-out. A somewhat novel innovation in the way of driving control is found in the single pedal acting on both the clutch and the running brake, while a second pedal controls a powerful double brake, in addition to the unusual emergency brake operated by means of a side lever. The factory in which these cars are being turned out has recently been completed, and comprises an L-shaped building running 200 feet east on Olive street and 200 feet south on St. John street, New Haven, each wing being 65 feet wide. It is three stories high and is equipped with modern facilities.

CHASSIS OF THE CONTINENTAL.

While all three models are along the same general lines, each has been specially designed for the purpose in view, the Model A, physician's three-seated roadster, having a 25-horsepower motor and a 100-inch wheelbase. It is shod with 34 by 4 inch tires on all four wheels, and tips the scales at 1,900 pounds. The Model B carries a 35-horsepower motor, has a 112-inch wheelbase and the same tire equipment, but its total weight is only 200 pounds greater, or 2,100 all on. The Model C, which is the standard touring car of the trio, has a 40-horsepower motor and a wheelbase of 120 inches. Its total weight is but 2,500 pounds, and it is also equipped with 34 by 4 inch tires. Particular attention has been paid to the matter of body design in every one of the models, the touring car being

ONE OF WEIGEL'S EIGHT-CYLINDER, 80-HORSEPOWER BRITISH FLYERS BUILT FOR GRAND PRIX RACE.

WEIGEL'S BRITISHERS FOR FRENCH AUTO RACE

LIKE the American champion in the Grand Prix of the Automobile Club of France, the two British candidates for victory have a distinct individuality. Partly owing to the late appearance of the regulations and the still later announcement of the date of the race, and partly because of a desire to show the value of their standard construction, the Weigel Company decided to employ two standard four-cylinder engines on a racing chassis. As will be seen from the illustration of the chassis, the two forty-horsepower motors are placed tandem fashion, with special crankshaft and camshaft, the former being over six feet in length. There are only four throws and five bearings to this unique crankshaft, two pistons being connected to each crank-pin, and two cylinders firing together in the order 1-8, 4-5, 2-7, 3-6. Cylinders, which are cast in pairs, are 130 by 140 bore and stroke. Valves are on opposite sides, operated by cams formed solid with the shaft. Standard forty-horsepower crank-chambers are employed, bolted rigidly to two stiff steel strips forming a foundation for the engine, and preventing strain upon the crankshaft through springing of the frame. Both engine and gear-box are mounted direct to the side frame.

Ignition presents some new features as the result of the grouping of the two engines. It had been intended to construct a special low-tension magneto, with two separate armature windings and two collector brushes. Owing to shortness of the time, however, this had to be abandoned, and two low-tension magnetos of French construction were adopted, driven from spur wheels situated in the center and at the forward end of the inlet valve camshaft. A spur wheel on exhaust camshaft drives the high-tension distributor for the accumulator-fed ignition.

At the present time a single float-feed perpendicular currents carbureter is being employed, placed between the two groups, with induction pipe on the right-hand side passing left and right and entering each pair of cylinders. Experimental work is being carried out, and it is quite possible that in the race the machine will have two distinct carbureters. Tests on fuel consumption have not yet been completed, though the makers declare that it is well within the neighborhood of one gallon per ten miles. It should be noted that the multiplicity of cylinders does not tend toward economical fuel consumption. Even six-cylinder engines are considered to be at a slight disadvantage under the Grand Prix rules, and it is to be feared that the Weigels will be more heavily handicapped than their competitors.

In the transmission there are modifications on the standard type of Weigel machine. A very large fly wheel—unnecessarily large it might be objected—is carried at the rear of the engine. It is somewhat surprising that advantage has not been taken of this special form of construction to place the fly wheel between the two motor groups. The standard multiple disc clutch is fitted, transmitting the power to a special gear-box, giving two-speeds forward and reverse, neither forward speed providing direct drive. Final drive is by cardan shaft and rear live axle of standard touring machine construction.

Naturally, for such a long engine, a special frame has had to be employed. It is of deeply cambered channel section steel, parallel throughout, lined with wood and raised at the rear to clear the back axle. Tubular cross stays are used. The dip of the front axle has been considerably accentuated to get a low-hung body. In general outline the machine has a very pleasing racy appearance, recalling strongly certain Italian racers.

Artillery-type road wheels are shown on the car in our illustrations, but these will be replaced later by wire wheels, at present under construction in the Rudge-Whitworth factory, at Birmingham. Naturally, they will be dismountable. Dunlop tires will be fitted on both the racing machines.

WEIGEL, THE BRITISHER, RECLINING ON HIS ELONGATED RACER.

Smart Effects in Automobile Fashions

By Laura R. Seiple

INCENTIVE towards smart dress for automobiling was never so pronounced; while makers of fashionable toggery were never more encouraged. Society is not content with plain attire as was the case a year ago. Materials employed in many of the handsomest garments are finest imported worsteds, pongees and silk mixtures. Models are as carefully designed as elaborate tailor-mades and headgear is being improved every day. The day of severe motor clothes is past and before many moons we shall hear as much discussion over apparel for the pleasure as the average woman deems necessary for her choicest evening clothes. There was a time not very long ago that little or no interest was given to the fit of the automobile coat; it might be as loose as a cape or as plain as the strictly tailored garment could be made. But now there is a universal cry for fancy effects and the fashionables will not recognize anything short of extravagant materials wrought into the most intricate models, many of which are elaborately trimmed.

Among the novel coats imported for early summer wear is a preponderance of pongee, not the thin, glazy sort, but a heavy, firm texture that insures endurance and is proof against dust. Recently the craze for fitted coats has overtaken society and the woman with a fit figure is sure to include in her automobile outfit one or two of these trig garments. A very charming model is fashioned after the style of a Russian blouse with snug belt and full circular skirt. The collar is rather high and closes with a tab. A panel effect in the front is finished with two rows of fancy buttons set on to give a broad effect, and the full sleeves are finished at the wrist with buttoned-over cuffs to protect the arms. Touches of tobacco brown are introduced in the trimmings appearing on the collar, cuffs and in pipings on the double-breasted front and narrow belt. Such a garment is not only adaptable for automobiling but for driving and traveling.

A rain and dust coat is a valuable possession in summer, whether one owns an automobile or rides in train, carriage or trolley car. One of the fascinating models recently unboxed, is of heavy pongee in its natural color trimmed with brown and tan checked silk, further embellished with pipings of plain brown. This model is loose fitting and differs from other garments cut on similar lines, inasmuch as its elaborate tailoring makes it available for almost any use. The unusual feature about this coat is the novel way in which the panels running from the shoulders to the line below the waist are fashioned. Beginning in the shape of a Gibson shoulder cape they extend down the fronts and curve under the arms, ending in rather good-sized pockets finished with buttons. The high turn-over collar closed with the same fancy bone buttons and the lower parts of the long sleeves echo the treatment both in trimmings and buttons.

Pongee is used in many stylish and inexpensive coats and dresses, but it is sure to look mussy unless in the heavier qualities

that are not made in America. If one does not feel disposed to invest in a fine pongee coat, mohair is next in choice. For actual service there is nothing better, provided the color be excellent in the beginning; if it is not, the result after the first long run in the sun is discouraging; blues and browns suffer most when exposed to strong light, but tans, grays and cream color will give fairly good service if a good quality mohair is used. Some of the most effective garments of this material are in rich plaids. Green and blue combinations are liked by many, while maroons, browns, greens and blues are found in the more elaborate combinations. To return to pongee, it tailors beautifully, keeps its shape well, sheds the dust as no other fabric does and is found in almost any color desired. As a rule, a good wetting will render it unsightly at the seams, which is of course a disadvantage, but if perfectly tailored this disastrous feature can be eliminated by proper staying, sponging and pressing in the beginning.

A good mohair has much to its credit. Some extremely good-looking automobile coats in mohair of excellent quality in soft grays and champagne colors shot with black or white or even green, give splendid service. The majority of these coats are plainly but smartly tailored and without trimming save for stitching and metal or pearl buttons. Now and again one will see the collar and cuffs of plain color corresponding in tone with the accessory color; this is of leather as often as it is of mohair or ribbed silk. There is a strong vogue for checked effects in black and white, brown and white, or with an indistinct thread of bright red or green appearing at distances of several inches apart. A stunning French coat of pongee in that lovely shade of blue known as Copenhagen, is piped with white leather and further embellished with the same material in the form of cut-out figures through which the soft blue appears. Some striking effects are obtained in decided stripes and others less pronounced, but extremely smart in modes having darker stripes and varying widths. The latter combination is, perhaps, the most recent adoption among the new fabrics.

In anticipation of mid-summer motoring, when woolen coats are discarded on short runs, coarse linen of the homespun variety promises to be much to the fore. In appearance and durability the soft, hand-woven linen coat has much to recommend it. Besides being extremely comfortable it is smart when well cut and tailored, and, above all, is washable. Sometimes variation is given to such garments by additional collars and cuffs of velvet, which are detachable. This decoration is seldom if ever found in the ready-made garment, but it is not a difficult matter to have a separate set made to meet the requirement. A practical feature about linen is the dampening and pressing after it has become sadly wrinkled, which treatment renders it like new. If possible, it is always best to have a homespun linen washed and

FITTED COAT OF PONGEE.

COMBINED HOOD, SHIELD, VEIL.

do nicely to slip on over the dainty summer frock with billowy sleeves that would hardly withstand the dragging on and off of a close-fitting wrap, and for short jaunts to a neighbor's lawn party or evening entertainment the kimono coat is ample protection for the occasion. Of these charming little garments there are some stunning effects in tussores, with artistically draped shoulders and loose sleeves ending in points finished with tassels. For this particular use broadcloth in delicate shades is paramount. A charming wrap of this character is in scarlet broadcloth trimmed with gold braid and tassels.

The handsome coats and dresses in supple leather must not be overlooked. Many of these are wonderfully tailored and in lovely colorings, but are practicable only for extended motor runs and for cool weather. A fascinating suit in Russia colored leather is made with gored skirt trimmed with manipulations of leather pipings above the hem which, by the way, is fully five inches from the ground. The trig little coat is semi-fitting with belt to close it as snugly about the waist as one desires. Turned-back cuffs, high collar and flap pockets that button down complete one of the smartest leather costumes brought out this season. A golden-brown crin (horse-hair) hat with extra drop at the back to protect the hair, is cunningly trimmed with rosettes and wings in corresponding color, tipped with green. High boots with Russia leather vamps and suède tops carry out the *tout ensemble*.

As to hats, almost any small shape that will resist the wind and may be comfortable and fetchingly secured to the hair is considered correct. But after all is said and done, there is nothing quite so satisfactory as a big veil arranged over the hat and tied in a coquettish bow at one side, allowing the ends to float in the air. One of the recent arrivals from Paris is an odd little Panama hat, with straight brim and dented crown. The simple trimming consists of a polka dot scarf twisted around the crown and falling over the left side. These ends are so arranged that they may be turned over the top of the hat and tied under the chin when an extra veil is not desired.

Novel effects are always met with enthusiasm, but scarcely has there been such a mad craze for the unusual as the flowered chiffon or crêpe scarfs are creating. Dealers are already beginning to complain of the shortage in the market of these gay head coverings. Some of the handsomest ones are of crinkled crêpe spattered with great bouquets of vivid roses; others are ornate in Persian colorings, while huge polka dots play a leading part among the fancied patterns. Bright red poppies cast among

put through a shrinking process before being made up; this being properly done, there will be no trouble arising from shrinkage after the garment is completed.

One essential point about the motor coat for comfort rather than ostentation is to have collar and cuffs capable of closing snugly. This season designers have introduced a number of picturesque styles devoid of this practical feature, with collarless necks and Japanese sleeves that offer no protection whatever. These

wheat heads and green leaves decorate one of the most daring effects seen in practical use. There are some lovely ones in soft crêpe embroidered with silk in cherry blossoms; others have shattered roses decorating their full length; some in natural colorings, others in self tones.

When it comes to the automobile veil, that answers best all requirements, there is nothing more practical than heavy chiffon shirred on a ring and divided at the back, with long ends crossing and brought forward, where any desired means of securing them may be employed. Of goggles there is little to mention that is new, save for the steel lenses with tiny slits running crosswise. These were first intended for racing purposes, but recently femininity has adopted the unique invention with marked enthusiasm. A photograph of these lenses is shown in the title of this article on the preceding page. At first glance it would seem as though it would be impossible to see through such a small opening as the slits in these steel lenses present, but their close proximity to the eyes makes the radius of vision ample for all necessary purposes.

To briefly summarize, the trend of fashion in automobile apparel, as far as women's garments are concerned, will tax the artistic resources of the art of smart tailoring. So popular has automobiling become that its many devotees demand variety in fashion, and this demand can only be satisfied by designs that are special in character, and which will lend individuality to the wearer.

MOTORCYCLES FOR WOMEN

Some of the foreign papers devoted to outdoor sports sometimes depict women riders of the motorcycle, but on this side of the water the sport has made rather slow progress. A western maker of motorcycles has, however, completed one of these machines for his 15-year-old daughter, and, as she promptly made 65 miles with it over country roads on her first trip, she may be regarded as being to the manner born. The dropping of the frame has naturally brought about some construction problems, which seem to have been well solved. The machine is belt-driven, and in order to avoid the risk of catching the rider's skirts, both wheels have casings.

The maker has also been confronted with a number of other problems in the adaptation of the motorcycle to a woman's use which are more difficult to overcome, at least for the maker himself, for they lie somewhat outside of his province.

They are, in fact, more closely connected with the marketing of the machine, and thus form part of the dealer's duty, and they consist mainly in overcoming the prejudice of the eternal feminine to anything that savors of the mechanical or that requires systematic supervision. It is notorious that a woman never oils a sewing machine nor winds up a watch regularly, so that how to make her realize the pressing necessity of these little attentions in the case of the motorcycle forms a very considerable part of the problem.

MEMORIAL DAY AUTOMOBILE PARADE AT SEATTLE, WASH.

SEATTLE'S AUTO CARNIVAL.

SEATTLE, WASH., June 8.—More than 200 cars participated in the Decoration Day parade, which proved the greatest turn-out of the kind ever held in the Pacific Northwest. The weather conditions were ideal, and as Summer weather has been here for some time there was an abundance of flowers with which to decorate the cars.

One of the large Seattle sight-seeing cars headed the parade with a band. The prizes were awarded as follows:

For the best decorated car, Mrs. Josephine North, Oldsmobile; second prize, G. W. Miller, Winton; third prize, Jonathan Gifford, White.

Mrs. M. Baker and Mrs. J. Froom carried off the honors for electrics driven by women. The car was a Babcock.

Mrs. Garrett Fisher took the prize for gasoline cars driven by women, her machine being a two-cylinder Rambler.

H. Grimshaw took the prize for the most novel decoration effect, his scheme being simply a sedate brown dog wearing a pair of goggles.

Society was well represented at the afternoon race meeting, and there were hundreds of cars on the track.

The interesting event of the day was the five-mile, in which the contestants were Capt. Caine's Thomas, with "Chicken" driving; Pacific Coast Auto Company's Pope-Toledo, with Tommy Pillow at the wheel, and W. O. Williams, of Tacoma, Pope-Toledo, with "Slats" Blanchard driving. The Tacoma car fell out after the second mile, owing to something going wrong with the steering gear. Pillow won the race in 6:05 2-5, with a lead of 300 yards. The winning car later made a mile in 1:12 2-5.

The feature of the program on the second day was the ten-mile race for the *Times* cup. F. G. Plummer, driving a Cadillac, won in 12:11 2-5.

Another thriller was a fifty-mile race for touring cars fully equipped. Plummer also won this, driving a Cadillac, and covering the distance in 1 hour 12 minutes. The L. L. Moore cup was the prize in this race.

HOW AN OHIOAN UTILIZES HIS CAR.

Col. Webb Hayes, of Fremont, O., recently struck upon a rather novel use to which he has been putting his automobile on the famous old homestead of ex-President Hayes. Instead of using a large work horse to mow the lawn, he uses his two-cylinder Reo with a 36-inch lawn mower. His car also furnishes the power for a two-horse scraper and a two-horse iron wheeled wagon to haul rubbish, brush, etc., in. Col. Hayes says that the work is done much more rapidly and easily than with horses. When doing the "lawn stunts" he removes the detachable rear seat in his car, which is a trick requiring but a minute's time, and the car becomes the motive factor of the mowing machine.

WHITMAN TRIES MOUNTAIN CLIMBING.

L. L. Whitman, the famous transcontinentalist, not content with having snowed under all cross-continental records so deeply that it will probably be years before any attempt is made to better his performance, has a hankering for new fields to conquer and has tried his hand at mountain climbing. The accompanying photograph shows the little air-cooled Franklin at the summit of Mt. Wilson, 6,000 feet above sea level; but that Whitman rather tends to the opinion that mountain-climbing, at least of this variety, is somewhat more hazardous than record-breaking on the level is shown by the following, taken from his letter detailing the performance: "The only road consists of a measly little burro trail that had been widened to permit of taking supplies to the top for a hotel and an observatory being built there. As the reconstructed trail was just wide enough to run a small Franklin car on, R. C. Hamlin and myself were fools enough to want to be the first to drive an automobile up it." Regarding the drive itself, he says:

"On the morning of May 28, at daylight, we hit the trail, and after three hours of strenuous work were at the summit—a ten-mile drive, with a good portion of it soft, mealy road, so that it was a case of low speed all the way, and plenty fast enough for me at that, as we crawled along the side of the mountain and looked down 500 to 1,000 feet right off the end of the hub. Some of the turns were so short that we had to 'see-saw' the corners. Half way up we ran into the clouds, and at the summit we were well above the clouds, with the mountain peaks sticking up out of the vapor like so many rocky islands in the sea. We had three miles of driving through the cloud bank, and the moisture gathered on our clothing to such an extent that we were as wet as if we had been caught in a shower. It was a mighty hazardous trip, but we went very slowly, though the view of some of the dizzy heights, with the tall trees looking like so many tooth-picks on end far, far below, made our hair start a little—on the bald places. As soon as the authorities saw what we were up to they closed the trail against further attempts of a similar nature, but not in time to prevent us making the trip successfully. It was a mighty stiff and difficult climb every foot of the way, and we certainly should not recommend it as a pleasure trip."

Great Worth of Road. It is an old, old story—this talk **building to Automobiling.** of good roads and their great worth to a country. France and Britain and other European countries realized the fact centuries ago, with the Romans having been the first to construct highways deserving of the name. Various causes have delayed and interfered with good roads in this country, and, spasmodically, we have accomplished comparatively little except in a few States like New Jersey, Massachusetts, Connecticut, and Rhode Island. Though the one to benefit most, the farmer as a class has been antagonistic rather than favorable to the improvement of the roads, accusing first the cyclers and now the automobilists of working for good highways for their own selfish use, losing sight of the fact that all vehicle owners would have the same opportunity. It may be that the farmer feared that the coming of good roads might—and did, of course—mean increasing cycling's army and consequent annoyance to the owners of horse-drawn vehicles, who seemed to think that the roads belonged to them and there was no call to share with any new conveyance. The same attitude is taken in reference to the automobile except in sections where the farmer himself has become an owner and is comprehending the great boon to him of the motor-driven vehicle.

A man who did conscientious work as commissioner several years ago with the government's Office of Public Road Inquiries was James W. Abbott, who not long since expressed his views in these columns, dwelling particularly upon the results that should follow a national association of all automobile bodies, saying that the time had come for the automobilists to make the roads question their question. But all interests that would be peculiarly benefited by road betterment should have representa-

tion. In the *Pacific Rural Press* of California the Abbott article was reprinted with these comments:

"The policy or statesmanship of Mr. Abbott's suggestion lies in confidence that the automobile is the coming agricultural vehicle and motor. Therefore, though now initiative is needed from other interests, as he suggests, the effort will continually recruit itself from the ranks of agriculturists until what is a most conservative element may become an effective promotive agency."

The various automobile bodies—N. A. A. M., A. L. A. M., A. M. C. M. A., A. A. A., A. C. A., and A. M. L.—are now perfecting an organization, but it certainly seems most advisable to invite the membership of all other associations interested in the building and use of the roads, especially the agricultural element, which should be consulted and be called upon to have a strong voice in the proceedings—or at least have opportunity.

Grade Crossings the Greatest Menace.

Ever since the railroad became a factor in daily life the grade level crossing has taken a constantly increasing toll, and though millions are being spent to eliminate this greatest of all road dangers on steam railways, the trolley has come to complicate the problem so that there has been little actual improvement. Experience has shown that two objects, proceeding toward a common point from different directions, will all too frequently reach it simultaneously, despite their widely varying speeds.

It did not take long to establish this as a fact, and thousands have since been killed in substantiation of it, and still the grade crossing fatality is the greatest of all risks to the autoist as well as the driver of a horse. This being so, it behooves both to exercise the greatest of caution in approaching and crossing such points. The warning to "Stop, Look and Listen" that cost such a large amount of money in Pennsylvania to establish is not a whit too strong. If its admonition were heeded oftener there would be fewer deaths to record. Whether it be danger in this form, a blind turn on a country road, or a long shot at squeezing through a bad place in city traffic, the average autoist is always willing to take chances. It is a specious form of over-confidence born of an intimate knowledge of the great capabilities of the machine, and sooner or later it ends in disaster; most frequently in front of a railroad train. Perfect control and absolute confidence in his machine are two requisites of the good driver, but the autoist who so far abuses them as to take chances at a grade crossing places himself in the same class as the man who rocks the boat and the idiot who "didn't know it was loaded."

South America as a Market for the Automobile.

On few subjects is the average American business man so poorly informed as with regard to the wealth and resources of South America—not future and more or less remote—but actual and present. The man in the street has absorbed the popular notion that, as a whole, the continent that lies to the southeast of us is a measly collection of poverty-stricken republics whose chief, if not only product, is dissension in the shape of frequent-recurring revolutions. Nothing could be further from the reality. It is indeed true of those small sections that form a connecting link between the Mexican border and Colombia, but the area of these countries in the aggregate bears about the same proportion to South America as Rhode Island does to the entire United States.

Brazil, the largest, is considerably greater in area than the United States, and Uruguay, the smallest, represents the equivalent of several good-sized States. Rio de Janeiro and Buenos Ayres are cities of more than a million inhabitants each, and there are numerous others of only slightly lesser importance. That their wealth is proportionate to their size is evident from the number of automobiles already in use. But the majority are of European make and show that the overseas builder has been alive to his opportunities in this direction. It behooves the American maker to do likewise, and the results already gained give some idea of the reward that awaits a live endeavor.

GLIDDEN CARS TO CARRY NAMES ON FLAGS.

Owing to the fact that the touring board of the American Automobile Association has been in receipt of numerous letters asking how cars on the tour are to be distinguished by spectators along the route, it has been found necessary to make a radical departure from the rule prohibiting makers from displaying any form of advertising. This rule remains in force as usual, but as it has come to light that practically every one interested in the tour is likewise interested in some particular make of car and is anxious to know when it passes, the touring board has decided to provide each car with two small pennants, to be placed on each side of the front seats or the dash, bearing the name of the car. By taking this matter in hand neatness and uniformity in the identification marks will be attained and the display of garish and unsightly banners prevented. The pennants will be about three feet long, with the lettering in black or red on a white field, though this detail has not yet been decided upon.

Seven additional entries have been received during the past week, bringing the total thus far up to twenty-seven. Three of the newcomers are touring cars and four are high-powered runabouts, the details of the new entries being as follows:

Car No.	Entrant	Address	Club	Car
19	G. A. Weidely	Indianapolis		24 h.p. Premier
21	T. P. Jones	Pittsburg,	P. A. C.	45 h.p. Pierce Great Arrow
25	A. B. Tucker	New York,	N. Y. M. C.	26 h.p. Dragon
100	A. E. Hughes	Philadelphia		45 h.p. Pierce G. A. Runabout
101	C. A. Coey	Chicago	C. A. C.	60 h.p. Thomas Flyer "
102	H. E. Coffin	Detroit	A. C. of D.	40 h.p. Thomas "Forty" "
103	H. O. Smith	Indianapolis		24 h.p. Premier "

A Newcomer from Michigan for the Tour.

GRAND RAPIDS, MICH., June 10.—Albert E. Meenges, who is building a new car, will enter it in the A. A. A. tour. He hopes to be able to enter two machines, if he can get the second one completed in time.

AUTO DUTIES IN NEW GERMAN TREATY.

WASHINGTON, D. C., June 10.—Under the new commercial agreement entered into with Germany, and which will go into effect on July 1, 1907, remaining in force for one year, the duties to be levied on American motorcycles and automobiles exported to Germany will be as follows: The duty is based solely on the weight, and in the case of motorcycles ranges from 70 marks to 100 marks per 100 kilos, the first figure applying in the case of machines weighing 50 kilos or less, while the last applies to those weighing from 100 to 250 kilos, an intermediate class being taxed 75 marks per 100 kilos. On automobiles the duty is 15 to 40 marks per 100 kilos, and the machines are also divided into three classes: over 1,000 kilos; from 250 to 500 kilos, which pay 25 marks; and from 250 to 500 kilos, paying 40 marks, the mark in each case being figured as the equivalent of 23.8 cents. This forms part of the temporary agreement entered into in order to adjust the commercial relations of the countries until a comprehensive commercial treaty can be agreed upon.

LICENSE SUSPENDED FOR PASSING WRONG SIDE.

BOSTON, June 10.—The first case of the suspension of an operator's license for infraction of the rules of the road occurred when the Highway Commissioners suspended for two weeks the license of John R. McPherson, of Boston, a professional chauffeur. The charge against him was passing a carriage moving in the same direction as the automobile on the right of the road and the right of the vehicle. The Highway Commission has made knowledge of the rules of the road an important requirement in its new chauffeurs' examinations, and it apparently intends to enforce these rules as strictly as the automobile law.

A line of frontier autos is about to be opened between Russia and Germany, both governments consenting, on the Liban to Memel route. The buses carry sixteen passengers, and are of German manufacture.

BLAZING THE WAY FOR THE INVASION.

By GEORGES DUPUY.

MENTON, FRANCE, May 29.—Two thousand miles over the roads of France and Germany, under the blue skies of Italy and around the snow-capped hills of the Tyrol, will soon be the record of the Yankee Stearns. Two hundred kilometers a day is proving a bigger strain on man than on machine, for since coming here the celestial sluice gates have been wide open, and every night finds us soaked in body and spirit. Despite it all, the excellent roads have made motoring not only possible, but have allowed of fast travel.

Out from mountainous Bourg Lastic, where the villagers are still talking of the Pope-Toledo that smashed a farmer's cart before the Gordon Bennett race, to wine-famed Bordeaux, the 248 miles were covered in record time. Down from Bayonne to Biarritz, a distance of 310 kilometers, the Stearns groped along in the inky blackness of night.

In the high mountain villages, where representatives from other lands are not daily visitors, crowds gather around the Stearns night after night and examine it in detail, discussing its self-imposed task and comparing its lines with the more familiar French, German and Italian machines. In the big touring centers the native has a keen appreciation for a good machine, and is showing amazing interest in the forerunner of the Gold Cup party. Those who will join the travelers later will find that the route lies through the most picturesque and interesting spots of Europe that have still the marks of ancient history, not only in the architectural beauties of the place, but in the characteristics of the natives.

To-night, from my attic window overlooking the Allées de Tourney, a good dozen trickling umbrellas are mournfully going up a perpendicular street that leads to a black stone church—but here I stop, at any rate so far as the church is concerned. To-morrow we shall be out on the broad, free highway.

DEALERS CLAIM SELDEN SERVICE INVALID.

Following the action of the upholders of the Selden patent in beginning suit against a number of local dealers handling independent cars, some of the latter have disputed the validity of the service made upon them as agents in law of the makers they represent and made a motion to set aside the service. The motion came up for argument before Justice Hough, sitting in the U. S. Circuit Court on Friday last, the actions being in the name of the Electric Vehicle Company vs. the A. L. Kull Automobile Company, the National Motor Vehicle Company, Homan & Schultz, representing Thomas B. Jeffrey & Co., and others, only the first being reached on the calendar.

Argument in favor of the granting of the motion was made by Frances Rawle, of counsel to the Dragon Automobile Company, Philadelphia, on the ground that the latter and the A. L. Kull Automobile Company were in no way connected other than as buyer and seller, though Mr. Betts, senior counsel to the plaintiffs in the action, stated that it had come to his knowledge that morning that the officers in both companies were the same. His principal contention, however, was that the U. S. Marshal's return could not be traversed on the hearing of a motion—an opinion with which the court was not at all in accord, but consented to direct a reference to hear argument on this technical point of procedure, as well as on the main point of contention.

PARDINGTON ONCE MORE AT THE HELM.

During the absence of Chairman Jefferson DeMont Thompson, of the A. A. A. Racing Board and Vanderbilt Cup Commission, in Europe, the man at the racing helm will be A. R. Pardington, who was the second chairman of the A. A. A. competitive department. While Mr. Pardington is well occupied with Long Island Motor Parkway affairs, it is assured that A. A. A. racing matters will not be neglected. Usually one goes to the busy man to get things done, and that is the case in the present instance.

FOURNIER ON EMPEROR'S RACE.

It is to-day that the elimination trial for the German Emperor's cup will be decided on the Taunus Circuit. On the following day the forty survivors will compete in the final over the same course. So much has been written about the dangerous nature of the Taunus circuit and so much criticism directed against the organization and the recent decision to make the event a two-day race, that it is interesting to hear the views of an impartial contestant.

Henry Fournier, who has just returned to the racing game after several years' absence, and who will drive an Itala in the German event, has spent five days on the circuit and has been round it fourteen times. The road, he declares in *Les Sports*, is less dangerous than the Auvergne circuit, but will probably be more perilous on account of the number of cars and the percentage of less experienced drivers.

"The organization is perfect. It is better than anything we have ever seen in France or elsewhere. An enormous amount of work and the expenditure of a few hundred thousand marks—probably half a million—is the whole secret of its success. Already driving licenses and custom formalities can be arranged at the A. C. F., giving the right to pass free into Germany and avoiding all trouble at the frontier. Count Sierpstorff, the organizer of the course, relates that one of the French drivers, Duray, I think, was detained at the frontier. The newspapers heard of it, and next morning there was a telegram from the Emperor to the Automobile Club: 'Are such stupidities possible in Germany? Advise.' Two days later all was settled.

"You are not asked to admire everything that has been done. You are told to go on the circuit, study it closely, search for defects, and report whatever you find to be unsatisfactory. You are then given permission to run on the course. Your number is painted in enormous letters on the front and rear of your machine, you are given the practice regulations, printed in your own language, with the dates of all the country markets and a note asking you to pay close attention to them. You are further informed that after 8 o'clock in the morning it is forbidden to use a racing machine, and at every curve there are large white stones visible for a long distance, leaving room to pass but preventing all speeding. I have often seen these stones rolled into position. Every morning at the same time throughout the 74 miles of the course the stones are placed.

"The policing of the course for practice work is perfect. I have been round fourteen times on an Itala and have not met either a child or a dog. Already the villages are barricaded, leaving a guarded street on each side in which the children can play. An enormous amount of work has been done at the starting point, grandstands being at the foot of a hill giving a view of six kilometers of road. There are certainly better roads and less dangerous ones, but it is certain that a poor car could not win, especially the second day. From one end to the other the surface is good, indeed of such a nature that one might call it a race track. From the starting point to Homburg the road is 32 feet wide. From here to Oberursel it is a series of streets rather than a road, where it would be impossible to pass a rival if he wished to keep you in the rear. Luckily, however, it is only eight miles long. From Koenigstein to Esch the road is good but terribly hilly. Unfortunately the new road avoiding Limburg and Weilburg is exceptionally narrow and winds continuously. On one side is the river, on the other the mountain; not even a grassy bank on which to pass.

"As for the turns, they start at the beginning and continue throughout. From Dornholzhauser to Oberursel nothing but sharp turns. At Koenigstein a sharp turn to the left followed by a steep grade. At Esch is the beginning of a zigzag. It is so dangerous that, paradoxically, it ceases to be dangerous. There are not even 600 yards in a straight line; perhaps not 200. You just jump from one turn to the other, with as much judgment as possible, without any necessity for braking, but continually

cutting out and opening up. For the motors it is terrible. At one spot you run between two high walls of earth and make such a sharp turn that there is not a yard to spare if the car is not taken round perfectly. A little later is a second turn of the same nature, both of them on a grade which has certainly 15 per cent. Some declare that it is 18 per cent., but I would not swear to this. One thing I am sure of, I have never seen anything like it in my life."

FIVE START ON PEKIN-PARIS RUN.

A cable report from Pekin announces that five automobiles left that city on June 10 for Paris on the 9,300-mile endurance trip, which will break all records for length and originality. Two De Dion Bouton touring cars, piloted by Cormier and Collignon, and a Contal tri-car in charge of Pons, represented France. A Spiker was the single Dutch representative, and Prince Borghese carried Italian colors on an Itala. An enthusiastic send-off was given the small party, a French military band speeding them away with gay selections of music, and foreign ministers and residents wishing the bold travelers all possible good luck. Cormier calculates that they will average less than 100 miles a day.

CHRISTIE OFF TO CAPTURE GRAND PRIX.

After a temporary delay on the dockside, owing to the unwillingness of the steamship company to accept Walter Christie's boxed racing automobile, the American champion for honors in the French Grand Prix, to be run on July 2, was hoisted aboard the *Majestic* last Wednesday. Walter Christie, Louis Strang and the front-drive machine will land at Southampton on June 19. The racer will be immediately uncrated, will cross the Channel for Havre by a steamer leaving the same evening, and will travel by road for the Dieppe circuit without delay. Before sailing Walter Christie declared that the machine had been put into thorough racing trim, and that it would not be used for practice work on the course. A touring machine will be employed to enable the driver to become familiar with the circuit.

DARRACQ RACERS FOR GRAND PRIX RACE.

PARIS, June 1.—For the Grand Prix race, to be run next month, the Darracq firm will use last year's machines, modified to suit the new conditions. It is not yet known whether there will be two or three Darracq racers in the contest, the machine recently sold to M. Heriot having been considerably damaged in the accident which cost Marius Pin his life. Two, however, are certain

CAILLOIS IN NEW DARRACQ GRAND PRIX RACER.

starters—one to be driven by Caillois, who last year had charge of a Thomas in the Vanderbilt race, and the other possibly by Demogeot. There is a rumor that a well-known sportsman, who has bought the third Darracq racer, is endeavoring to obtain the services of Théry, twice victorious in Gordon Bennett races, to return to the racing game as a Darracq driver. Confirmation of this has not yet been obtained.

AILSACRAIG WINS THE BERMUDA RACE

AT the boom of the starting gun at 4:10 P.M., on Saturday, June 8, two trim motor craft passed over an imaginary starting line in the Narrows and headed for distant Bermuda, nearly 800 miles away. Slight mishaps had delayed the start and caused a change of programme. On Friday it was found that the *Ailsa-Craig*, built for Eben Stevens, could not be fitted out

to the rudder head. The bow of the *Idaho* has a moderate rake forward, and the bow sections have a decided flare above the water line. To comply with the regulations a mast has been stepped through the forward part of the cabin top and carries a loose-footed gaff sail; a staysail has also been rigged.

The *Ailsa-Craig*, owned by James Craig, Jr., and Eben Stevens, has been specially constructed to meet the requirements of the Bermuda race. Her designers, A. Cary Smith & Ferris, of New York City, have made her as long as possible to come within the limits of 60 feet, giving her a plumb bow and plumb transom stern, with the rudder hung outboard. The aim has been to produce a boat which could be driven at a high speed in a seaway. She has an unusually high freeboard.

Both Boats Reach Bermuda Safely.

On time allowance *Ailsa-Craig* was victorious in the Bermuda race by 1:16:22. Her actual running time was 64:49:0, compared with 75:2:0 for her rival, *Idaho*. The Craig boat, however, had to accord 8:56:38 time allowance. On the trip from the Lower Bay, New York, fair weather was experienced until Monday night, after which strong westerly winds and rough seas were the order of going. The *Ailsa-Craig* stood up well against the heavy seas, and only stopped once, when the weather had moderated, to shift an igniter. The voyage brought to light but one defect, the insufficient

ventilation of the engine room, which made the work of the engineers particularly arduous. Thomas Fleming Day, who was in charge of the *Ailsa-Craig*, is loud in the praise of his craft, and declares the voyage a success in every way. Five hundred and fifty gallons of gasoline were consumed on the trip. The skipper of the *Idaho* also reports a highly successful trip. From the first the boat fell behind her more powerful rival, and was five miles astern when they lost sight of one another at nightfall. Rough weather was experienced, but the boat proved herself remarkably seaworthy, and no trouble was met with.

AILSACRAIG (CAPTAIN MUELLER), THAT WON THE NEW YORK-BERMUDA RACE.

in time for the noon start from the Scotland Lightship, and it was then determined to send the boats away from the Narrows at a later hour. Meanwhile, at the Motor Boat Club float, on the Hudson, the *Idaho*, her competitor, was being delayed by the absence of one of her crew. A willing substitute was soon found, and when all was ready the little craft swung her anchor aboard and followed the pilot boat *Raymond* down stream in search of her seagoing companion and competitor.

There have been longer motor boat trips than the present one from New York to Bermuda, notably when two American boats, the *Abiel Abbott Low* and *Gregory*, crossed the Atlantic; but in that case the boats were under cruising conditions, whereas the *Idaho* and the *Ailsa-Craig* are under the necessity of going all out. As a test of the seaworthiness and reliability of the motor boat, no competition has ever been held equaling it in strenuousness.

Additional interest is added to the race by the fact that the two boats are of very dissimilar types. The *Idaho*, designed and built by Stearns & McKay, of Marblehead, Mass., for Peter Shields, of Cape May, N. J., is 60 feet over all, 53 feet on the water line, 12 feet 3 inches draft. The motor is the regular four-cylinder 25-horsepower Standard, 6-inch bore by 8-inch stroke. Having been built for use in the shallow waters around Cape May, and only slightly modified to fit for the Bermuda race, her hull is not of heavy construction. Temporary gasoline tanks, bringing the fuel supply to 1,200 gallons, have been fitted, so there is no fear of shortage. The boat is steered from the bridge on the cabin top, and a long tiller for emergency use may be fitted direct

THE IDAHO (CAPTAIN ROBERTS), THAT FINISHED IN SECOND PLACE.

NEWS OF THE CUP RACERS.

Herbert Lytle is to be entrusted with the Pope-Toledo racer, and from the Pope Company comes this information: "We have had any number of applicants to drive our two cars, the racer and the Type XV runabout, in the Vanderbilt race. If we

BERT LYTLE ON HIS NEW POPE-TOLEDO CUP RACER.

made known the names of some of the big race drivers who were after these plums, there would be some new names slated to drive, but we have faith in Lytle. He is the most fearless driver we know and handles a car better. Lytle does not appear to have a nerve in him; he has never been known to lose his self-control, and he has, perhaps, taken more hairbreadth chances than any other driver of an automobile. In fact, Lytle hungers after the dangerous."

From Freeport, Ill., comes information from the Shoemaker Automobile Company that it is constructing a four-cylinder 70-horsepower racing car, weighing only 1,650 pounds, with shaft drive and selective type transmission. The company has great faith in its creation and expects to have it on the roads for trying out in the near future. The same concern intends to enter its 40-horsepower car in many of the important regular stock car contests.

Commenting upon racing, E. R. Thomas says: "I not only favor international stock car contests as well as contests on the order of the Vanderbilt Cup race, but consider them absolutely indispensable for the further mechanical and structural betterment of our automobiles. Endurance runs, tours and road work of all kinds are bound to teach us points, but they cannot compare with speed trials as a source of lessons. The Vanderbilt Cup race shows us the materials to use, the way to design our cars, and what they will stand. International touring car races give us an opportunity to show whether we have taken the proper advantage of those lessons. Not only should the manufacturer encourage such affairs, but he should know that the public has a right to demand them. The more discriminating buyers have come to realize that races such as the Vanderbilt and such as an international stock car race would be are for their benefit as well as that of the man who makes the cars. They have come to see that it is by such means almost entirely that the maker gains the experience that enables him to improve his product, and they know, too, that every race of that kind means money to them, since they can get a better car than before the manufacturer had his racing experience."

When interviewed on the subject of the Vanderbilt Cup race, Henry Rawle, general manager of the Dragon Automobile Company, said that the situation did not worry the Dragon

company, as it had supreme confidence in the A. A. A. Racing Board. Said Mr. Rawle:

"The Racing Board is composed of men of the highest caliber who have the interest of the automobile at heart. They realize that the Vanderbilt is the premier automobile sporting event of the world, and it is my opinion that they will run the race if there is any way in which it can be brought about.

"Regarding the proposed changes in the rules, we have nothing to say. We designed, and are building our cars under the specifications of previous Vanderbilt races, and we feel sure that the cars will give a creditable account of themselves in any event.

"I don't say that, if we had known that a different weight limit was liable to be imposed, we would not, perhaps, have designed a little different car, but there are probably some good reasons for a change, and as it is too late for us to redesign our cars, we are not going to let it worry us."

NEW ROUTES FOR A. C. A. SEALED BONNET TEST.

In making public the list of routes for the four-day Sealed Bonnet contest that is to begin on Wednesday next, the contest committee of the Automobile Club of America figured without its host. Ordinarily the roads selected are in fair shape, but the backward season has caused considerable delay in their annual overhauling, so that road repairers are now at work on them and many are in an almost impassable condition. It is not the intention of the sponsors of the run to make it in any sense a test of endurance, but rather to demonstrate the mechanical perfection of the cars, so that a complete change in the route has been found necessary in order to provide a proper course on which to drive the 600 miles required by the four days of the contest.

As now mapped out, the first day's route will consist of a 150-mile run on Long Island, starting from Long Island City; on the second day the same distance will be covered over the State roads up through White Plains, Mount Kisco, Bedford, and Cross River to Danbury, Conn., and return. For the third day's run the shore road to New Haven and return has been selected, while the fourth day's run will be a repetition of the first.

Since making the former announcement additional entries of a 60-horsepower Thomas Flyer, a 45-horsepower Pierce Arrow and a 30-horsepower Acrocar have been received, bringing the total thus far to 17 cars. Owing to the change in the route, the committee has extended the date for receiving entries to June 15. The entry list at the present writing is as follows:

CLASS A, CARS SELLING AT OVER \$3,000.

American Locomotive Company (Berliet), one touring car.
Lozier Motor Company, two touring cars.
Locomobile Company of America, three touring cars.
Wyckoff, Church & Partridge, Stearns touring car.

CLASS B, CARS SELLING FOR \$1,500 AND LESS THAN \$3,000.

George J Scott Motor Company, one "Glide" touring car.
A. M. Day, one "Elmore" touring car.
Locomobile Company of America, three touring cars.
Atlantic Motor Car Company, one "Stoddard-Dayton" touring car.
Atlantic Motor Car Company, one "Stoddard-Dayton" runabout.
Harry S. Houpt, one "Thomas Flyer" touring car.
Harrolds Motor Car Company, one "Pierce Great Arrow" touring car.
A. M. Robbins, one "Aerocar" touring car.

U. S. M. R. A. ARRANGES A TRACK CIRCUIT.

A twenty-four-hour race for stock cars is to be the feature event of the meet to be held at the Brighton Beach, N. Y., track, August 9 and 10. The United States Motor Racing Association, of which Joseph M. Gaites is the president, will be the promoting body. The same association has applied for the following dates for circular track meets in various parts of the country

June 21-22....	Detroit, Mich.	July 12-13....	Chicago, Ill.
June 28-29....	St. Paul, Minn.	July 19-20....	Indianapolis, Ind.
July 3-4.....	St. Louis, Mo.	July 26-27....	Pittsburg, Pa.
July 6.....	Milwaukee, Wis.	Aug. 2-3.....	Providence, R. I.
July 10.....	Cleveland, O.	Aug. 9-10....	Brighton Beach, N. Y.

ORPHAN'S DAY PREPARATIONS BY THE CLUBS

Quaker City Motor Club to Entertain 1,500 Orphans.

PHILADELPHIA, June 10.—Last Thursday night's meeting of the Quaker City Motor Club was a busy one. Besides the routine business, there was outlined for the coming four weeks a programme which will keep the members quite busy. First in order comes the Orphans' Day run, Wednesday of this week. Then comes the club's first meet of the season, June 28-29. Following this, July 3, will be a reliability run to Wildwood, N. J., with races on beach and boulevard on the 4th. July 14 the club will help entertain visiting Elks.

The Orphans' Day affair is a sure success. Already 125 cars are promised, with additions to the list in each incoming mail. Chairman George H. Smith expects at least 200 cars, which will assure an outing for 1,500 of the parentless little ones. Willow Grove will be the objective point of the outing, and the officials there will throw open all the attractions to their little guests free of charge, besides which there will be a red-letter feed provided by the club.

The feature of the two-day meet which will be pulled off at Point Breeze track will be a 24-hour race, the similar event held a fortnight ago under the auspices of the United States Motor Racing Association having proved such a winner from a sporting viewpoint, if not financially, that there have been insistent demands for a repetition. Besides the headliner, there will be five and ten-mile city championships and two other short-distance events.

The "Over-the-Fourth" outing of the Quakers is the outcome of an invitation from the Wildwood (N. J.) Board of Trade to participate in a race meet on the national holiday, and to give the tourists something to think about on the down trip, on the afternoon of the 3d, the Wildwooders have promoted a reliability run, with special prizes for the clubmen and for outside automobilists as well. Of the eight events on the 4th, which will be run off over the new two-mile-long boulevard, two will be for Quaker members only, to insure a fair amount of plunder for the clubmen.

The Elks reception run, on July 14, will be in the hands of a committee consisting of J. R. Potter, C. E. Shreve and A. T. James, who will outline an itinerary which will give the visitors the best idea of Philadelphia's attractions from an automobile viewpoint.

Harrisburg Hill-Climb for Stock Cars Only.

HARRISBURG, June 10.—Details of the forthcoming hill-climb to be held under the auspices of the Harrisburg Automobile Club on July 4, which will be the first event of the kind fostered by this organization, are now forthcoming. There are to be eight events on the program, and all of them are to be confined to stock cars solely, any special preparations in the way of stripping them of bodies or using special gearing being barred. There will be three prizes for each event, consisting of gold, silver and bronze medals, a silver cup being awarded in addition for the best time of the day. Classes 1 and 2 are for Harrisburg touring cars and runabouts regardless of price, the other classes being graded, Class 3 being for cars costing \$1,000 or under, Class 4 up to \$2,500, Class 5 up to \$4,000, Class 6 up to \$6,000. Class 7 is to be for motorcycles within a radius of 30 miles of Harrisburg, and Class 8 is to be a free-for-all.

Secretary Pierce Resigns from Binghamton Club.

BINGHAMTON, N. Y., June 10.—At a meeting of the Binghamton Automobile Club held last week the resignation of Alderman Norman M. Pierce, as secretary of the club, was accepted, and Mr. Pierce was unanimously elected an honorary member. His resignation is due to the fact that he is shortly to become a resident of Buffalo. S. M. Frechie, the treasurer, has been appointed as secretary, thus combining the two offices. Twenty-eight new members were admitted at the last meeting.

Buffalo Will Celebrate Its Orphans' Day June 26.

BUFFALO, June 10.—At its last regular meeting the board of directors of the Automobile Club of Buffalo has decided to make Wednesday, June 26, Orphans' Day, and has already issued a request to its members to donate the use of their cars for that day for the purpose of providing enjoyment for the many children which it expects to accommodate. Last year's showing was a substantial one, and it is anticipated that the precedent set by the old guard of the club in this direction will prove a strong incentive to the remainder of the club members to make an unprecedented success of the affair.

On Friday last the membership committee of the club held its regular meeting, and the report made shows the club to be in a flourishing condition. On the occasion of its last meeting on May 4, 66 applications for membership were received, but at this meeting no less than 95 were acted upon, bringing the roster up to a total of 806 members, the rate of increase being so rapid and so consistent that it is confidently expected to reach the 1,000 mark by August 1, when an initiation fee will be charged. The club's efforts to facilitate touring in Canada have finally been successful, it now only being necessary to pay a fee of \$5 for the customs and bonding and \$4 for the Ontario license and markers, the secretary taking charge of these details when requested to do so. This result represents the work of a three years' campaign. In connection with its work of regulation, eleven prominent members have just been sworn in as special policemen to put down speeding and reckless driving. To further this end their identity is kept secret.

The Automobile Club of Buffalo has just completed arrangements with the Canadian government for American tourists desiring to take their cars into Canada. Those desiring to cross the border with their cars may do so for the remainder of the present year by paying \$5 for the customs, bonding, etc., and the Ontario vehicle permit and markers cost \$4 additional.

Bridgeport Club to Repeat Hill Climb.

BRIDGEPORT, June 10.—As a result of the great success attendant upon the recent hill-climb up Sport hill on Memorial Day, the Automobile Club of Bridgeport voted to repeat the event on next Labor Day at its regular meeting last week. So much interest was shown that it is thought there will be no difficulty in making the event one of importance to the State as a whole, and efforts will be undertaken to interest the Board of Trade and city officials after the manner adopted at Wilkes-Barre in connection with the Giants' Despair hill-climb there. Reports were received from Ralph Sperry, chairman of the hill-climb committee, and A. L. Riker, referee, showing that the event was a financial success, also that no protests were recorded. It was voted to continue the same committee in office. R. D. Crawford, who drove the Stevens-Duryea Big Six up the hill in 1:32 3-5, was awarded the Yale cup for the amateur driver making the best time in a gasoline car, and has offered the cup as a perpetual challenge trophy to be raced for on Sport hill only.

Active preparations for the celebration of Orphans' Day have been under way for a week past, and culminated yesterday in a trip to Savin Rock by 20 odd cars, carrying between 60 and 100 waifs.

Atlantic City to Hold an Auto Carnival.

ATLANTIC CITY, June 10.—Commencing the week of August 5, Atlantic City is to hold an automobile carnival. On August 5 and 6 there will be a two-day race meet on the beach course at Ventnor under the auspices of the Atlantic City Automobile Club, which has already held two very successful meets on this course, some world's records having been established on the fast straight-away sand stretch of a mile. On Wednesday, August 7, there

will be a grand floral parade along the seven-mile stretch of asphalt of Pacific avenue, with a reviewing stand at the City Park. Silver cups and other prizes are to be awarded, and it is anticipated that there will be a large entry list from Philadelphia and New York. The carnival will end with a three-day automobile exhibit on Young's pier, which is said to be the finest of its kind in existence. The event is being promoted by the Atlantic City Carnival Corporation, composed of the town's leading business men, including Walter E. Edge and Harry Cook, both of whom are well known in New York.

Ohio Valley Autoists Gain a Victory.

WHEELING, W. VA., June 10.—Through its secretary, T. A. Westmyer, the Ohio Valley Automobile Club has been able to score a decisive victory over the toll-gate keepers of eastern Ohio. Up to the rendering of the decision in their favor at St. Clairsville last week, tourists from outside of Ohio have been compelled to pay a toll of five cents a mile, while residents were only taxed half that sum. There has been much dissension between autoists and toll-gate keepers in the past over this matter, sometimes almost coming to blows, but naturally the keeper always got the best of it. The club decided to make a test case and have the thing decided once for all, and to do so had members run through some of the gates, with the result that 2 1-2 cents has been declared to be the legal rate for all alike.

Minneapolis and St. Paul to Hold Joint Race Meet.

MINNEAPOLIS, MINN., July 8.—Arrangements are being completed by the Minneapolis and St. Paul Automobile clubs for the holding of a meet June 28 and 29 on the State Fair Grounds track at Hamline, midway between St. Paul and Minneapolis. H. W. Pickens, manager of the United States Racing Association, signed up contracts whereby that association will furnish drivers for the speed contests. One of the feature events will be a 24-hour endurance contest. The Twin City cup, now held by St. Paul, will be competed for.

The Minneapolis Automobile Club has offered a reward of \$100 for the conviction of any person stealing a machine owned by any member of the club. It has also expressed its willingness to cooperate with the police department in suppressing the scorchers.

Cordial Relations with Public Characterize Geneva Club.

GENEVA, N. Y., June 10.—The Geneva Automobile Club, with a present membership of sixty, is in an exceedingly healthy condition. One of the lines of conduct of the club has always been the enforcement of quiet and reasonable running throughout this section of the country. As a consequence, relations with the public and local authorities are of the best. With a population of 15,000 inhabitants, there has never been an arrest in the city and not a single automobile accident, although Geneva is on the great highway between Buffalo and Albany.

It is hoped that visiting automobilists this summer will drive quietly and reasonably through the city, and thus help continue the good impression that has been created.

Detroit Club's Second Century Run.

DETROIT, June 10.—Last year's "century" held by the Automobile Club of Detroit proved to be such an enjoyable affair for all concerned that it has been decided to repeat it on Saturday next. S. D. Waldon, chairman of the runs and tours committee, is confident of eclipsing last year's event manyfold, as close to 100 entries have already materialized. The day is to be a gala event in more respects than one, as it will be marked by the opening of the new clubhouse, which will be celebrated by a reception and lunch during the afternoon. The combination promises well, and, as Chairman Waldon puts it, both the committees are going to make June 15 a day "to be marked with a white stone."

THE AUTOMOBILE CALENDAR. AMERICAN.

Shows and Meetings.

- Oct. 31-Nov. 7.—New York City, Madison Square Garden, Eighth Annual Automobile Show, Association of Licensed Automobile Manufacturers.
Nov. 30-Dec. 7.—Chicago, Coliseum and First Regt. Armory, Eighth Annual National Automobile Show, and First Annual Commercial Vehicle Show, National Association of Automobile Manufacturers.

Races, Hill-Climbs, etc.

- June 19-22.....—New York City, Sealed Bonnet Contest, under the auspices of the Automobile Club of America.
June 20.....—Albany, N. Y., Annual Tour of the Albany Automobile Club; Route, via New York and Asbury Park, to Atlantic City.
June 26.....—Buffalo, N. Y., Orphans' Day Celebration, Automobile Club of Buffalo.
June 27-28.....—Chicago, Elgin-Aurora Reliability Run, Chicago Motor Club and Chicago Automobile Trade Association.
June 29.....—Reading, Pa., Fair Grounds Track, Race Meet, Reading Automobile Racing Association.
July 4.....—Harrisburg, Pa., Peter's Mountain Hill Climb, Motor Club of Harrisburg.
July 4.....—Houston, Texas, Race Meet, Houston Automobile Club.
July 10.....—Cleveland, O., Start of Fourth Annual Tour of the American Automobile Association, for the Glidden Trophy. Finishes in New York City on or about July 23.
July 13.....—Chicago, Race Meet for the Entertainment of the Glidden Tourists, Chicago Automobile Club.
July 25-28.....—Providence, R. I., Annual Meet of the Federation of American Motorcyclists.
Aug. 1.....—Algonquin, Ill., Hill Climb, Chicago Motor Club and Chicago Automobile Trade Association.
Aug. 9-10.....—New York City, Brighton Beach Track, 24-hour Automobile Race, United States Motor Racing Association.
Sept. 2.....—Bridgeport, Conn., Labor Day Hill Climb, Sport Hill, Bridgeport Automobile Club.
Sept. 5.....—Chicago, Cedar Lake Economy Run, Chicago Motor Club and Chicago Automobile Trade Ass'n.
Sept. 14.....—Albany, N. Y., 95-mile Road Race, under the auspices of the Albany Automobile Club.
Oct. 19.....—St. Louis, Mo., International Aerial Race of the Gordon Bennett Prize. Aero Cub of America.

Motor Boat Races.

- June 15-28.....—Kiel (Germany) Motor Boat Races.
July 20.....—New York to Marblehead, Mass., 270-mile Motor Boat Race. New Rochelle Yacht Club.
Aug. 13-15.....—Chippewa Bay, St. Lawrence River, Gold Challenge Cup Race; American Power Boat Ass'n.
Aug. 22.....—New York to Jamestown (Va.), Annual Cruise American Power Boat Association.
Sept. 2-6.....—Jamestown (Va.) Exposition, Motor Boat Races.

FOREIGN.

Shows.

- Nov. 12-Dec. 1.—Paris, Exposition Decennale de l'Automobile, Grand Palais, Esplanade des Invalides, Automobile Club of France.

Races, Hill-Climbs, etc.

- June 14.....—German Emperor's Cup, Taunus Circuit, Imperial Automobile Club.
June 20-22.....—American Gold Cup, Start from New York for European Tour for American Cars, Georges Dupuy, secretary, 1402 Broadway, New York City.
June 14-29.....—Scottish Reliability Trial, Scottish Auto Club.
July 2.....—Grand Prix, Automobile Club of France.
July 14, 1908....—Paris to London, Aerial Race.
July 15-18.....—Ostend Week, Record Trials, Automobile Club of Belgium.
July 21.....—Ardennes Circuit (Belgium).
July 31.....—Liedekerke Cup for Touring Cars, Ardennes Circuit, Belgium.
July 31-Aug. 8.—Belgium Regularity Contest for Touring Cars, A. C. of Belgium.
Aug. 1-7.....—Criterium of France, 1,750 Miles Touring Competition and 250-mile Race for the Press Cup, A. C. of France.
Aug. 11-29.....—France, Coupe de Auvergne.
Sept. 1-2.....—Italy, Brescia Circuit, Florio Cup. A. C. of Italy.

MICHIGAN STATE AUTOMOBILE ASSOCIATION.

DETROIT, MICH., June 10.—The Michigan State Automobile Association of the A. A. A. has been organized not only with the object of promoting the pleasure of its members, but to increase the number of good roads in the State. Edwin S. George, who is active in all things pertaining to automobiling, is president, and is also the chief officer of the Detroit Automobile Club, and largely responsible for making the Detroit organization as large and influential as it is. Mr. George's activity has been instrumental in bringing about the erection of a fine clubhouse.

EDWIN S. GEORGE.
President.

The vice-president of the organization, Dexter M. Ferry, Jr., is also of Detroit. He is chairman of the legislative committee of the Detroit club, and as such has made it his business to watch out for the interests of automobilists of the State when new measures have come before the legislature.

Dr. D. Emmett Welsh, of Grand Rapids, is secretary of both the State body and the Grand Rapids club. He is also a member of the board of directors of the national organization and is one of the best known professional men in Grand Rapids.

James R. Jackson, of Grand Rapids, the treasurer of the

DEXTER M. FERRY, JR.
Vice-President.

DR. D. E. WELSH.
Secretary.

JAMES R. JACKSON.
Treasurer.

association and chairman of the membership committee, is one of the most enthusiastic autoists anywhere. He is a member of the touring board of the A. A. A. He deserves a large part of the credit for the clubhouse recently erected at Cascade by the Grand Rapids club.

WANTED—A GOOD LONG HILL TO CLIMB.

CLEVELAND, O., June 10.—Saturday's event, which was to have been held at Gates Mill hill, and which has aroused unending interest among local autoists, had to be postponed owing to the opposition of residents in the vicinity to the use of the hill for that purpose. Since then numerous localities have been heard from, but the contest committee of the Cleveland Automobile Club has come to no decisions as yet regarding the place or time of holding the postponed meet. The situation is somewhat complicated by the unusually bad condition of the roads intervening between Cleveland and some of the more promising places for the climb, as well as the fact that the hills themselves are not in the best of condition. No less than sixty-five entries have been received to date for the eight events on the program, and it is confidently anticipated that this number will be largely augmented as soon as something definite regarding the holding of the climb is made public.

TO RUN NEW JERSEY TIE OFF LATER.

Out of the many suggestions made as to the proper awarding of the Shanley and Sinclair prizes for touring cars and runabouts, for which seven cars were tied in the first class and five in the second in the New Jersey Automobile and Motor Club's recent run, has come one that is satisfactory to all concerned, and that is, "Fight it out on the same line"—and "may the best car win," might be added as an afterthought, for each is determined that the honors will be all his when it comes to settling the draw. In the meantime, the names of the cars and the contestants are to be engraved on the cups, though this was opposed at first. J. B. Ryall, whose Matheson finished with a clean score, and F. E. Boland, whose National was in the same class, were both in favor of immediately holding another deciding test, and some of the others held a similar opinion.

The meeting of the winners was held at the same time as the gathering of the Endurance Run Committee, at the clubhouse in Newark, and with the official announcement of the scores by the latter was that of the determination of the former to enter any future contest held, when the car finishing first will be awarded the respective trophy. Before this was settled upon, several other suggestions were made, one of which, that of drawing for the prize, met momentary favor among the runabout winners, but J. W. Mason, who was the lucky man, refused to accept it and stated his desire to have the prize competed for in some future event. J. B. Ryall announced his intention of consulting with the donor of the prize in regard to holding a deciding test later.

SEVEN TIE IN LONG ISLAND TEST.

Apparently the Long Island Automobile Club has undertaken an impossible task. In its two-day endurance test, on Decoration Day, ten machines tied with clean scores in three classes. To get the trophies off his hands, Chairman Charles Jerome Edwards, of the Touring Committee, selected a 186-mile route, from the clubhouse to Riverhead and back, and invited the invincibles to .y conclusions. Although the roads were the roughest and steepest to be found on the island, being along the hilly north shore both outward and returning, it made no difference to the machines, every one arriving at controls on time, consequently having clean scores. Classes A, B and C had to furnish an average of 15, 18 and 20 miles an hour respectively.

When the observers' cards were examined it was found that the Oldsmobile could be eliminated from Class B for having lifted off the commutator cap to remove a little gummed oil, and that in Class C the Pope-Toledo could be marked down for changing a spark plug and the Matheson for losing its dust pan. This left a tie in Class A between a Cadillac and a Maxwell; in Class B between Pope-Hartford and Columbia, and in Class C a three-cornered tie between Packard, Pierce and Winton. Club officials declare it is a hopeless task and will not try again. The competitors in the run were:

CLASS A.

Cadillac, 10-horsepower, Jasper D. Rouke, tied.
Maxwell, 18-horsepower, I. C. Kerkhan, tied.

CLASS B.

Pope-Hartford, 25-horsepower, C. G. Arnold, tied.
Columbia, 24-horsepower, E. H. Barnum, tied.
Oldsmobile, 35-horsepower, R. E. Pardee, penalized.

CLASS C.

Winton, 40-horsepower, C. A. Carlson, tied.
Pierce, 40-horsepower, E. R. Strong, tied.
Packard, 30-horsepower, S. H. Burns, tied.
Matheson, 40-horsepower, R. G. Kelsey, penalized.
Pope-Toledo, 50-horsepower, A. N. Wilcox, penalized.

BAY STATERS WILL RUN TO GLOUCESTER.

BOSTON, June 8.—The annual June outing of the Bay State Automobile Association will be held this year on Saturday, Sunday and Monday, June 15, 16 and 17, at the Colonial Arms, an impossible task. In its two-day endurance test, on Decoration program for the three days.

LAST 1907 LOCOMOBILE AND THE FACTORY STAFF.

On June 8 the Locomobile Company put the finishing touches to the last completed car of this year's output. Designer A. L. Riker is at the wheel, superintendent E. F. Russell beside him. In the tonneau from right to left are Publicity Manager J. A. Kingman, William Shortleeve, A. C. Schultz and Harry Stillman.

OLD ADMINISTRATION RETAINS THE REINS.

BOSTON, June 10.—Because of an effort which was made by some of the members of the Boston Automobile Dealers' Association to oust the present administration, which has been in control almost since the organization of the association, and substitute a new board of directors, the annual meeting last week was the largest and most exciting ever held by the dealers in this city. Every member had been canvassed prior to the meeting and there was a large attendance. The opposition, however, was only successful in electing one new member to the board of directors, the other members being re-elected. The new member is Charles E. Fay, manager of the Ford branch. The members re-elected are J. H. MacAlman, manager of the Electric Vehicle Company branch; F. A. Hinchcliffe, manager of the Winton branch; A. P. Underhill, of the Reed-Underhill Company; J. W. Maguire, of J. W. Maguire & Co.; S. K. Dingle, of the Concord Motor Car Company; George H. Lowe, of the George H. Lowe Company; J. S. Hathaway, of the White branch, and Harry Fosdick, of the Harry Fosdick Company. The officers were re-elected as follows: President, J. H. MacAlman; vice-president, George H. Lowe; treasurer, Harry Fosdick, and secretary, Chester I. Campbell. Secretary Campbell was elected manager of the show to be held in March, 1908.

SPLITDORF MOVES WAY UPTOWN IN N. Y. C.

The Splitdorf Laboratory, for many years located at 17-27 Vandewater street, which is in the heart of downtown New York, has moved almost to the other end of the city—261-265 Walton Avenue, corner 138th Street, in the Borough of the Bronx. Their new plant is a six-story-and-basement structure of the latest fire-proof construction. It has a total floor space of over 50,000 square feet, every foot of which will be utilized by the Splitdorf Laboratory for the production of the specialties with which the name for so many years has been identified. One important feature is the installation of the Edison breakdown system, which can be thrown in at a moment's notice, thus insuring uninterrupted work.

SELDEN AUTOMOBILE CO.'S FIRST CAR READY.

ROCHESTER, N. Y., June 10.—The first car to be constructed by the new Selden Automobile Company will be given a tryout this week. It will be equipped with a motor of sixty horsepower, and will be constructed throughout of the finest material obtainable.

TWO-WHEELERS TO HAVE ELIMINATING RUN.

In order that there shall be no annoying cases of drawn battles to settle at the end of its endurance run, H. J. Wehman, chairman of the committee in charge of the national endurance run of the Federation of American Motorcyclists, has prepared a set of rules that will make the honor worth striving for and the victory well-earned. The event will form a curtain raiser for the annual meet of the organization at Providence, R. I. It will be started from New York City at 4:30 A. M., Tuesday, July 30, and the first day's run will be to Springfield, Mass., 190 miles, via Poughkeepsie, N. Y., Lakeville, Conn., and Lenox, Mass. The remainder of the run, 87 miles, is to be covered in half a day and the route will be via Worcester. Controls for the day and half run will be at Poughkeepsie, Springfield, Worcester and Providence, the schedule being based on a running time of 15 miles an hour, the penalties to be one point for each minute late and two points for each minute early, with a five minute allowance for variation of watches. The competitors will be divided into two classes, A and B, the former consisting of all single-cylinder machines and the latter, two or more cylinders, each starter being given an initial credit of 1,000 points. In order that only one rider shall finish with a clean score, the hill-climbing capacity of the machines is to be tested on Jacob's Ladder in the Berkshires, and its fuel consumption at the track in Providence, by starting the competitors off with a pint of gasoline each. The first ten to finish in the first class and the first five in the second class will be deemed Honor Men and receive gold medals, while each leader will be awarded a diamond medal. The entry fee is \$5, and the entries close July 20, with the chairman, H. J. Wehman, 108 Park Row, New York City.

ANOTHER NON-STOP CADILLAC RECORD.

Over 1,000 miles without the motor stopping one single revolution, and that after the car had already been driven 31,000 miles during the past four years of constant service, is the recent accomplishment of a 1903 Model A single-cylinder Cadillac, formerly owned by Roy McCardell, the well-known humorist.

The start was made from the City Hall in Chicago, on Monday morning, May 27, and his Honor, Fred Busse, the newly elected Mayor of that city, wielded the crank which set the engine going.

The run was a most strenuous and nerve-racking one, for the most part over the streets of Chicago and suburbs. The total run covered 1,221 miles. It might have run several times that distance without stopping, and it was thought for a while to continue the run until the engine should stop, but owing to the fatigue of the drivers, who had been on duty for many hours with but little sleep when each relieved the other, the idea was abandoned when the car had completed the trial as originally planned, and it was retired with well-earned honors.

TO LAY CORNERSTONE OF MAXWELL PLANT.

Saturday, June 22, is to be a gala day for Newcastle, Ind., for it will mark an important step in the town's history. On that day, with much formality, speech-making and general handshaking, the community's advent as a factor in the American automobile industry is to be celebrated. To say that the inhabitants have laid themselves out some in preparation for the auspicious event is to put it mildly indeed. The ceremonies are to be given at 2 P. M., when several lodges and societies will assemble in the Court House Square and march to the site of the factory. The "speechifying" will include addresses by Vice-President Fairbanks, the guest of honor, and by Judges Bundy and Forkner and the Hon. C. S. Hernley. The town will be suitably decorated, and nothing is to be left undone to make the Maxwell coming a thing long to be remembered in local history.

THOMAS DETROIT PLANT NEARLY FINISHED.

DETROIT, June 10.—Some idea of what the new plant of the E. R. Thomas Motor Company at Detroit will look like when completed may be obtained from the accompanying illustration. At the present writing the construction of the plant has already reached an advanced stage, and the company not only expects to complete the building within a very short time, but also to have the entire equipment installed and the machinery turning by

THOMAS DETROIT FACTORY AS IT WILL APPEAR COMPLETED.

September next. The construction is all of reinforced concrete, and the main building is already up to the second floor. The plant will eventually cover the large plot of ground which has a frontage of two city blocks on Detroit's famous Jefferson avenue. This year's output of Thomas Forties has already been completed, so far as the construction departments are concerned, and by the time this appears the testers will have finished with the last of them, as it is expected to ship them on June 15. The total number of touring cars and runabouts turned out reached 503—a figure that will not only be greatly surpassed next season, but earlier deliveries will also be made, due to the largely increased facilities at hand.

SOME TRADE NEWS FROM QUAKERTOWN.

PHILADELPHIA, June 10.—The Harry S. Houpt Company, of New York, opened its handsome new local branch house at 139-141 South Broad Street on last Saturday afternoon. The complete line of Thomas cars was inspected by hundreds of visitors during the day, while Manager Andrew S. Robinson, a former Quaker, who has been connected with the New York house for a number of years, did the honors.

The Carter Motor Car Corporation, of Detroit, has opened an office in the Commonwealth Trust Building, at Twelfth and Chestnut Streets, and is offering treasury stock at \$1 per share to raise funds for the erection of a factory at Berwyn, Md., a suburb of the National Capital.

The Dragon Automobile Company has secured the services of J. C. Middleton as assistant sales manager. He was formerly connected with the Autocar sales department at Ardmore.

PREMIER BRINGS OUT COMBINATION CAR.

Concurrently with their pleasure car business, the Premier Motor Manufacturing Company, Indianapolis, Ind., has been devoting considerable attention to the commercial vehicle end, and their study has been along somewhat out of the ordinary lines. The first concrete results of this extended investigation are illustrated by the accompanying photographs, and, though they are

PREMIER TRUCK IN ITS EVERYDAY BUSINESS ROLE.

not turning these vehicles out for the market as yet, owing to the very heavy demand for regulation pleasure cars, the possibilities of a car such as that shown are evident at a glance. The vehicle shown has proved very successful in service, and has been used steadily for transferring freight to and from the railroad depots, while when equipped with removable seats it accommodates a good number of passengers, as shown by the view of the Premier baseball team, bound for its regular Saturday afternoon game, the other photograph illustrating it with a Premier runabout for shipment. It is designed for a two-ton load, but has an over-

THE TRUCK TRANSFORMED AND ON PLEASURE BENT.

load capacity of almost double that, frequently carrying as much as 7,400 pounds. It is equipped with the standard 24-horsepower Premier motor, sliding change-speed gear, 30-inch wheels, solid tires, and is carried on three-quarter platform springs in the rear and semi-elliptics in front.

AUTOMOBILE IMPORTS SHOW A FALLING OFF.

Advance import returns for the month of May past show a decline in the value of imported cars entered at the port of New York during that period as compared with the same month a year ago. The total valuation in 1906 reached \$466,230.06 and represented 134 cars, while this year but 120 have been brought in with a value of \$409,926.29.

LATEST ADDITION TO THE BERLIET LINE LOOKS POWERFUL.

New 40-horsepower Berliet runabout, the production of the American Locomotive Automobile Company, that is a symphony in cream, offset by delicate green trimmings. It is one of the very fast three seaters that is credited with being able to do better than a mile a minute.

VERY HEALTHY WESTERN AUTO DEMAND.

Robert E. Graham, vice-president of the Acme Motor Car Company, of Reading, Pa., recently returned from the Rocky Mountain country and expressed the following opinions:

"The Pacific coast at this time, so far as my personal observation goes, is about the best market for low and medium-priced cars, that there is in the country. Because of the condition of the streets in San Francisco, rendering them almost impassable for horse-drawn vehicles and because of the long-continued tie-up of the street car lines, the automobile as a means of getting about is almost a necessity.

"A very large trade, too, has grown up with the various mining camps. Distances that were formerly a matter of days for animals to cover, are readily traversable in a comparatively short time with the automobile—a few hours instead of a few days. The most unsatisfactory feature of the Western market, as far as an Eastern factory is concerned, is the great delay in receiving shipments. The railroads claim, however, that they are gradually overcoming this and look for better results in the future. Neither the Pacific Coast nor that portion of the Middle West which I saw appears to have felt the recent stock market depression in any degree.

A ONE-DAY RUN WORTH MENTIONING.

A run that was a record in several respects was made Sunday, when two women drove a 1903 car alone from Springfield to New York in twelve hours total time, and less than ten hours actual

VISITING OLD PLYMOUTH ROCK IN A "FULL JEWEL" CORBIN.

running time. The distance is 157 miles, or more than the average day's run in the Glidden contest and more than will be the task of the cars in the sealed bonnet contest of the Automobile Club of America next week. The women were Mrs. E. Philips, wife of Dr. Calvin Philips, and Mrs. Arthur Jervis, both of New York City. The car was a single-cylinder Knox, of ten-horsepower, that has been in continuous service since 1903. The car is that of Mrs. Philips, and she was the driver. Mrs. Philips is as proficient in the care of the car, and even in its repairs, as a professional chauffeur, and takes pride in going out alone with it. The start from Springfield was made at 10 A. M. The roads were very bad, especially from Springfield to Hartford, but the women brought the car through without mishap, stopping for meals more than two hours and arriving at the Rutland, Fifty-seventh street and Broadway, at 10 P. M.

THINGS DOING AMONG THE GARAGES.

Rochester, N. Y.—Fire Marshal Walter has been asked permission by A. Vernon Hart to construct a garage in Cambridge street, near Park avenue. The building is to be of brick, two stories high, and will cost \$12,000.

Toledo, O.—J. J. Maher has just purchased the garage and rubber business of the Cooney Company, at 120-122 Twenty-second street, and will continue the business without change under the name of the Maher Garage Company.

Chicago.—Wolf & Ring have just opened a new garage on Leland avenue, west of Evanston avenue, this city, that is up-to-date in every respect. A specialty will be made of towing and touring livery, sundries, repairs and overhauling.

Lowell, Mass.—Under the title of the City Hall Garage, a new auto station has been established on Moody street. It is most completely equipped in every respect, and has ample accommodation for 100 cars. Fred Walsh is the manager.

Marysville, O.—Dr. O. H. Thorpe has just opened a small garage here which he has placed in charge of Byron Ellis. Accommodation is provided for twenty odd cars, and supplies will be handled. In addition cars will be kept for renting and machines will be sold on order, no stock being carried.

Muskogee, I. T.—The Southwestern Automobile & Vehicle Company has been organized here with a capital of \$25,000. W. E. Gordon is president; J. S. Weeks, vice-president; W. C. Frankline, secretary; A. G. Harmon, treasurer, and W. R. Waton, second vice-president. A regular garage business will be done.

Providence, R. I.—The C. D. Snow Company is now running at full blast in its new quarters at Broad street and Potter avenue, which they took possession of some time ago. The facilities that have since been installed make this one of the most ambitious establishments in the New England district. The company confines its attention to the Stevens-Duryea line.

Nappanee, Ind.—Keller & Jeffries are building a new garage to accommodate about twenty-five cars. It measures 30 by 60 feet and is two stories high, and will be equipped with an up-to-date repair shop, as well as other facilities for taking care of machines. Nappanee is on the route of the Glidden Tour, and the proprietors expect to have their establishment in running order by the time the A. A. A. tourists strike the town.

City of Mexico.—Under the title of El Garage Anglo-Mexicano, what is probably the most extensive auto establishment south of the Mexican border, has just been inaugurated in the Calle Providencia, number 7. Owing to its distance from other facilities it is most completely equipped in every respect, having a large machine shop and carrying a very large stock of spares. As its name indicates, it makes a specialty of British cars, handling the Argyle, Leader and Humber, beside carrying a very complete assortment of accessories and clothing. The company is a corporation with a capital of \$100,000, all paid in.

BRIEF ITEMS OF NEWS AND TRADE MISCELLANY

Application for membership in the New York Automobile Trade Association has been made by the Waltham Manufacturing Company, makers of the Waltham-Orient, and the Corbin Motor Vehicle Corporation.

Additional evidence that the motor vehicle for commercial purposes is surely and rapidly displacing the horse-drawn vehicle is furnished by Arnold, Constable & Co., New York City, who have just received four Maxwell delivery cars and put them into commission. It is very probable that this big house will dispense with its horse service entirely.

Returning from a three weeks' visit to the Pacific Coast cities, Charles B. Shanks, general sales manager of the Winton Company, declares that San Francisco looks infinitely better than when he was there just after the fire. Automobile interest in the West is growing with the country, the demand for highest quality cars being decidedly on the increase.

The annual excursion and picnic of the Winton employees, at Cedar Point, June 17, will also be participated in by the employees of the American Ball-Bearing Company, and the Baker Motor Vehicle Company. The three big plants of these companies will close to give the excursion right of way. A ball game between the Winton and the Ball-Bearing teams will be a feature.

Work is progressing favorably on the new steel and concrete building to be used for the factory of the Pennsylvania Auto-Motor Company, at Bryn Mawr, Pa. The plant will be so arranged that the raw stock can be taken into the factory from a railroad siding at one end, pass through the building, and return to the same siding. Arrangements are being made for 500 regular machines next year, deliveries to begin early in September.

In a recent report made by the Chamber of Commerce, Syracuse, N. Y., it was shown that the automobile was the greatest of their one hundred and thirty different industries, the H. H. Franklin Manufacturing Company having increased their business during the past three years to a point where they now employ seventeen hundred men, which is more than the total number employed by the fifty-two clothing manufacturers, the forty-eight foundries and machine shops, and nearly twice as many as employed by the three typewriter factories.

Toledo, Ohio, comes into notice just at this time, when speed laws are so widely discussed, by cutting down the speed limit to ten miles per hour and organizing a motor-cycle police corps, who are keeping close tab on automobile speeders, and particularly the Pope-Toledo testers. A few years ago the Pope people established a course on the outskirts of the city, but were compelled to retire to the "tall timbers" on account of speed laws. The company has now selected a stretch outside the city limits, which includes sand, mud, and all kinds of hills, and think they now have a course which cannot be beaten for testing.

Michelin & Cie, of Clermont-Ferrand, France, have just notified their Ameri-

can agents, E. Lamberjack & Co., of New York City, of another remarkable performance by Michelin tires. Starting from Paris at 2 p. m., May 6, Sorel, in a 60-horsepower De Dietrich stock car, covered the 930 miles of rough roads between Paris and Madrid in the wonderful time of 28 hours 14 minutes. This record is attested by officials, and not only lowers the best previous time for automobiles, but is faster than the fastest express train running between these two cities. The run was made in a rain-storm, at an average rate of thirty-four miles per hour. Michelin tires were used during the entire trip.

RECENT BUSINESS CHANGES.

The Rambler agency in Chicago, which for a long time has been located in Wabash Avenue, near Congress street, has removed to 1462-1464 Michigan Avenue, in the heart of the local auto selling district.

F. E. Goodwin has purchased the property of the Motor Components Manufacturing Company, of Des Moines, Iowa, from the receiver for \$2,555.61. The company recently went into the hands of a receiver upon petition of Grover Hubbell and B. S. Walker. W. H. Kitto, formerly secretary, now has suits pending for \$100,000 damages against these parties.

NEW AGENCIES ESTABLISHED.

The Corbin Motor Vehicle Corporation, of New York, has issued engraved cards of invitation for an inspection of its new offices and salesrooms, at 1892 Broadway.

The Dragon Automobile Company, of Philadelphia, is about to open a city showroom and office in that city to handle retail trade. The new headquarters will be located in the latest addition to automobile row, opposite the Union League.

William G. Isbell, formerly associated with Guy R. Pierce in the Chicago agency for Baker electrics, has organized a company under the title of William G. Isbell & Company, and will represent the American Simplex, made by the Simplex Motor Car Company, of Mishawaka, Ind. The new concern will retain the old headquarters at 1413 Michigan Avenue, Chicago.

Indianapolis has a new concern in the selling trade, the Indianapolis Motor Car Company, with temporary headquarters at 114-119 Kentucky Avenue, and the following officers: A. W. Markham, president; R. A. Radle, vice-president and general manager, and Paul Smith, secretary and treasurer. The company will handle the Dragon and the Logan line of commercial cars.

The Renault Freres selling branch, of New York City, announces through Manager Paul Lacroix a new sub-agent for Renault cars—Louis P. McNamara, whose salesrooms are located at Broadway and Forty-eighth street. This is the fifth New York agency established in less than two years, the others being the Palais de l'Automobile, Brewster & Company, Demarest & Company, and Cryder & Company.

The Baker Electric Vehicle agency, with Guy R. Pierce as general manager, has closed a long lease on the new auto garage and salesroom at 1714 Michigan Avenue, Chicago, and from this location Baker elec-

trics will be disposed of in the future in that city. A complete new electric plant has been installed, and when the decorators have fully completed their work on the salesroom it will be one of the most elaborate stores on the avenue.

PERSONAL TRADE MENTION.

Clinton R. Mabley has entered upon his duties as general manager for the Importers' Automobile Salon, with offices in the new Bryant Park Building, Sixth Avenue and Forty-second Street, New York.

Orville Sprecher, formerly vice-president and superintendent of the Prest-O-Lite Company, resigned on June 1 to join forces with the Avery Portable Lighting Company, and will reside in Milwaukee in the future.

R. D. Aldrich has resigned his position as manager of the New York branch of the Rose Manufacturing Company to become sales manager of the Twentieth Century Manufacturing Company, 19 Warren street, New York.

Thomas F. Ahern, formerly of Cleveland, has been appointed general superintendent of manufacture for the Wayne Automobile Company, of Detroit. Mr. Ahern has taken up his residence in Detroit and entered upon the duties of his new position.

At a special meeting of the directors of the Joseph Dixon Crucible Company, of Jersey City, N. J., held May 31, to take action on the death of John A. Walker, vice-president and treasurer, George T. Smith was elected vice-president; George E. Long, treasurer, and Harry Dailey, secretary.

J. H. O'Brien, for the past year factory manager for the Wayne Automobile Company, Detroit, Mich., and prior to that time in a similar position with the Ford Automobile Company, of the same city, has just severed his connection with the Wayne Company, and though Mr. O'Brien gives no hint of his future plans, his long experience in the automobile building field makes it certain that he will be heard from in the near future.

A NEW THIRTY-TON TRUCK.

Detroit again comes forth as the sponsor of a novel commercial vehicle. It is a heavy truck of the heaviest kind, for, although its power plant only consists of a 40-horsepower gasoline motor, its weight all on is something like seven tons, and it is said to have a carrying capacity of approximately thirty tons, in addition to having some power still in reserve to draw a trailer or two. It is the invention of John E. Myers, of Sheperd, Mich., who has been at work on it for the past half year. The rear wheels are 52 inches in diameter by 20 inches face, and the front wheels are 44 inches in diameter by 14 inches face. The truck is to be shipped to Alabama.

HOPEWELL TIRE CASE PATENT.

F. B. Hopewell, of Hopewell Brothers, Cambridge, Mass., has just been granted what is claimed to be a basic patent covering the design of a spare tire case, such as is universally used for carrying extra shoes on the car. The patent is No. 854,215, and was issued May 21,

1907, and it is the patentee's opinion that his claims broadly cover an annular tire case, as the only limitation in the patent is that it must be an annular case, though not specially limited to being a continuous case.

Claim 1 reads as follows: "An annular tire case composed of material having at each edge a longitudinal pocket, and a cord in each pocket to retain the pocketed edges of the case in a circle smaller than the circle defining the circumference of the tire." The case thus being caused to fit the tire by tightening a cord which contracts the edges of the case to a diameter smaller than that of the tire. The case itself was illustrated and described in THE AUTOMOBILE of May 23.

TRADE PUBLICATIONS RECEIVED.

From the Gearless Transmission Company, Rochester, N. Y., is to hand the firm's catalogue of 1907 models. It is well produced in colors, with illustrations on every page, and deals with all the models manufactured.

Three interesting touring stories, descriptions of new models and news culled from various quarters, is the bill of fare of No. 26 of the Rambler Magazine, issued by the Thomas B. Jeffrey Company, of Kenosha, Wis. Though especially appealing to the Rambler owner, the magazine should be interesting to all automobilists.

A new booklet is out from the Firestone Tire and Rubber Company's headquarters, at Akron, Ohio, dealing in general with the various types of pneumatic tires manufactured by this company, and giving special attention to the Safety Universal rim. Illustrations explain the constructional features of the Firestone detachable, and a number of halftones show the operation of mounting and dismounting.

There is a particularly handsome appearance about the Thomas Flyer catalogue, issued by the E. R. Thomas Motor Company, Buffalo, N. Y. Excellent half-tone views of the Buffalo and Detroit works and of the different agencies throughout the country, complete and detailed views of the car and explicit text, unite to make it one of the best of trade catalogues. The half-tone illustrations of mechanical parts and the sectionalized views of the motors are particularly helpful to those wishing to obtain a good knowledge of the construction of the Thomas Flyer and the Thomas Forty.

AN AFTERTHOUGHT OF JONES'.

"A Past Performance" is the title of an artistically executed little brochure from the Publicity Press concerning an event that has long since gone down the line into history, reckoning at the speed at which automobile history is made. To the ninety and nine who responded to the glad call, it will bring back a pleasant reminder of an evening well spent, and to the one who didn't, a wish that he had cut it out, whatever it happened to be, and attached himself to the gay bunch that went on the special with "eighteen speeds forward and no reverse"—to the place that is "forty-five minutes from Broadway"—the Jones Speedometer Factory at New Rochelle. It was hardly necessary to add that last, for every man who got

there recalls the day, date, time and place, while those who got bids and didn't materialize have been hearing of it ever since. The little book is a fitting commemoration of the event.

INFORMATION FOR AUTO USERS.

Gauntlet Monograms.—In addition to the already widely varied line of monograms turned out by the J. W. Colgan Company, Boston, Mass., this firm is making a specialty of some neat designs to be applied to automobiling gauntlets, samples of which are illustrated by the

COLGAN'S MONOGRAM GAUNTLETS.

accompanying cut. This, of course, only shows two designs, there being quite a variety. In connection with the addition of this new line, these makers have just issued a 32-page catalogue showing some of the many purposes for which they make monograms in all styles, such as for automobile radiators, medallions for robes, fittings and the like, as well as a variety of special insignia, trade marks and similar pieces.

"Caterpillar Flame Coils."—This is the rather unusual name given by the Pfanstiehl Electric Laboratory of Worth, Chicago, Ill., to their line of dashboard jump-spark coils. The peculiar wormlike appearance of the discharge of the coils in question, which is claimed by the makers to give a maximum of efficiency in operation on a minimum current consumption, is responsible for their title. In addition, these coils possess numerous other advantages, such as an extremely rapid and silent-working vibrator, which, taken in connection with an electrical design that eliminates the objectionable sparking at the vibrator points, combine to make as close an approach to the autoist's ideal of a troubleless coil as it is possible to turn out. These results are obtained by methods covered by American and foreign patents and an accurate balancing of the primary and secondary windings. The latter is wound in 14 sections, and is of unusually large wire. The sections are connected in pairs, and are thoroughly insulated so as to be proof against

excessive overloads. The primary is wound with much finer wire than is ordinarily employed on induction coils of this type. The coils are all made on the unit system, and each unit is patterned after the large x-ray coils on which these makers have been experimenting for the past five years. It is possible to take x-ray photographs with any of the regular automobile type of units, using current at a potential of 10 volts, which is somewhat remarkable, and is evidence of the great intensity of the discharge. These coils are made for 1, 2, 4 and 6-cylinder motors, the illustration showing the twin type.

Michelin's Handy Tire Gauge.—*Plus un pneu est gonflé, moins il chauffe.* To the experienced tire user, this is an axiom. The better a tire is inflated, the less it heats. Simply because there is less opportunity for friction between its different parts and principally between the shoe and the inner tube. But how many drivers, even after considerable experience, can tell offhand when a tire is properly inflated? It was easy enough to test the old bicycle tire merely by attempting to compress it with the hand, but an automobile tire may be little more than three quarters inflated and still give no indication of it, especially when viewed with the car empty. On the whole there is probably nothing so important in the tire user's breviary as the matter of proper inflation, and to make this an easily ascertainable matter, Michelin et Cie have devised a neat and compact pressure gauge of which circulars have been sent to their U. S. agents, E. Lamberjack & Company, 31-33 West Thirty-first street. As shown by the illustration this is readily attachable to the valve by means of the quick adjustment type of screw. Once in place, the button on top is pressed to obtain a reading, the dial being calibrated in kilos. And, say the makers, exhaustive tests have shown that a tire carrying 5 kilos pressure, which represented its proper degree of inflation, lasted three to five times as long as the same size tire inflated to 2.1-2 kilos and run on the same car under the same conditions throughout the length of the test.

TWO-CYLINDER PFANSTIEHL DASH COIL.

THE AUTOMOBILE

FLORAL ARCHES WERE ERECTED IN EVERY VILLAGE ON THE COURSE.

HOMBURG, GERMANY, June 14.—Felice Nazzaro, on a Fiat machine has captured the German Emperor's Cup, which all day long has been invitingly displayed to contestants and observers on the royal grandstands at Kloster Thron. His time for the four rounds of the 125-kilometer sinuous mountain circuit was 5:34:26, which is at the rate of 55.5 miles an hour. Considering the extraordinarily difficult nature of the course, the time is remarkably fast. Two years ago on the Auvergne circuit, which in the matter of turns and grades presents much similarity with the German course, Thiéry averaging 48.7 miles an hour for about the same distance; as the machines in the German race are lower in power than those engaged in the Gordon Bennett contest, the conclusion to be drawn from the comparison is a decided increase in the efficiency of the racing automobile of 1907 over that of 1905. On the Taunus circuit of 1904, much easier than this year's course, Thiéry's average, then considered very fast, did not exceed 59 miles an hour.

Second position in the German Emperor's race was secured by Hautvest, a Belgian who has won fame in touring competitions in his own land, but who has not previously figured in international speed tests. His Pipe machine, also a Belgian, was but four minutes 44 seconds slower than Nazzaro's Fiat. Michel, on an Opel machine of German origin, secured third position, but thirty-nine seconds behind the Belgian. Fifth and sixth positions have been secured respectively by Wagner and Lancia on Fiat racers, thus making the premier Italian factory the most successful in the contest. Henry Fournier, the ex-champion of France, who has returned to the racing game after an absence of several years, secured eighth place in an Itala, an Italian car of which he is the exclusive Paris selling agent.

Owing to the large number of entries, the race for the German Emperor's Cup was run in two stages, a preliminary on Wednesday to select forty to compete in the final, and the decisive con-

test on Thursday. Thus there were never more than forty machines on the course at once. Two rounds of the circuit only were run on the first day, and four in the final. France, Italy, Belgium, England, Austria and Switzerland were the nations engaged; America had no representatives. Heavy rain had made the course dangerous on the first day, and one fatal accident had to be recorded. For the final, however, the roads had become thoroughly dry, and all passed off satisfactorily.

The royal party, which assembled before 6 o'clock at the grandstands erected at Kloster Thron, comprised Emperor William, Prince and Princess Henry of Prussia, the Grand Duke and Duchess of Hesse, Prince Frederick Charles of Hesse, and other notables from the court. Thousands of spectators, brought to the scene of the race by special excursion trains, watched the contest, which was full of interest from start to finish.

At the end of the first round a German car was leading in 1:27:17, with Hautvest, the Belgian, close behind and Nazzaro third. At the end of the third round Hautvest was first, his time being 4:15:46. Nazzaro, however, was pressing him close, and on the last round forged ahead and captured the cup by the narrow margin of four minutes forty-four seconds. The prize consists of the Emperor's Cup, a vase and a table centerpiece from the royal porcelain manufactory at Charlottenberg.

Only two international races have been run in Europe this year, the Targa Florio and the German Emperor's race, in both of which Felice Nazzaro has been victorious. Last year he was second to Szisz in the French Grand Prix, and has twice figured

NAZZARO WEARING HIS HAPPY VICTOR'S SMILE.

NEAR SETTAMBOURG, WHERE THE RACERS WENT ALL OUT.

in the Vanderbilt Cup races. Nazzaro's racing career commenced in 1900, when he was mechanic to Lancia; for some time he was chauffeur for Vincenzo Florio, the donor of the Florio Cup. Up to this year he has never secured first position in any international event, though having driven in all of them.

URSEL'S NARROW STREETS CALLED FOR SKILLED DRIVING.

This second decisive Italian victory has considerably raised the chances of Fiat securing the Grand Prix, to be run in less than three weeks' time. Nazzaro, Wagner and Lancia are public favorites, as is indicated by bets on the race, even French sportsmen regarding their chances of victory as exceptionally bright.

START OF THE HERKOMER 1,140-MILE TOUR

LINDAU, GERMANY, June 8.—We have just finished the first three stages of the monster German endurance contest for the cup donated by Professor Von Herkomer, the auto-loving artist. Altogether the 198 machines furnished by Germany, Italy, France, Belgium, England and Switzerland are called upon to cover 1,140 miles on a closely calculated time schedule, to climb a few hills, give a good display of speed, show that they are comfortable and elegant, do not drink up too much water, have good tires—in short, to do all that an automobile can reasonably be expected to do. It is a complicated contest and one needs something of the Teutonic in his constitution to thoroughly understand the technicalities of the event.

Dresden, Saxony's ancient capital, was alive with automobiles the two days preceding the commencement of the tour. There seemed to be enough for every inhabitant, and certainly every inhabitant was as enthusiastic as if he owned one. At the Exhibition Palace there was a record crowd of royalty and dignitaries of every degree, and owners and chauffeurs chattering every language known to Europe.

Sharp-eyed officials pounced upon a bunch of machines, the bodies of which they declared had been doctored; ten Opels, fourteen Adlers and several Mercedes being told to retire on account of coachwork which contained too much aluminum under glossy layers of varnish. After protests, discussions and explanations the Opel and Adler heretics were allowed to run unofficially. The Mercedes were taken back into the fold, but the others, despite the vehement protests, were forced to remain in what was dubbed the "excommunication chamber." Twice Sorel and his French machine were sent away, once to have the road wheels completely varnished, and another time to repair a neglected detail of body work.

Altogether there were 134 official starters, but about thirty machines followed the tour though not recognized by the committee as competitors. Three ladies drove contesting machines: Miss Dorothy Levitt a six-cylinder Napier, Madame Lehmann a Metallurgique, and Madame Lili Sternberg a German machine. Sorel on a Lorraine-Dietrich led the procession—or, more correctly, he followed the official patrol car—and arrived first for lunch at Leipzig. At Eisenach, the end of the first stage, 225 miles, nearly all reported safely. Among the exceptions were

a Bianchi, which overturned outside the city, a Berliet which demolished a wall, a Porthos and a Beckmann in collision. Flowers, music and hurrahs greeted the competitors along the entire route, and native enthusiasm was shown everywhere.

At seven o'clock 142 machines started out from Eisenach for Mannheim, 210 miles distant, through picturesque valleys which we were unable to enjoy by reason of an annoying drizzle continuing to the lunch hour at Wurtzburg. There the sun broke through and the rest of the journey was magnificent. Dr. Rudolph Stoess, last year's winner, abandoned during the morning as the result of an accident to his steering gear. The car ran violently into a stone wall, with happily no injury to passengers. A 70-horsepower Stoewer—No. 13—driven by its owner, took a turn too quickly and capsized, the car being completely demolished, but the occupants free from injury. Sorel's Lorraine-Dietrich caught fire and was so seriously damaged that the loss of time in effecting repairs destroyed all chance of winning.

Through the Black Forest and along the borders of the Rhine was a magnificent run, enjoyed by all. One hundred and twenty-eight machines checked into Mannheim, the first one behind the pilot car being a Mercedes, driven by M. E. Landenburg, who won the trophy in 1905. In order to put down inconsiderate driving, five machines were disqualified for having caused accidents to other cars or users of the road.

Mannheim to Lindau, with a stop at Frenndstadt for lunch, comprised the third day's run of 232 miles. Good roads all the way, with some picturesque bits along the banks of Lake Constance, allowed of easy going. Two machines, however, dropped out of the morning run, and in the afternoon a number of accidents had to be recorded. A workman trying to save his dog from a car was himself knocked down and injured, a child was injured by a Porthos machine, a Bianchi ran into the parapet of a bridge, an Opel collided violently with a house and an Adler received serious injuries as the result of an encounter with a trolley car. Total number of arrivals at Lindau is 124.

Saturday night we shall reach Munich, remaining there all Sunday, Monday night we shall travel to Augsburg, undergoing a speed test en route, and on Wednesday evening we are timed to reach Frankfurt, where there will be a banquet, meeting of the jury, distribution of prizes, speeches, etc.

CLEVELANDERS HOLD CLIMB ON STUCKY HILL

CLEVELAND, June 17.—In spite of two postponements the annual hill climbing contest of the Cleveland Automobile Club pulled off Saturday was a tremendous success. As stated last week the property owners along the old hill at Gates Mills raised objections at the last moment and the club had to call the event off and cast about for another hill. Secretary Goddard, of the Cleveland Automobile Club, spent the greater part of the week scurrying about the countries within fifty miles of Cleveland looking for hills, and he finally located a good one.

The incline bearing the inelegant name of Stucky Hill is located thirty miles east of Cleveland on the road to the village of Chardon, a location which comes about as near being off the map as any place within a hundred miles of the Ohio metropolis. Not only was it a good hill, but it answered another important requirement in that it was so far removed from civilization that there are few people to complain if the dust was stirred up and the speed limits exceeded. City people who were unfortunate enough not to secure a seat in an automobile had to take the trolley line to Chardon and then drive—or walk—four miles to the hill. The villagers did what they could to provide transportation in the shape of farm wagons, hay ricks, etc., but the facilities were inadequate.

There were no objections from the country people. In fact, it proved an event which will long be talked about by the simple ruralties of Geauga County. The farmers for miles around laid aside their work and drove to the hill.

Timing and Other Arrangements Were Excellent.

The hill was a good one, about 7-10 of a mile long, fairly straight and made up of a series of pitches, there being three quite steep ascents, interspersed with long grades not so severe and lined with steep banks, which were fairly covered with the crowds. The club spent several hundred dollars in leveling off the rough spots and widening certain places, and in this they were assisted by the farmers who were very friendly.

The facilities for timing were perfect. In addition to the telephone line stretched over the course, a chronograph furnished by the Warner & Swasey Company, of Cleveland, manufacturers of astronomical instruments, was brought into play. This device gave a written record on a roll of the time each car spent in making the ascent. The outfit was situated at the finishing tape in a covered stand erected for the purpose. It was operated by and in charge of Walter Baker, of the American Ball Bearing Company, through whose courtesy it was provided.

The public interest shown in the event was evidenced by the fact that the Cleveland afternoon papers strung special wires from the hill to the village of Chardon, where operators were placed and repeated the reports, over other special wires by way of

Painesville, fifty miles to Cleveland. In spite of the terrific bursts of speed by some of the larger cars, there were no accidents.

The contests themselves were faster and more interesting and exciting than at any previous Cleveland contest. Walter White, in a special White steamer, wrested the honors for best time from the Stearns people, who in previous years have vanquished all comers in Cleveland events. But the Stearns people partly satisfied themselves by taking the cream of the events for stock cars of the heavier class. In his first attempt Walter White made the ascent in 58.5 seconds, and it looked like easy money for the big Stearns six cylinder, which had just been brought out. But on his second attempt White brought out another car, almost a duplicate in appearance to the famous "Whistling Billy" of track racing days. Nearby spectators said White's steam dial showed 1,600 pounds when he opened the throttle, and the car fairly jumped into the air. It was the quick starting of his car that gave White the advantage in every event. At hardly any time were the four wheels on the ground at once, and the judges at the finish estimated that the White demon was going ninety miles an hour when she crossed the tape on the comparatively level stretch approaching the finish. Frank Stearns did not drive his own car this year, but Frank Leland and C. Schilpp divided honors with the Stearns machines, both winning firsts, the former driving the new six-cylinder to victory. A. L. Campbell, in the Darracq of Vanderbilt Cup fame, covered the course in 51 seconds in the eighth event, but met with an accident in the free-for-all, while in the handicap he did 54. Herbert Lytle and E. Grady sent Pope cars up the hill in less than a minute. M. J. Roseboro, of the Ford Company, met with the greatest success of the day, winning three firsts, victories going to the six-cylinder roadster, the six-cylinder touring car, and the four-cylinder runabout. Henry Ford, of the Ford Company, went home jubilant after a remarkable afternoon's work. The Reo finished first in its class, but was deprived of another victory by the action of the committee in disqualifying one of the cars on the claim that it was out of its class. Jackson cars, under various drivers, carried off four firsts, and might have won a clean score in all starts had not C. M. Paxton met with a slight accident. The Stoddard-Dayton, in the light runabout class, won easily from a good field. The special event in which the Baker electric participated proved that an electric can be a remarkable hill-climber.

There were more than the usual number of protests. A Reo was ruled out in the second event and a Ford declared the winner. A Stoddard-Dayton protested against a Jackson in the fifth event, and these and other protests are still under consideration. The summaries follow:

AMATEUR CHAMPIONSHIP.

1. Stearns; driver, W. F. Hart.....1:20
2. Reo; driver, Al. Engel.....1:39

WALTER WHITE IN WHITE STEAMER STARTING RECORD CLIMB.

M. J. ROSEBORO AND HENRY FORD IN PRIZE-WINNING FORD.

A. L. CAMPBELL BRINGING THE DARRACQ UP THE STIFF GRADE.

STOCK RUNABOUTS UNDER \$850.	
1. Reo; driver, McGinnis.....	1:36 1-5
2. Ford; driver, A. B. Manley.....	1:49 2-5
STOCK RUNABOUTS UNDER \$1,500.	
1. Jackson; driver, Robert Burman.....	1:38 3-5
2. Reo; driver, C. R. Thomas.....	1:44 4-5
STOCK TOURING CARS UNDER \$1,500.

2. Reo; driver, Al. Engel.....	2:08 1-5
STOCK RUNABOUTS UNDER \$2,000.	
1. Jackson; driver, R. Burman.....	1:32 4-5
2. Stoddard-Dayton; E. C. Ireland.....	1:32 4-5
STOCK TOURING CARS UNDER \$2,000.	
1. Jackson; driver, Robert Burman.....	1:34 1-5
2. Reo; driver, McGinnis.....	1:37 7-10
STOCK RUNABOUTS UNDER \$3,000.	
1. Ford; driver, M. J. Roseboro.....	1:13 1-5
2. Stoddard-Dayton; driver, E. C. Ireland.....	1:32 1-5
3. Jackson; driver, R. Burman.....	1:37 3-10
STOCK TOURING CARS UNDER \$3,000.	
1. Ford; driver, J. Kubeck.....	1:21 7-10
2. White; driver, Sculfe.....	1:27 9-10
3. Pope-Hartford; driver, J. Grady.....	1:29
STOCK RUNABOUTS UNDER \$5,000.	
1. Stearns; driver, F. Leland.....	1:03 3-10
2. Stearns; driver, W. F. Hart.....	1:13 1-5
STOCK TOURING CARS UNDER \$5,000.	
1. Stearns; driver, C. Schlipp.....	0:57 1-10
2. Pope-Toledo; driver, H. Lytle.....	0:58 9-10
3. Pope-Toledo; driver, R. Magoon.....	1:06 1-5
STOCK CARS OVER \$5,000.	
Stearns; driver, F. Leland.....	1:11 1-10
PISTON DISPLACEMENT, TWO CYLINDER.	
1. Jackson; driver, R. Burman.....	2:33
2. Jackson; driver, C. D. Paxon.....	2:33
PISTON DISPLACEMENT, FOUR-CYLINDER.	
1. Darracq; driver, A. L. Campbell.....	0:54 4-5
2. Stearns; driver, C. Schlipp.....	0:56
3. Pope-Hartford; driver, J. Grady.....	1:01 9-10
4. Pope-Hartford; driver, H. Lytle.....	1:03 3-5
5. Pope-Toledo; driver, R. Magoon.....	1:04

FRANK LELAND AND HIS STEARNS SIX THREE-EVENT WINNER.

6. Stoddard-Dayton; driver, A. Brooks.....	1:23
7. Stoddard-Dayton; driver, E. C. Ireland.....	1:32

Actual winners not yet decided by technical committee.

PISTON DISPLACEMENT, SIX-CYLINDER.	
Stearns; driver, F. Leland.....	1:14

CARS FROM 851 TO 1,432 POUNDS.	
1. Stoddard-Dayton; driver, A. Brooks.....	1:28 7-10
2. Reo; driver, J. McGinnis.....	1:36 1-5

CARS FROM 1,432 TO 2,264 POUNDS.	
1. White; driver, Walter White.....	0:47 2-5
2. Darracq; driver, A. L. Campbell.....	0:51
3. Pope-Hartford; driver, H. Lytle.....	0:59 3-5

FREE-FOR-ALL.	
1. White; driver, Walter White.....	0:48 7-10
2. Stearns; driver, F. Leland.....	0:52 9-10
3. Stearns; driver, C. Schlipp.....	0:57 3-10

SPECIAL FOR ELECTRICS.	
Baker; driver, Greunfeld.....	1:41 1-2

JERSEY'S HILL CLIMB TO BE REVIVED.

Ever since that annual Jersey fixture in the shape of the Eagle Rock hill-climb became a thing of the past through force of circumstances, there has been a demand for an event of this kind. Old Eagle Rock was a terror at first, but soon it became child's play to the modern car, so that it was far easier to talk hill climb than it was to find a bump that would be worth tackling. "Senator" W. J. Morgan thinks he has found it, though, in Schooley's Mountain, which was recommended to him origi-

"S" TURN ON SCHOOLEY'S MOUNTAIN, MORRIS COUNTY, N. J.

nally by Jefferson De Mont Thompson, of the A. A. A. racing board, as a most likely place. The grade is situated in Morris County, N. J., between Germany Valley and Hackettstown, and starts from the former village. It is 1 1-2 miles long, has three sharp turns in it, one of them a right angle, and is said to be the stiffest of its kind that Jersey can boast. At present it is liberally studded with water-breaks, but the inhabitants of both places are enthusiastic over the affair and have agreed to supply several carloads of crushed stone and clay to repair bad spots.

The "Senator" recently made a trip to the scene of coming conflict with a party of autoists and it has been decided to hold "The National Hill Climb" there on July 4. The hill is reached from Newark via Elizabeth, Chatham, Madison, Morristown, Mendham and Chester on fine roads, and the scenery alone is said to be well worth the trip. Entry blanks for the climb are now out and can be had from W. J. Morgan, Bretton Hall, Eighty-fifty street and Broadway, New York. The classes are as follows:

1. Stock cars, \$1,000 or under, gasoline power.
 2. Stock touring cars, costing \$1,500 and under, gasoline power.
 3. Stock touring cars, costing \$2,500 and under, gasoline power.
 4. Stock touring cars, costing \$3,500 and under, gasoline power.
 5. Stock touring cars, costing \$5,000 and under, gasoline power.
 6. Free-for-all stock touring cars, all powers.
 7. Stock touring runabouts, 30-horsepower and under, gasoline.
 8. Stock touring runabouts, 30-horsepower and over, gasoline.
 9. Stock touring cars, costing \$2,500 to \$4,000, all powers.
- MOTORCYCLES—THREE CLASSES.
10. Engines having not over 500 cc. piston displacement.
 11. Engines having not over 1,000 cc. piston displacement.
 12. Free-for-all.

ALL READY FOR THE START OF THE PARADE IN FRONT OF CHARLES M. SCHWAB'S RESIDENCE ON RIVERSIDE DRIVE.

THERE was a lot more joy in the loud seething tide of the great city, Wednesday, June 12, than on ordinary days. A kindly thought of "Senator" W. J. Morgan, a couple of years ago, put into motion a sympathetic wave which has spread to distant cities of the States and is even being felt in the far-away capitals of Europe. It was the New York Motor Club on Manhattan Island and the Long Island Automobile Club across the stream which undertook, with contagious enthusiasm, the material organization of the joy-giving thought. If Chairman S. A. Miles, upon whose shoulders the burden of the preliminary work fell, and who deserves great credit for unselfish devotion to his task, felt heavy and tired at the end of the day, and if those who deprived themselves of their cars from morn till night felt footsore, it was all forgotten in the remembrance of the happy two thousand orphans who were brightened by a visit to Coney's wondrous charms.

Joy began at 8 o'clock in the vicinity of Seventy-third street and Riverside Drive—more correctly its public demonstration began there, for many an orphan cot had held a restless head unable to slumber at the thought of the morrow's feast. Chairman Miles established his headquarters at the Hotel Chatsworth and got into telephonic communication with each of the institutions supplying the youthful guests. An usher was dispatched to each "Home" to report to the starting point how the cars were filling and how arrangements were progressing at his point of observation. There were a number of eleventh-hour repentants, whose cars were dispatched to pick up a load at the points most needing help, according to information sent over the wire by the ushers. When the report came through: "All well, last car left," from the

orphans' homes, the long procession was put into movement, a police patrol at its head, busy Chairman Miles and his committee in an advance-guard runabout, and a long string of 147 bedecked automobiles crowded with happy bits of humanity. Down Broadway to Brooklyn Bridge mounted police set a modest pace, while "General" Miles kept in touch with his moving army by means of an efficient motor-cycle corps which ran up and down the line of march with messages and reports. Over the bridge police motorcyclists replaced the horse-men; thus there was no scorching, no rush, just an orderly procession that moved along without a hitch. There was a puncture, but before the juvenile tears could flow a motor scout had run down the line and brought up one of the two empty reserve cars into which the youngsters were transferred. There was a lesson in the way the machines responded to the call for a six-miles limit for such a long distance, without any sign of overheating.

Franklin had the honor of being the most strongly represented in the run, Maxwell, Pierce, White, Packard and Locomobile following in numerical importance. Six commercial vehicles, two of them Packard delivery wagons, furnished by the Adams Express Company, one Logan, one Knox, an electric truck and a Fifth avenue 'bus attracted considerable attention with their loads of boisterous boys. A big Berliet with Arthur N. Jervis in charge, had a valuable consignment of 1,200 boxes of candy on board, the gift of J. A. McClurg. The car returned safely to New York, but never a bit of the candy again saw Broadway. Mrs. H. A. Lozier, who drove her own car with a lot of youngsters in it, was the only woman driver in the New York delegation. Samuel Brill, of the Automobile Club of America,

CHAIRMAN MILES WAS ACTIVE.

ANXIOUSLY AWAITING THE ARRIVAL OF THE AUTOS.

ORPHANS ARRIVE AT CONEY ISLAND IN FRONT OF DREAMLAND.

entered heartily into the spirit of the affair, and tied to the back of his automobile a sign reading, "Orphans' Day, To-Day Dreamland for Ours; To-night, Dreamland for Hours."

While the assembly was forming and proceeding oceanward from Riverside Drive a similar gathering was being formed over on Long Island, the number of orphans there being between seven and eight hundred. Some of them had a long journey, one party in particular coming from the Otilie Orphanage, at Jamaica, in ten cars. A Stevens-Duryea machine came all the way from Amityville. Mrs. A. M. Seaman and Mrs. Cuneo were the women drivers of the Long Island section.

New York's orphans drove direct to Dreamland, where a substantial meal was provided for them by the Harrolds Motor Company, of New York, and the George N. Pierce Company, of Buffalo. Naturally James A. McClurg's candy disappeared like ice under a summer sun. Brooklyn's fatherless youngsters were whirled along Surf avenue to Feltman's, where an army of waiters dispensed substantial meals, followed by ice cream and all sorts of dainties.

It was only necessary to be a wearer of the distinctive orphan badge to have all the gates of Coney Island swing open as if by magic. Airships, shooting the chutes, the Bay of Naples, miniature Switzerland, Bostock's wonderful animals, Kansas Cyclone, the Days of Forty-nine, and a host of others, were as free as the air and were enjoyed to the full, with repeat visits to those which delighted juvenility voted as extra fine.

"Al" Reeves came along and said, "Who wants ice cream?"

There was a fifty-throat yell of "Me! me! me!"

While the first batch was gobbling and chattering another child-lover "stood treat" to a second batch; a third did likewise, and a fourth followed suit. If any child remained ice-creamless it was because of a perverted taste.

It had to come to an end, as all good things do, and at five o'clock the little ones scrambled into their autos and were driven to the various institutions which shelter them. Not one accident and not a hitch. The arrangements would have been hard to improve upon.

"The car has not a scratch on it," said the enthusiastic owner of a new touring automobile. "I never saw a better behaved set of

children in my life. They shall certainly have the machine next year."

Speaking of next year, the children will probably not go to Coney Island, but will be given a longer ride into the country and a wild romp in the fields. More nature and less ice cream may be the diet for the fatherless, hundreds of whom have never been out of the crowded city. Cars will not be lacking. Orphans' Day has proved itself such a success that no owner will want to keep his auto for his personal use on the children's fete day.

HOW THE QUAKERS CELEBRATED.

PHILADELPHIA, June 17.—For a first attempt the Orphans' Day ride provided by the Quaker City Motor Club, seconded by the Germantown and Philadelphia clubs and the two local women's automobile organizations, was a very creditable performance. Unfortunately there was not enough of it, but 103 machines responding to the invitation of Chairman George H. Smith. At least 200 had been expected, and 250 had been hoped for.

One feature of the affair which might have been improved upon was the failure to mass the cars either going to Willow Grove or on the return trip. Not that a parade would have added much to the pleasure of either guests or hosts; but the sight of more than a hundred automobile, whose owners had dropped business for a day to provide an outing for upward of eight hundred unfortunates, might have had a softening effect upon the thousands of local automobile owners who could not or would not assist.

As early as eight o'clock automobiles began to report to headquarters at the Hotel Majestic, and, after being supplied with numbers for their cars and from half a dozen to a dozen tags numbered to correspond, were dispatched immediately to the various institutions providing guests for the run. Each car was filled to its capacity, and the drivers, who had carte blanche to select their own route, only being required to report at Willow Grove at eleven o'clock, gave their living load as run-about a ride as time permitted.

The Rapid Transit Company of Philadelphia, which owns and operates Willow Grove, heartily seconded the automobilists' efforts by throwing open all the attractions of the place from 11 to 1 o'clock. A chorus of harsh "bonk-honks" at 1:15 called

WHERE THE LITTLE STOMACHS WERE FILLED TO POINT OF BURSTING.

COMMITTEE CAR THAT LED THE WAY.

the little ones from the attractions of the grove to a bountiful luncheon, where second helpings were the rule, not the exception. By 3 o'clock all had been gathered again into the cars and were flying cityward.

CROSSING THE BROOKLYN BRIDGE.

THE PRESS CAR CARRIED SWEETMEATS.

youngsters had the time of their lives in the run to White City and Sans Souci Park, where the management had made special arrangements for their entertainment. Frank L. Albert turned the place over to them, and for a few hours the mimic

WORCESTER AUTOISTS GAVE HEARTY SUPPORT.

WORCESTER, Mass., June 17.—The Worcester Automobile Club voted early in April to have its third annual orphans' outing on the day named by the A. A. A. at National Orphans' Day.

Forty-seven cars carried 329 orphans from St. Anne's Orphanage, St. Gabriel's Orphanage, Temporary Home and Day Nursery, Neighborhood House and Memorial Hospital around the city for an hour, then took them to Lincoln Park, at Lake Quinsigamond, where President Francis P. Dewey, owner of the park; J. W. Gorman, manager of the theater; J. P. Irwin and George Gett, representing the amusements, gave a hearty welcome to the motorists and their charges. After an hour of the charms of the park the children were taken for another ride around the city and then to their homes. Many of the leading business men of the city drove their cars in the run, while others sent their machines in charge of chauffeurs. All but two of the garages of the city were represented.

RAIN, BUT PLENTY OF FUN, AT CHICAGO.

CHICAGO, June 17.—It rained at Chicago on National Orphans' Day, but Chicago's thousand youngsters, in 125 automobiles, did not mind that. Three associations looked after the interests of the fatherless—the Chicago Automobile Club, the Chicago Motor Club and the Chicago Trade Automobile Association. Starting from the Auditorium Hotel early in the afternoon, the excited

steamer, shooting the chutes, the ice cream and the candy stalls had a strenuous life. Just as the sun came out for the first time in the day the youthful party was again embarked on the machines and trundled back to their homes. Alderman F. W. Taylor, from the Twenty-first Ward, acted as grand marshal of the day. In the eyes of the majority the most important official was Commissioner-General Richard Bacon, Jr., who appeared with a large auto truck piled high with crates of crackerjack and peanuts.

GRAND RAPIDS SUCCESSFULLY CELEBRATES.

GRAND RAPIDS, Mich., June 17.—Orphans' Day in Grand Rapids was a splendid success, in spite of the fact that when the machines left the asylums it was raining hard. Fifty big machines, enough to carry comfortably the 170 orphans of the city, were loaded by two o'clock, and the eight-mile run to the Cascade clubhouse was made without mishap. The children were there given the freedom of the clubhouse, had games by the river, and were provided with a bountiful repast before their return. The committee in charge consisted of Dr. Perry Schurtz, Orin Stair and Dr. J. E. Meengs.

BALTIMORE HAS 175 CARS IN LINE.

BALTIMORE, June 17.—The orphans of the Monumental City were the guests of the Automobile Club of Maryland on Orphans' Day, when 175 cars were used for their entertainment. Refreshments were furnished at Electric Park.

HOW THE LONG ISLANDERS TRANSPORTED THE ORPHAN BOYS' BAND OF SIXTY-FOUR PIECES.

PREPARATIONS COMPLETE FOR THE GRAND PRIX

PARIS, June 12.—With but twenty days separating us from the Grand Prix, for that much-advertised event is to be run on the Dieppe circuit on July 2, the Sporting Commission has now got down to details of organization. Racing cars have not been seen on the circuit since the beginning of the month, and those tourists who wish to make acquaintance with the fast course have their speed ruthlessly cut down to thirty kilometers an hour by vigilant gendarmes.

Salting the course was not considered sufficiently reliable to keep down dust, and the more costly but more reliable method of tarring has again been resorted to. The work is now terminated, not without a little criticism, Szisz in particular being of the opinion that it might be more thoroughly done on the turns.

It will be promptly at six o'clock that Lancia, who has drawn No. 1, will be sent away, the others following at intervals of one minute, whether a car is passing the grand stands at the time or not. Being on the loop road, there is no danger of a new starter coming into collision with a machine finishing its first round. Arrangements are completed for placing soldiers around the course; 4,000 men from line regiments, 400 horsemen, 300 foot gendarmes, and 300 mounted gendarmes—a total of 5,000 troops—will be distributed around the circuit. In open portions of the country there will be a soldier every hundred yards on each side of the road, with much stronger forces in the villages and on the turns. Sixty commissaires, appointed by the A. C. F., will also be spread round the course to observe the enforcement of the rules. At least twelve temporary bridges and tunnels will be specially constructed to unite the inside with the outside of the circuit before and during the race.

The nine Sporting Commission racers to compete among themselves during the Grand Prix contest, will be started at nine o'clock and at intervals of five minutes. Not until five o'clock in the evening will the triangular course be again open to the public; even then no vehicle may travel, except in the direction in which the race has been run. At six P. M. the course will be entirely free to all comers.

There is every possibility of the Dieppe course being adopted as a permanent course for the races held by the Automobile Club of France. The question will be discussed at the next meeting of the committee. Under the present system of a new circuit every season the club is led to an enormous amount of expense, for, no matter how good the roads are, there is a certain amount of work to be done in building temporary bridges, barriers, grand stands, and widening and improving the road where necessary. Last year \$11,000 were lost on the Grand Prix, and the Gordon Bennett race in Auvergne was far from being a profitable affair.

Members of the Technical Commission of the A. C. F. have been paying particular attention to the effect of fast cars on the road surface, both on straight stretches and on the turns. A close examination of the course will be made the day before and the day after the race in order to obtain accurate information on the effects of tires at high speeds. Information thus gained will be particularly valuable to the parliamentary commission concerned with automobile regulations.

Though no official announcement has yet been made, it is generally thought that Bayard-Clément will not be represented in the Grand Prix, in consequence of the unfortunate death of Albert Clément. Darracq, who for a time appeared likely to be an absentee also, will be in full force. The accident which cost the life of Marius Pin, at Rambouillet a few days ago, only caused slight damage to the racing machine, and M. Hériot, the owner, has offered it to Rigal, who has accepted, to drive it in the race. In accepting the offer Rigal declared that he would give half his engagement fee and half of whatever prize money he gains on the race to the widow and children of Marius Pin. Caillois and

Demogeot are the appointed drivers of the two other Darracqs, though there is still the possibility of a change being made in the selection of Demogeot. With but few exceptions all the competitors for the Grand Prix, some of whom have been round the course thirty or forty times, are loud in their praise of the circuit. Jenatzy predicts an average of from 63 to 65 miles an hour, which opinion is generally shared.

RIVES BUSY ON NEXT FRENCH SHOW.

PARIS, June 12.—Gustave Rives, the master mind of the Paris Automobile Salon, has promised an interesting retrospective exhibition at the next show in the Grand Palais. The time is particularly opportune, for next year's show is the tenth in an uninterrupted line of succession, and will in consequence be particularly brilliant. Last year a retrospective cycle exhibition formed one of the attractions of the Salon, but the coming one, devoted to motors, boats and flying machines, is certain to surpass it in interest. Among the important relics already secured are the first tricycle and the first voiturette produced from the then tiny De Dion factory, the Panhard machine which won the Paris-Bordeaux race in 1895, Jenatzy's "Jamais Contente," a Renault voiturette victorious in the Paris-Amsterdam-Paris of 1898, racers having participated in the early road races of Paris-Toulon, Paris-Madrid and Paris-Berlin, in addition to a number of racing machines victorious in international contests. In addition to the racers will be a series of touring cars showing the progress made from the earliest attempts to the present day. Motor boats and flying machines will be represented in the same way.

An elegance competition, to be held during the show, will prove as interesting to private users as to manufacturers. Its object is to develop the production of comfortable, elegant town vehicles, free from vibration, smoke and noise, graceful in design, comfortable for travel and artistic in finish. Elegant town vehicles have been quite a feature of the Paris automobile industry during the past two or three years, engineers and body builders having combined to produce the highest grade of town vehicle, having all the *chic* of a costly horse turnout, with none of its shortcomings.

RUSSIA HOLDS A ROAD RACE AND A SHOW.

ST. PETERSBURG, June 10.—Twenty-seven machines—heavy racers, light cars and motorcycles, started on the 434-mile road race from Moscow to St. Petersburg, the first of its kind held in the country, and which was one of the outside attractions of the automobile salon held with so much success and enthusiasm in the Manege Michel. Starting from a point two miles outside Moscow, the first machine was sent away at 2 A.M., the others following at intervals of two minutes. A large crowd was present at the start, recalling somewhat the condition which governed the start of the ill-famed Paris-Madrid race. Fortunately, however, there were no accidents. For 200 kilometers the road was guarded by Cossacks, and gasoline and tire stations were placed along the entire course at intervals. The first half of the distance was over excellent roads, but the latter half was on tracks that caused considerable difficulty to nearly all the machines. Duray's average of 46.4 miles an hour and the 30-horsepower Charron's average of 37 miles an hour are good performances under such conditions. The following is the classified result:

Lorraine-Dietrich, Duray, 9:22:0 (average, 46.4 miles an hour).
C. G. V., Champoiseau, 12:53:0 (average, 37 miles an hour).
Fiat, Folkin, first in second class, 14:18:0.
Mors, London, 14:20:0.
Brasier, Schwartz, first in tourist class, 14:28:0.
Argus, Menoff, 15:7:0.
Darracq, Jemlitchka, 15:32:0.

EUROPEAN RAILWAY MOTOR CARS*

By B. D. GRAY, AMERICAN LOCOMOTIVE WORKS.

AS a result of continued and consistent experimentation, covering a period of four years or more, conducted by numerous English and Continental railways, the self-propelled railway car has been brought to such a degree of refinement that it has become an important and established factor in the transportation of passengers and light goods traffic. While its inception dates back many years—experiments along this line having been made as early as 1873—the successful development of the self-contained car is quite recent. Owing partly to the crudity of early designs, but largely to under-estimation of its possibilities and lack of appreciation of the necessity for frequent and rapid train service, and because the demands of the traveling public were not nearly so exacting as at present, the early experiments were probably premature; but the phenomenal growth of our large cities, the grouping of commercial interests, and the ever-present desire for home comforts, have removed residence districts from business centres and brought about the necessity for efficient suburban and interurban transportation facilities. Greater demands upon business men's time have likewise contributed to the necessity for rapid transit. The influence of metropolitan activity is felt in the smaller cities and provincial towns, and extends even to the most remote country districts.

In the United States electricity has been widely adopted as a motive power, and has met with marked success the demands for quick and reliable service. Electrification of existing steam roads and the building of new electric lines have not been taken up so generally in Europe, and it is therefore only natural that the engineers of those railways should look for the solution of the frequent service problem in a vehicle which might be adapted to existing conditions with no expenditure for equipment other than that for the vehicle itself. This condition of affairs probably influenced recent builders of motor cars in selecting steam as a motive power, although its predominance at the present time is due chiefly to its low fuel cost and great flexibility.

Numerous English and Continental railway companies have permanently established motor car service on their lines in different localities, with marked success. The practicability of the self-contained car for certain kinds of service can no longer be doubted, nor is its field so limited as might be generally supposed. One may see such cars operating on unimportant branch lines as feeders to trunk line trains; on main lines through thickly populated districts, carrying passengers and luggage to and from the more important towns served by express trains; on suburban lines in competition with both trolley cars and steam trains, on an entire railway system, where there is no other means of transportation except for heavy freight.

What the Adoption of the System Means.

Its adoption permits better service, with greater frequency, at lower cost of operation, than is possible with the ordinary steam train, comprising a locomotive and one or more passenger coaches or combination cars, the lower operating cost being due chiefly to decreased fuel consumption and a reduction in the train crew. Motor car equipment is cheaper to install than ordinary train equipment, therefore fixed charges on the investment are correspondingly less. Maintenance charges on rolling stock are about the same in both cases, but track maintenance is less where motor cars are used because of decreased weight.

As compared with electric railways for interurban service, where current is supplied from a central station, the relative economy depends chiefly upon the frequency of the service. Taking into account the cost of equipment, installation, operation, current losses, etc., it is fair to assume that where cars are to be

run at thirty-minute intervals or less the electric railway is the most economical, but where car or train intervals are greater than thirty minutes, the balance is in favor of the self-propelled car.

The London & Southwestern Railway was one of the pioneers in the movement for self-contained cars, and in 1903 placed a steam car on their line between Fratton and South Sea. This car was equipped with small cylinders and vertical boiler, and, while not capable of high speed or quick acceleration, the results obtained were satisfactory from the standpoint of economy of operation, and probably encouraged more than anything else other railways to take up this problem. This car has a total length of fifty feet and seats forty passengers. The cylinders are inclined, driving the leading pair of wheels only.

One of the most satisfactory cars in operation abroad at the present time is the one developed by Mr. Churchward, chief engineer of the Great Western Railway of England. In the neighborhood of sixty of these cars are in service on various parts of the Great Western system, and others are in course of construction. They combine to a remarkable degree many of those qualities essential to success—large seating capacity with only moderate weight, flexibility of control, reasonable speed and acceleration, reliability, low maintenance and fair operating costs. The boiler is of the vertical fire-tube type, with no superheater, supported directly on the frame of the power truck, and serving as a centre pin by transmitting the driving effort to the sills of the car through flat springs. It is enclosed within a compartment of the car body about fourteen feet long, which contains the coal bunkers, operating levers, etc. As the car is arranged to run in both directions and is controlled from both ends, a stoker is employed in addition to the driver. Aside from attending to the fire, it is his duty to regulate the cut-off when the driver is at the other end of the car, as only brake and throttle connections are provided there. The motor consists of two single expansion cylinders 12x16 inches, coupled direct to the rear driving wheels, which in turn are coupled to the front drivers. Air brakes are provided, the usual form of steam-actuated automatic pumps being used to supply the air. The water supply is carried in tanks hung beneath the car body midway between the trucks.

As an indication of the reliability and commercial success of these cars, the following instance of service conditions may be cited: Two motor cars and four or five trailers are used on the main line of the Great Western between Chalford and Stonehouse, a distance of about seven miles. The railway at this point runs through what is known as the Stroud Valley, a thickly populated section comprising in all about 40,000 inhabitants in the nearby towns and outlying districts. The motor car schedule provides on an average fourteen round trips per day (a total of about 200 miles), so arranged as to run these cars between through trains, both passenger and freight. There are ten stops in the seven miles, and the running time each way is from twenty-three to twenty-five minutes.

These cars are capable of a maximum speed of fifty-five miles an hour, although the average running speed is thirty to thirty-five miles an hour. Their maximum acceleration is about one mile per hour per second.

The original cost of the type of motor car shown in Fig. 1 is about \$9,000, and the cost of operation, aside from the guard's pay, is 13 cents per car or train mile, including trailers, for the service above referred to, the coal consumption being about 20 pounds per train mile.

An English Gasoline-Electric.

About three years ago the North-Eastern Railway of England put into service two "petrol-electric" cars on a short line running out from Scarborough. Owing to the fact that traffic on this line

* Extract from paper presented at the Indianapolis meeting of the American Society of Mechanical Engineers.

is heavy during the summer season only, these cars are laid up during the winter, and have, therefore, not been in continuous service. One gallon of gasoline to $3\frac{1}{2}$ car miles is claimed for them, but the maintenance charges must necessarily be high.

The power plant consists of a four-cylinder horizontal opposed Wolsley engine, $8\frac{1}{2}\times 10$ inches, 85 b. h. p. at 420 r. p. m., direct connected to a compound-wound separately-excited generator of 55 kilowatt capacity, which furnishes current to two 50-horsepower electric motors of the ordinary railway type, on the leading truck. The exciter, of 3.75 kilowatt capacity, is mounted above the main generator and driven by a belt from the flywheel of the engine. In addition to exciting the fields of the generator, it is used to charge a storage battery, which supplies current for lighting the car, starting the generator and gasoline engine, and for a small automatic compressor motor, which supplies air for the whistle. The battery and compressor outfit are suspended beneath the car body. The engine and main generator are very cumbersome and heavy, and occupy practically one-third of the total length of the car. The total weight, including 60 gallons of gasoline and about 100 gallons of cooling water, is 35 tons, of which 22 tons are carried on the power truck.

Radiating pipes located above the the engine room, and supplied with air by a horizontal fan, in addition to that due to the motion of the car, serve to cool the jacket water. For extremely warm weather, an additional coil extending along the roof is provided and pipes are also arranged inside the car to be used for heating in cold weather. Electric brakes are used, the current being supplied by the motors acting as generators. Controlling apparatus is provided at both ends of the car, and only two men are required to operate—motorman and guard. The wages paid are about 7 and 6 shillings per day, respectively.

The complications of this system, the multiplicity of parts, and the excessive weight give a rather unfavorable impression. The combined efficiencies of the generator and motors must of necessity be low, and their use can only be reconciled with the extreme flexibility of transmission necessitated by a large unwieldy gasoline motor. As this particular type of car has not been perpetuated by the original builders and users, it may be safe to assume that it is not entirely satisfactory. It is the author's opinion that its indifferent success is due to the enormous size and weight of the power plant throughout, as a number of cars embodying practically the same principles, but of much lighter construction, have been in successful operation in Hungary during the past three years.

Some Types on French Railways.

Numerous experiments have been made on the different French railways, including the Paris-Orleans; Paris, Lyons & Mediterranean; Northern; Western and the State railways, with various types of cars, but the most successful at the present time, and the one being almost universally adopted, is that of Purrey, of Bordeaux, and although differing in minor structural details, the power plants of the Purrey cars as built by the different railways are practically the same. There is also a slight variation in the size, weight, and arrangement of cars to best meet the requirements of the different roads, but that of the Paris-Orleans Railway is fairly representative of all the cars used in France.

The car body has a total length of about 60 feet, and seats 30 third-class passengers in three compartments, and 25 first-class passengers in 2 1-2 compartments. In addition to this, there is a baggage compartment at the forward end 11 feet 6 inches long and extending the entire width of the car, 112 inches. The forward end is pivoted on a power truck, the rear end being carried upon a single axle. The power truck, which carries the boiler, motor, fuel, water, etc., has two axles 126 inches apart, the rear wheels only being used for driving. The weight of this truck is 14 1-2 tons, of which about 7 tons is on the rear axle. The total weight of the car complete is about 35 tons.

The motor is four-cylinder tandem compound, high pressure 6 5-16 inches diameter, low pressure 8 11-16 inches diameter, and

the stroke 8 7-8 inches, rated at 260 horsepower at 650 revolutions per minute. A bypass valve is provided to admit high pressure steam to the low pressure cylinders for quick acceleration and unusually heavy pulling. Ordinary D type valves are used, operated through Stephenson link motion. In this design, the motor is attached horizontally to the frame of the car, and its power transmitted to the rear axle by two toothed chains of special construction, similar to the Renold and Morse silent type. All the working parts are enclosed in a dustproof case, and lubricated principally by splash. The motor is accessible through a trap door in the floor of the baggage compartment, and any ordinary adjustments can be made from this point. A door is also provided opening into the baggage compartment, through which the boiler tubes may be inspected, thus rendering the most delicate parts of the mechanism readily accessible. Should it be necessary to overhaul the boiler or motor, the power truck may be removed from the body of the car in 20 minutes and another substituted in its place. Westinghouse air brakes and hand brakes are used.

The Paris-Orleans road have 10 cars and 12 power trucks, and have been able to keep the 10 cars in service practically all the time by having the two extra trucks in reserve. As a rule, one or two trailers are attached to these motor cars, the average weight of the train being 50 tons. The fuel consumption for such a train is about 21 pounds of coke per mile.

This car is arranged to run in one direction only, except for backing up, and the crew consists of only the driver and one man in the baggage compartment, tickets being taken at the stations by inspectors. It is geared rather high, and is capable of running at a speed of about fifty-six miles per hour. Its acceleration, however, is not so good as that of the Great Western car.

The Orleans road has instituted a motor car service between Bourges and Saincaize, a distance of 59 kilometers (37 miles), the run being made in 70 minutes, including eight stops. Sufficient fuel and water capacity are provided for a run of 50 kilometers.

The Purrey system has been used for a number of years on different tramway lines in the city of Paris, but for this service it has been found that the single expansion engine gives better results than the compound, and also that there is no advantage in having a variable cut-off, owing to the frequency of the stops, the speed of the motor being controlled entirely by the throttle valve, no adjustments being necessary for starting.

Arad Csanadar Railway of Hungary.

One of the most interesting examples of successful operation of railway motor cars on a large scale is that of the Arad Csanadar Railway of Hungary. Three years ago a Ganz steam car was put into service on this road in an experimental way, and the results were so satisfactory that the management decided to replace their locomotive and train service, for passenger and light goods traffic, with the self-propelled car, and have gradually added to their motor car equipment until now they have a total of 37 cars of which 4 are Ganz steam cars 35 horsepower of the de Dion system; 22 are gasoline-electric 30-35 horsepower of the de Dion Bouton system, constructed by Johann Weitzer; 10 are gasoline-electric 70 horsepower of the de Dion Bouton system; one is gasoline 40 horsepower (German Daimler).

The total length of this railway is about 400 kilometers, single track, running for the most part through a sparsely populated agricultural district, where conditions are conducive to economical operations, as the average Hungarian peasant is not very fastidious nor exacting in the matter of luxuriously furnished cars or rapid transportation. Their cars are of very light construction, and, being run at low speed, require small power plants in which the fuel consumption is comparatively low. Only the heavy freight traffic is handled by steam locomotives, and in 1906 the motor cars covered a total of about 1,000,000 miles, in most cases hauling from one to four trailers.

The improved service offered by the motor car has stimulated traffic in that section to such an extent that within the past two

years it has doubled. One of the most remarkable features in connection with the success of this railway is the extremely low fares, which average about 1-3 cent per mile, and yet the road pays 8 1-2 per cent. on the investment of \$6,500,000 after paying 19 per cent. of the total receipts to the government as a tax.

The larger gasoline-electric cars used by this railway are equipped with a 70-horsepower gasoline motor direct connected to a 45-kilowatt generator, which supplies current to two ordinary railway type motors attached to the two axles. The usual series parallel controller is provided for starting. After the car is once under way, its speed is controlled almost entirely by the throttle of the gas engine. At the right of the electric controller are two smaller levers, one of which connects with the throttle, and the other with the spark advance mechanism. In addition to these, there is a small rheostat provided within easy reach of the operator, which serves to vary the field strength of the generator, and thus gives an additional means for controlling the car during the acceleration period. Controlling apparatus is provided at only one end of the car, as it is intended to run in only one direction except for shunting. Bocker air brakes and hand brakes are provided, air being supplied by a small compressor driven from the outer end of the armature shaft. An air whistle

the other supported elastically from the truck frame. Control is provided at only one end, and only one man is required to operate the car. The 35-horsepower car has a seating capacity of 22 first-class and 12 second-class passengers. Its over all length is about 35 feet. A speed of 35 miles per hour is claimed for this car with a fuel consumption of 5.3 to 7.2 pounds of coke per mile. The same consumption is claimed with trailers weighing from 35 to 40 tons at a speed of 12 1-2 miles per hour.

Details of the Motor.

Ganz motors are two-cylinder cross compound, the one used with the 35-horsepower boiler having cylinder diameters of 4 9-16 inches and 6 11-16 inches and common stroke of 4 3-4 inches. Two steam operated feed pumps are provided, one being held in reserve.

The 80-horsepower car has a total length of 46 feet, seats 47 passengers, weighs 23 tons, and is capable of climbing a 1.6 per cent. grade with two trailers weighing 12 tons each, at a speed of 25 miles per hour. One peculiar feature of the Ganz system is the double gear reduction between the motor and the axle. Two spur gears are mounted loose on the crankshaft between the two cranks and meshing with gears keyed to the axle. A jaw clutch

SECTIONAL ELEVATION OF GERMAN DAIMLER GASOLINE CAR THAT IS MUCH USED ON THE SMALLER GERMAN RAILWAYS.

is used. Acetylene gas is used for lighting. Coils are provided along the sides of the car for heating, the jacket water from the motor being used for this purpose. In warm weather the jacket water is passed through a coil of tubes on the roof at the forward end where it is exposed to the air.

The space occupied by the power plant is considerably less in proportion to the length of the car than that of the Great Eastern, although the systems are practically identical in principle. Its acceleration is very good indeed, and its maximum speed is about 35 miles per hour without trailer, and with two trailers about 25 miles per hour. More than two trailers are never used with the 70-horsepower car, as it is used for express service, but the smaller cars, equipped with 35-horsepower motors which run very much slower, frequently haul as many as four trailers. It is claimed by the engineers of this road that 65 per cent. of the motor's power is delivered at the wheels. In general very satisfactory results are obtained and the car is admirably adapted to their conditions.

The Ganz cars are manufactured in three sizes, 35, 50 and 80 horsepower. The general arrangement is the same in all three, the boiler being placed in a compartment at the forward end of the car, together with fuel bunker, feed pumps, and controlling apparatus. The motor is placed horizontally on the leading truck, and drives the rear axle through spur gears. It is supported in the usual electric railway motor style, one end being swiveled about the axle and

positively driven is provided between the driving gears, and so arranged as to engage either one or the other when moved along the shaft. The ratio of reduction is about 2 to 1. As a rule, the low gear is used when the trailers are attached and for heavy grades.

The Serpollet system differs from the Purrey and Ganz types chiefly in that the boiler is of the flash type, and kerosene is generally used as fuel. A very high degree of superheat is obtained, reaching even 1,200 degrees F., which, together with the incrustation attending the use of more or less impure water is conducive to the burning of tubes. The experience of the Paris, Lyons and Mediterranean Railway with this type of car has been rather unsatisfactory, because of tube troubles, and the Purrey car is now being adopted in its place.

The Komarek car, manufactured by F. X. Komarek, Vienna, and used to some extent by the Austrian State railways and several of its branches, is one of the most rational in design of all in use abroad. Its builders may have erred slightly on the side of weight, but it shows remarkable economy and unusual freedom from repairs and troubles of all kinds.

This car is capable of running at a speed of 25 miles per hour on a level while hauling trailers comprising a total of 50 tons. The operating cost is said to be about 5 cents per train mile exclusive of the guard's pay, with coal costing \$3.25 per ton.

In general, the arrangement of the four axle car is similar to

the Purrey with the forward end of the body supported on the power truck. Other types with two and three axles have the boiler in a compartment at the forward end of the car body, supported by the main body frame. The motor is practically a small cross compound locomotive with outside cylinders, driving on one pair of wheels only. A vertical water tube boiler of special construction is used. To provide for expansion, the inner shell is corrugated, and the tubes are accessible for cleaning and renewal through plugs and manholes in the outer shell. A superheater coil is placed in the upper part of the furnace, and heated by the exhaust gases, the degree of superheat averaging about 300 degrees F.

German Daimler Gasoline Car.

This type of car has been used in considerable numbers on some of the smaller German railways, notably the Württemberg State Railway and on the Swiss Federal Railway. It is a comparatively small car having a total length of 33 feet with a seating capacity of 36. It is equipped with a 30-horsepower Daimler four cylinder (5 1-4 by 6 3-4 inch) engine of the heavy slow speed type, its normal speed being in the neighborhood of 550 revolutions per minute. The motor is located practically in the middle of the car, projecting upward through the floor to a considerable height, and inclosed by a wooden box. It is rigidly attached to a sub-frame, on which the car body is supported by eight elliptic springs, the sub-frame being carried rigidly on the two axles. Power is transmitted from the motor through a leather-faced cone friction clutch, and through a sliding gear transmission, arranged to give four speeds and reverse, to one of the axles. Control levers are provided at either end of the car, by means of which the speed of the motor may be controlled, gear changes made, and also the direction of motion reversed. When the driver leaves one platform to go to the other, the gear levers are locked in a neutral position. Their connections to the gear case then serve as fulcrums for the operating levers and their connections at the other end of the car. The transmission is extremely heavy and the gears somewhat difficult to shift. They are not entirely protected from dust and therefore subject to rapid wear. The cone clutch requires considerable attention to secure smooth operation. If neglected, it takes hold with such brusqueness that jerking of the car results, to the extreme discomfort of the passengers. One of these cars has been in service on the Arad Csanadar Railway but has been practically abandoned because of the clutch and gear troubles.

Several years ago the Daimler Motor Company, of Coventry, England, built a number of small railway cars of the straight gasoline type, equipped with two 30-horsepower motors, carried on a sub-frame between the axles. They were placed at diagonally opposite corners of the frame, and a sliding gear transmission provided, centrally located and so arranged that either or both motors could drive through it, and thence through bevel gearing to the two axles. These cars have not been satisfactory because of clutch and gear troubles, and because they were rather expensive to operate, the fuel cost being high. The usual friction clutches interposed between the motors and transmission permitted the use of either one of the motors independently of the other, a feature which may possess merit in minimizing fuel consumption, and in being able to proceed with one motor if the other for any reason becomes inoperative. Two axle cars, such as the German and English Daimler, are not applicable to all kinds of service because of the long wheelbase, which is 15 feet 9 inches in the case of the former and 15 feet in the latter.

Some Remarks in Conclusion.

The author's impressions of the railway motor car situation abroad, gained from personal observation of the leading types herein described in operation, and from personal interviews with railway officials and others more or less directly interested, may be summed up as follows:

The field of the railway motor car is very broad indeed. It has always demonstrated its superiority over the ordinary steam train,

in making possible more frequent service at lower operating cost, as a feeder to express trains, on branch and main lines, in either very thickly or very sparsely populated districts. It has successfully competed with electric cars of both trolley and storage battery types, in suburban and interurban service. In the case of the Arad Csanadar Railway, it has replaced steam trains on the entire system except for heavy freight. Further refinement is possible and may be expected, which will extend its field of usefulness. Steam, as a motive power in cars of 80 horsepower or over possesses the greatest number of advantages, among which may be named flexibility, reliability and economical operation. First cost is also in favor of the steam car, and likewise to a slight extent maintenance charges.

For cars of less than 80 horsepower the internal combustion motor shows lower fuel cost than the steam car of like power. Present well-known forms of gear transmission with friction clutches which are entirely successful on gasoline automobiles are not suitable for heavy cars because of their inelasticity and the enormous difference in inertia of weights dealt with.

Electric transmission possesses the required flexibility and seems best adapted for the purpose.

A BANNER YEAR FOR AUTOMOBILE EXPORTS.

It is evident that 1907 is to be a record-breaking year in the exports of automobiles and that its total will top the \$5,000,000 mark by a substantial margin, for according to the last report of the Department of Commerce and Labor, the aggregate for the period of ten months ending with April, 1907, was \$4,104,737. As the total for the month of April alone represented \$686,144, there seems to be every possibility that the figures for the fiscal year will be nearer the six million mark than the five. No less than 397 complete cars were exported, of a value of \$638,014, the balance of \$48,130 representing the value of parts sent abroad during the same month.

The rate of growth may be appreciated by the fact that these figures represent an increase of more than sixty per cent over the total for April a year ago, which was but \$408,383, while some idea of the manner in which the exports have grown from year to year may be had from the figures of the periods of ten months ending with April in the past three years, which were \$1,876,063, \$2,473,207 and \$4,104,737 for 1905, 1906 and 1907, respectively.

Just where all these cars and the vast quantities of parts find a ready market is interestingly revealed by the detailed table, which moreover brings to light the startling fact that the bulk of the increase in American exports is to be found in the figures represented by the takings of those countries which are automobile producers themselves, and as such, strenuous competitors for the world's trade. For instance, both England and France show increases of considerably more than 100 per cent, and the difference is not merely one of percentages, as the amounts are substantial, as will be seen upon reference to the table. The same is true of other Europe, while both Germany and Italy show proportionately great increases.

The detailed table follows:

	April 1906	April 1907	Ten Mos. Ending 1906	April 1907
Automobiles, and parts of—				
Automobiles	408,333	\$688,014	\$2,437,207	\$3,603,298

GENERAL POINTERS FOR THE NOVICE OWNER

By CHARLES B. HAYWARD.

WEATHER conditions have been responsible for delaying it considerably, but it seems to be about due now if ever—that annual deluge of advice that is hurled at the head of the unoffending beginner. It is a hardy annual that does duty as a space filler year after year, usually appearing in much the same form, so that each succeeding crop of *don'ts* and *musts* are as like as grains of wheat from the same field, but the demand continues strong, nevertheless, which is easily accounted for by the largely increasing army of beginners that comes on the field each spring, anxious to devour every available bit of information to be had. The man to whom, the year previous, the technical pages of an automobile weekly were so much Sanscrit, is frequently the individual who develops such an amazing appetite for matters rudimentary concerning the handling and maintenance of his car that the demand for articles of one syllable, so to speak, is readily explained.

Naturally enough, about the first thing the proud owner wishes to know and familiarize himself with is the matter of breakdowns. Pride of possession and the smoothness of its performance at first banishes all thought of such a thing as the possibility of his dream of a car ever going wrong, but a little second thought as well as the sight of others in trouble soon brings with it a realization of the fact that automobile troubles fall on the just and unjust alike. Where to begin is really the question of greatest moment, for there are apparently so many things to learn that it is somewhat difficult to know just which line of investigation to take up as a starter. A pseudo-authority has calculated that there are thirty different things that can go wrong with a gasoline engine, and he took the trouble to tabulate them carefully for future reference, at the same time recommending to all who would learn to pay heed and, beginning at the top of the list, wade through the thirty, if trouble were to be speedily found. After a little experience, the novice will doubtless come to the conclusion that there are more apt to be three hundred things than thirty to go wrong about the engine alone, not to mention sundry other parts of the car, but he will hardly find it necessary to tabulate them nor try to give them a relative order of precedence, though such they have.

Care in Driving the First Requisite.

Starting in with a brand new car just as it comes from the makers, whose testing crews have put it in fine fettle, there is little need to worry about matters going wrong at first. The factor of safety where reliability is concerned, has been brought to a very high point in the modern automobile so that his first care should be to master the operation of the car. Volumes have been written on the subject and doubtless others are in preparation at the moment and they will always continue to come, so that it would seem as if it were hardly possible to say anything new on this matter of pressing importance to the beginner, other than to emphasize the word of caution usually given. With the first full realization of the power at his command, the novice is apt to become keen to use it and show his friends how fast his new car can travel. Changes of speed shade so imperceptibly into one another that before he knows it the car is beyond his control, and herein lies the chief danger. The experienced hand and eye frequently serve to avert disaster when it appears most imminent, where the novice when suddenly confronted with a situation that is the outgrowth of a bit of carelessness in going too fast, finds himself helpless. It would certainly seem an entirely superfluous bit of advice under such circumstances to throw out a caution about trying to make a car take a right angle turn at high speed. There are natural laws that will not be denied, and one of them is that a body traveling in a straight line has a tendency to maintain its direction of travel that is proportionate to

its velocity. The faster the car is going the more will it resent an attempt to suddenly change its direction; the result is invariably that it does continue in that direction, progressing sideways by rolls instead of on its proper base. The frequency with which accidents of this nature occur, shows how little the advice is heeded.

How Not to Leave the Car Is Important.

It is assumed in this case that when the newly-fledged autoist finally takes possession of his car from the agent, the latter has initiated him into all the mysteries of its operation. He knows how to start and stop as well as handle the wheel and the change speed levers whether in traffic or out in the open, so that it is really the little difficulties that are most troublesome. But before taking these up, it is well to dwell on a point that is seldom, if ever, brought out in any of the lengthy dissertations so full of valuable advice that are constantly appearing, and that is, *how not to leave the car*. To one who has watched new hands in the course of being broken in at the steering wheel, the first thing to strike the attention is the fact that nine out of almost every ten will go through the same procedure in bringing the car to a stop and leaving it, and that is in failing to return the change speed lever to the neutral point. The emergency brake will invariably be applied with great care and firmness, but the change speed lever will almost as many times be left in whatever notch it happened to be when the car stopped.

Novices are not the only ones who do this, as witness the occasional accident that results from it. That the latter are not more numerous is probably due to the fact that emergency brakes as well as their interconnections with the clutch mechanism, are usually well built and seldom fail to perform their functions. In other words, it is not the care of the driver so much as the reliability of the mechanism that serves to keep down the number of accidents. This, then, is one of the things that every beginner should impress upon his mind most forcibly when learning to handle a car, and that is, never to leave it in such condition that it can by any possibility start ahead should the emergency brake accidentally be released while the motor is running. The latter should invariably be stopped when the car is left standing, the change speed lever should always be brought back to the neutral point whether the car is to be left or not. Apart from the necessity of doing this to avert accident, going into the first speed to start is always requisite so that a shift would be necessary at all events.

Little Troubles That Are Perplexing.

It has been figured out as the result of a lengthy investigation into the subject that between them the carburetion and the ignition are responsible for 80 to 90 per cent. of all the troubles that afflict the automobile, and this will be borne out by the personal experience of the average autoist who runs his own car and doctors it when necessary. Doubtless the ignition can be accorded the first place as the inquiry referred to showed that it was accountable for fully 50 per cent. of all the involuntary stops while the matter of fuel supply provided 30 to 40 per cent., only a mere matter of 10 per cent. of all the troubles encountered being traceable to purely mechanical defections. This being the case, these essentials should be the first to come in for attention.

Take the ignition as a starter. Of course volumes can be written on it and still leave something unsaid, but in many cases the beginner is but little wiser after having waded through them. It is to be presumed that the newcomer knows the rudiments and further knows how to apply them. Next to these comes a knowledge of the system's weak points, and it is surprising how long it takes some new hands at the wheel to put two and two together when an ignition fault is in question. There seems to be little

doubt that the timer of the coil and accumulator system of ignition is the most prolific source of trouble, though this is something that it is hard to make the novice believe and something that it takes him a goodly time to realize for himself. To the average beginner there are only two things to go wrong about the ignition system and they are the spark plugs and the battery. Like the little girl who wore her tooth brush out on her two front teeth without touching the others, the beginner spends his time cleaning the spark plugs and testing the battery, probably running it down as much, if not more, in this way than in actual service. Of course, the timer is not always at fault, by any means—if there were any one thing about the ignition system that always could be relied upon as the sole source of trouble, matters would be greatly simplified. But it is responsible for a puzzling refusal of the motor to start in far more cases than it is suspected, particularly by the autoists whose experience in trouble-hunting has been limited. And by the same token, more spark plugs get an unnecessary cleaning than even the most finicky of old maids would give a prized piece of china. Plugs do soot and batteries run down—that goes without saying, but they are not things of one idea by any means. Take the average ignition in the best of condition and its timer will nearly always be found to constitute its weakest link.

There are other things beside, such as the ubiquitous short-circuit, the sticking trembler, the poor ground connection or a chafed secondary lead, but these and a great many others that might be mentioned, were it profitable to do so, are of rather rare occurrence on the modern car that is at all well taken care of. It is an axiom that moving parts wear quickly, and rubbing parts most quickly, so that attention to those parts subjected to the greatest wear, whether mechanical or electrical, is usually time well spent when looking for trouble.

Some Common Fuel Supply Troubles.

It would seem that the empty gasoline tank joke which so often was found to constitute the sole moving cause of what the fledgling took to be serious trouble indeed in the early days, should be catalogued as belonging to a prehistoric age in things automobile. That such a thing can happen to-day hardly seems possible, but the fact remains, as note the general demand for a reserve supply of fuel that cannot be used inadvertently by the driver. And the empty tank or its equivalent, which means lack of fuel, is at the root of not a few engine troubles that are traceable to this essential. Next to no gasoline, too much of it is the cause of much profanity. In fact, it is a far more common ailment than its opposite and all unknowing, the average green hand aggravates the trouble in nine cases out of ten. Failure to produce the welcome chug that means the motor is ready to assume its duties, calls for another whack at the carbureter and a return to the crank, the operations being repeated alternately.

I have often thought that a medal ought to be awarded to some of the well-known carbureter makers by virtue of the amount of abuse their devices will stand and still perform their duty. The way some drivers *tickle* the carbureter would cause an elephant's hide to itch; in fact, not a few seem to regard the little lever that touches the float as a sort of pump which requires vigorous battering to draw fuel up through the spray nozzle. Pressing it down as gently as if it were frail glass and holding it down momentarily will naturally accomplish the same object with far less risk of throwing the float out of adjustment.

There can be no denying the fact that there are some phases of the carbureter problem that are more than sufficient to puzzle the most experienced, so it is little to be wondered at that its vagaries should make it respected as a mystery by the less initiated, and because a thorough understanding of it is more or less rare it is looked upon as a proper subject for investigation by the amateur every time that there is anything inexplicably wrong with the motor. Which means, of course, whenever the motor refuses to start and frequent recourse to the crank fails to produce any encouragement. May be it is on the principle that some people

are always ready to torment anything that cannot kick back, that so many carbureter adjustments are gone through every time there is trouble of this sort. Certain it is that this part of the motor is tampered with all too frequently on little or no provocation until it gets out of order for good, principally because it has been bungled with so much. This and hammering on the carbureter pin to tickle it are quite common practices, as any autoist who keeps his eyes open may see for himself. Nor does the average beginner appreciate the fact that too much gasoline is almost as bad as none at all when it comes to starting the motor—a state of affairs for which overmuch persuasion of the carbureter to induce the fuel supply's arrival at it is most often responsible. It should be remembered that turning the motor over by hand induces but a comparatively small amount of suction through the air inlet and that in consequence almost pure gasoline vapor is drawn in. Anyone who has tried knows it is not an easy matter to fire this. If it were not for the fact that such a condition usually cures itself in the interval between tinkering by the evaporation of the gasoline and the formation of an explosive mixture, the average autoist would doubtless find his motor much harder to start than it is. An extra quick turn over compression is far more effective in creating the mixture requisite for the initial explosion than flooding the carbureter and when an encore or two at the crank fails of the desired result, momentary depression of the float will save both time and gasoline.

There is nothing startlingly novel about the foregoing suggestions, and the new hand who applies himself to the study of his car soon learns them for himself, not to mention a number of others equally valuable to him in the maintenance of his machine, but disregard of them on the part of the novice is very general in his early days and the fact that they are accountable for an amount of annoyance totally disproportionate to their apparent importance is seldom suspected. They are the little worries of automobiling and, like the little troubles of everyday life, they take on an appearance of great magnitude and importance at the moment. They stop the wheels of progress for the time being and when the ailment does not respond instantaneously to the first treatment that suggests itself to the self-constituted physician, he is prone to lay the blame on the machine instead of on his own lack of skill and patience in doing the doctoring.

IN CASE THE PRESSURE FEED BREAKS DOWN.

One of the disadvantages of a pressure feed gasoline tank under the chassis is the danger of it being pierced by a collision or by a flying stone thrown up by the wheels of the vehicle itself. There are a number of preventatives in general use. Some firms place a stout steel bar across the frame to the rear of the tank, thus preventing it being hit by any vehicle in the rear; a number of laths held together by a strap are sometimes employed, and a large sheet of matting is not infrequently seen. This latter is not to be recommended. It is easy to spill gasoline, which is of course sucked up by the mat, and should a light reach it a short time after a serious flare-up would result. Some European chauffeurs surround their tank by a sheet of fine wire gauze, which effectively keeps off road projections and does not retain gasoline. If a transverse metal bar is used in conjunction with this all danger of the tank being pierced is removed.

Should the pressure feed system break down, either owing to the tank being pierced or owing to one of the air pipes breaking, a temporary remedy can be obtained as follows: Disconnect the main feed pipe to the carbureter and replace it by a rubber tube about a yard long leading from the carbureter to the driver's seat. If necessary a hole could be bored in the footboard; care should of course be taken to keep the tube away from the moving parts. A curved piece of metal piping is attached to the end of the rubber tube, and the long end put into a tin of gasoline. The can may be attached to the dashboard, and as reliable a flow of gasoline is obtained as if the regular fuel-feeding equipment were still continuing to perform its task as usual.

LETTERS INTERESTING AND INSTRUCTIVE

Information Wanted on Buggyabouts for So. Africa.

Editor THE AUTOMOBILE:

[788].—As a subscriber and interested reader of your journal, will you kindly tell me which of the vehicles called "buggyabouts" you consider the most practical and reliable machine, irrespective of cost. I am desirous of introducing them into this country, where our roads are not good and many small streams have to be crossed, and where high wheels are a necessity. Do you think the means taken of keeping the cylinders cool sufficient? It is pretty hot here in the summer, about 80 degrees in the shade. I should be glad to hear of the experience of anyone who has tried one. I am alluding to such vehicles as the Holsman, Dayton, and others. G. C. WILLIAMS.

Maritzburg, Natal, South Africa.

Like the "best car" question, on which you have doubtless noted our remarks in a recent issue under this heading, this is a rather difficult question to answer. It is narrowed down to a certain class, it is true, and naturally there is always a *best* in every class, as we ourselves have been at pains to point out, though this does not materially lighten the task of making a proper reply to your query. There are at present a dozen or more of this type of vehicle being turned out to a greater or less extent in this country, and no two are exactly alike, so that the adherent of any particular system, such as two-cycle air-cooled, four-cycle air or water cooled, planetary transmission, chain, friction or rope-drive can find something to suit his fancy. There are many days in summer here when the temperature exceeds the figure you mention, and little or no difficulty is experienced in efficiently cooling such motors as these cars are equipped with. They are designed for strenuous work, such as would naturally be called for in traversing the South African country, and can make good speed on the level. The number of parts is few and they are made as simple as possible, so that we should think that by ordering a number of the parts most likely to go wrong, thus having them ready for replacement at any time, considerable hard service could be obtained from such a car.

However, this does not bring us any nearer to the main point of your question, as to which is the best car of this type. To be frank, we really do not know, for, never having had an opportunity to test them out on the road, we have had no occasion to note their performance in use. We very much fear you will have to decide the matter for yourself, as in every other question of a similar nature; but the publication of your letter will doubtless come to the notice of a number of the makers, who will facilitate matters by presenting their respective claims for preference in the way of advertising literature. If any of our subscribers have had any personal experience with machines of this type we should like to hear from them fully.

An Inquiry Regarding a Separable Differential.

Editor THE AUTOMOBILE:

[789].—Being a subscriber to "The Automobile," I would like to ask you regarding a form of differential that is applied to each wheel, instead of at the center of the rear axle or on the countershaft, as is ordinarily the case. Any information you can give me will be appreciated. W. J. SEITZ.
Monroe, Mich.

The only invention of this class that we can recall was termed the Hedgeland anti-skid axle—that is, the only one that reached the market on any scale in a commercial form. We do not remember exactly the details of its mechanism, but the principle was that of the free wheel used on bicycles, the power being applied on rounding curves to the slower moving of the two wheels, the inner, while the outer was allowed to run free owing to its higher rate of travel. So far as we know at present, this device is no longer on the market and we have no knowledge of any other of this type.

Points of Interest About Magneto Ignition.

Editor THE AUTOMOBILE:

[790].—I have a four-cylinder car of the regulation type which is equipped with two independent ignition systems, one having a set of four unit vibrator coils, timer and accumulators, and the other a self-contained system consisting of a high-tension magneto, on which practically nine-tenths of the running is done. I do most of the work about the car myself, and have become familiar with it. What I would like to have some light shed upon is the radically different action of the magneto ignition as compared with the battery and coil side.

1. That is, why is it possible to advance the spark so very much more in using the magneto to start on without having the engine kick back, as would be the case were the battery current used under the same conditions? In fact, it is necessary to advance the spark control lever quite a distance in order to make it possible to start on the magneto.

2. How do you account for the fact that once under way it is not necessary to shift the magneto ignition except very rarely, also that shifting the lever back and forth a number of notches makes but little perceptible difference in the running of the engine. In other words, it is necessary to shift the lever considerably more to slow the engine down by retarding the spark when running with the magneto than with the battery, and it is seldom if ever necessary to advance it, the engine doing its best at a fixed point with this system.

A little light on these questions would be greatly appreciated by the writer, and probably by a number of others who have observed the same things in the handling of their cars. B. H.

Babylon, New York.

1. To take up the latter part of your question first, a little study of the working of a magneto will readily make clear the reason for advancing the spark much further in order to start the motor. As the armature of the generator is bi-polar, it generates but two impulses per revolution; between these there are neutral or dead points, at which no current is passing. The current wave produced is in the form of a peak, considering the neutral points as being on a horizontal line, as explained some weeks ago in THE AUTOMOBILE. From this line the current wave rises sharply while the poles of the armature are passing the edges of the pole pieces of the field, or cutting the lines of force of the magnetic field, as it is termed technically. The wave reaches its maximum when the center of the pole of the armature corresponds with the diagonally opposite edges of the field pole faces, when it begins to drop as rapidly, crossing the horizontal line and repeating the same operation beneath it. The meeting of each pair of these lines forms a triangle, with the horizontal line as a base; the apices of these triangles are the peaks of the current wave, and only a certain percentage of the latter is available for ignition purposes. This was graphically shown by the illustrations published in connection with the article already referred to. At the top of the peak the current reaches a maximum value; the object is to utilize it as near the latter as possible. Taking 15 per cent. of each side of the peak as the amount available, the duration of the generation of this portion of the current, measured on the arc of a circle representing the revolution of the armature, gives the number of degrees that it is possible to advance or retard the occurrence of the spark. In equipping a car with a magneto the latter is timed so that the greatest amount of running can be done when the generator is giving its maximum spark. But when turning the engine over by hand the generator is at a considerable disadvantage, owing to the extremely low speed at which it is revolved. It cannot produce more than a small fraction of its rated current output and it is not as quick to act, which explains both the reason for the necessity of giving the lever considerably more advance than with the battery, as well as the possibility of doing this without fear of the motor kicking back. In other words, the location of the spark advance lever has considerable influence on the character of the spark produced in the case of the magneto, which is naturally not the case with a battery and coil system, as the latter depends upon a constant source of cur-

rent, the only variation of which lies in its exhaustion or gradual approach thereto when the spark becomes weaker, and considerably more advance is necessary. Apart from this and the fact that improperly adjusted vibrators or other sources of current wastage tend to run the battery down, it is not at all influenced by the same considerations as those mentioned with regard to the magneto. The fact that it is possible to safely start the car with the ignition advanced as well as the fact that it does not require constant shifting are both advantages in its favor.

2. Much of the information requested by your second question has been covered in answer to the first. As already explained, the peak of the current wave represents the maximum current value and, accordingly, the best possible running point for the engine; no amount of shifting one way or the other can improve it. Another very important reason is the fact that the magneto acts *instantaneously*. There is a popular belief that this is true of the electric current under all circumstances, but such is far from being the case. There is quite a perceptible interval between the time the battery current is sent into the primary winding of the induction coil and the moment the spark is produced in the cylinder. This arises from several causes, such as the fact that the core of the coil must be magnetically saturated before it acts, the inertia of the vibrator must be overcome, and the like. The magneto armature is also wound to generate the current at a very much higher potential or voltage than is possible with a battery. The fact that shifting the spark advance lever back and forth on the sector makes little perceptible difference in the running of the motor is due to the excellent current wave produced by your magneto; its value is the same for some distance either side of the peak, which also accounts for the greater distance it is necessary to move it before a retarding action takes place, or before a point is reached where a much weaker part of the current wave produced is being utilized.

Varied Queries About Christie's Grand Prix Racer.

Editor THE AUTOMOBILE:

[791.]—Kindly answer in "The Automobile" these questions: Has the Christie Grand Prix car any front springs? How is it possible that the steering wheels are fully responsive to the steering wheel and still transmit the motive power? How is the connecting rod attached to the front axle? Why is not the two-cycle engine more popular if it gives more even torque than a four-cycle engine? In an emergency how can a car be run without the pump? Which shaft travels the faster, the cam or crank, and how much faster? Bayside, New York.

VINCENT BOELKE.

Walter Christie's Grand Prix racer has coil springs and heavy rubber buffers as front suspension. The front road wheels respond readily to the steering wheel owing to the interposition of a universal joint between each end of the driving shaft and the road wheels. Christie's machine has no front axle; the connecting rod is behind the circular steel crankcase, set across the fore end of the frame and united to the steering arm in the usual way. Steering control, however, is by rack and pinion. Full particulars of the machine will be found in the April 11 issue of THE AUTOMOBILE. Although possessing distinct theoretical advantages, the two-cycle engine, as at present constructed, has certain grave defects. It is not so economical of fuel; it has not the suppleness of a four-cycle engine, and is consequently less suitable for automobile work; there is always a danger of premature ignition if the engine does not clean out the burnt charge sufficiently. On some engines the pump could be disconnected and thermo-siphon water circulation employed temporarily. Owing to the smaller volume of water and the smaller section of the tubes, however, it would only be a makeshift remedy at best, and on many engines would altogether fail to produce a flow of water. The crankshaft travels the faster; ratio on a four-cycle engine is 2 to 1.

TESTING OUT MOTORS AT THE POPE PLANT.

Editor THE AUTOMOBILE:

[792.]—At the present time anything connected with an automobile is a subject of absorbing interest to the average man, and

a visit to an automobile factory which is producing cars in large quantities is a delightful revelation.

Few men who purchase a car fill up the gasoline tank and the oilers and then start off for a tour have any comprehension of the patient care and skill which follows every operation of construction and assemblage from the first conception until the machine is finally handed over to the customer. No matter how carefully or accurately an automobile may be made it cannot do good service and live up to the high standard required by its conscientious maker unless each one of its many parts is properly adjusted so as to work in harmony with all correlating parts.

In order that the manufacturer may be absolutely certain that machines leave his hands in proper condition for immediate use it is necessary to employ a corps of skilled and experienced mechanics, not only for the purpose of testing and trying out each part as it is assembled, but finally to prove up the whole car as a unit.

A brief sketch of the methods employed will undoubtedly be of great interest. Take, for instance, a four-cylinder gasoline engine; while it is comparatively simple in construction it is composed of many parts, and it is absolutely necessary that each one of these parts be made with accuracy and without variation from the accepted standard. The parts are so carefully designed that in a first-class automobile factory the engine when put together in the assembling room goes together without the use of elaborate tools other than the wrenches necessary for fastening and bolting the various parts into place.

In the great Pope plant at Hartford there is one special department devoted exclusively to the testing of engines, and it is a very fascinating sight for the visitor to go into this room and see engine after engine in a long row, fastened each to its own stand and working away smoothly and quietly without seeming effort. When the engine is delivered to the testing room it is securely bolted to an iron stand and is then connected by a belt to the main line shafting and driven for hours by outside power, being fed with oil and other lubricants and continually supplied with water through its circulating system. This work is continued until all the adjustments are accurately made and the engine runs freely and smoothly, without heating, or, in other words, it "finds itself."

When it has passed this test it is then connected with a fuel tank and with its ignition system, and then started and run under its own power in the same manner as it would be in the hands of an owner. This test always takes a number of hours, and the exact and rigid requirements of the Pope factories demand that it shall stand it without a murmur, running with quietness and smoothness and without heating in any of its essential parts. If the engine fails to pass this test it is sent back to the assembler, who takes it to pieces, locates the trouble, and replaces with new parts those which are not running satisfactorily.

Any engine which passes this crucial test is in shape to be assembled into a complete chassis and put through the test of actual use on the road as a part of a complete car. After the automobile is put together and passed by the various inspectors it is turned over to the final testing department, which is composed of men who by their long experience and special training are fitted to adjust and tune up the car to "concert pitch." A set of old tires is put on the wheels and a special testing body is fitted to the chassis and the car is then sent out for practical road adjustment in the hands of an expert.

In the vicinity of Hartford, where the main Pope plant is located, it is an everyday sight to see these cars running in numbers with their rough bodies and mud bespattered wheels over hills and country roads for miles around. It is the testing all along the line which insures a product satisfactory not only to the makers, but to the users. It is practically impossible for a car to pass through all these tests and trials without there being detected any slight lack of adjustment or flaw in the entire construction. When so proved up the car is turned over to the shipping department and the makers feel sure that it will go into the hands of the consumer in perfect condition.

CHARLES E. WALKER,
Vice-President, Pope Mfg. Co.

Hartford, Conn.

MAYBE THERE IS WATER IN THE CYLINDER.

Editor THE AUTOMOBILE:

[793.]—Answer to No. 767. Take off cylinder head and see if water is not leaking into cylinder. This would cause engine to be very hard to start, as a small quantity, say a tablespoonful, of water in cylinder makes it almost impossible to start. Take the gasket off and you can tell from that, as it will look black where the water leaked through. I had a car come to my garage that was in just this fix—everything seemed all right except that it was very hard to start after it had stood idle.

I hope this will help No. 767. I should like to hear from him as to whether this is the trouble.

Corisicana, Texas.

CLARENCE THOMAS (Auto Doctor).

HOW THE NEW PACKARD LOOKS WITH LIMOUSINE BODY.

IN line with its well-established policy of devoting its entire attention to the production of a single model each season, which it has now consistently adhered to for several seasons, the Packard Motor Car Company, Detroit, will pin its faith for the season of 1908 to the Packard "Thirty," which is essentially a continuation of its predecessor of the present generation, barring development in the shape of detailed refinement that has been suggested by experience and observation during the past year. All those basic features of construction and design that have fulfilled the object of their creator by giving satisfactory service on hundreds of cars in daily use all over the country, have been retained intact, forming the groundwork upon which the designer has built up a system that may appropriately be termed "thoroughly Packard" throughout, so long have its principal elements been identified with this car.

Among the chief changes that will serve to distinguish the new car to the experienced eye will be its slightly increased wheel-base and the employment of 36-inch wheels, though the most distinctive marker that will enable the automobile-wise to immediately pick the 1908 model out of a crowd, as it were, consists of the altered design of the radiator cap or filler opening. Realizing the inconvenience of the screw-thread method of fastening such a part, a bayonet form of lock has been adopted for it, and

the same is true of the fuel and lubricating oil-tank caps, thus rendering their removal the work of but a moment.

The rating of the four-cylinder water-cooled motor, from which the car takes its name, is 30-horsepower at the extremely moderate speed of 650 r.p.m., but its dimensions of 5-inch bore by 5½-inch stroke make it apparent that this is merely nominal and that its actual output is far greater. In fact, it is rated according to the French "system," and as the French autoist has to pay an annual tax based upon the horsepower of his car, it is easy to see why horsepower ratings are kept low regardless of motor dimensions, in view of which it is not surprising to learn that the Packard motors have turned up to practically double their nominal rating on the brake. Their French rating grows out of the fact that the cylinder castings, as well as the pistons, piston rings, blank and exhaust manifold castings, are imported from France in the rough, being cast from a gray iron mixture specially adapted for the construction of such parts. The cylinder castings are of the twin type, with oppositely disposed valves of the outboard type, actuated by separate camshafts enclosed in the crankcase. High-carbon open-hearth steel, that is received in the shape of hammer-forged billets, constitutes the material from which the crankshafts are cut. The shafts are oil-tempered, bearing surfaces ground, and the entire shaft machine-

INTAKE SIDE OF PACKARD MOTOR, SHOWING CARBURETER, ETC.

EXHAUST SIDE, SHOWING OIL PUMP, MAGNETO AND TIMER.

finished. The connecting rods are drop-forgings, and both the crankpin bearings and the main bearings are of special Parsons white bronze, the piston pins being carried in hard bronze bearings. Grinding is employed wherever possible to obtain extreme accuracy, such as in the finishing of the inside of the cylinders, the pistons, piston rings and the like, all three being "lapped" with a suitable polishing agent in addition, giving these parts the highly finished surface that is so essential to an absolutely smooth working fit.

The crankcase is cast of a special aluminum alloy in three horizontal sections, the camshaft gears, as well as those of the magneto and the pump, being contained in a separate but integrally cast oil-tight extension of the crankcase. The uppermost section of the latter forms a base for the engine and is supported directly on the side members of the frame. Between the lugs

or transverse supporting arms is cast an integral web entirely enclosing the space between the motor and the frame from beneath, thus affording complete protection to the engine as well as its accessories, and particularly the magneto.

The Packard motor is distinguished from the majority of American motors by other departures from what may best be termed standard practice, owing to the number of instances in which it is followed. Chief among

DIFFERENTIAL AND CHANGE SPEED GEAR.

these is the retention of a governor, of a special hydraulic type, originated by this house and long a feature of its cars, while the other is the use of a water-jacketed carbureter. The latter is of special design and construction throughout. It is of the standard aspirating-nozzle, float-feed type, with an automatic auxiliary air-inlet, and is fitted with a butterfly throttle. The auxiliary air-inlet is of the poppet-valve type, and is controlled by a small helical spring, the tension of the latter being readily adjustable to suit changing atmospheric conditions by means of a sliding wedge actuated from the driver's seat by a small lever on the dashboard. The fuel supply is taken by gravity from a tank under the forward seat, and having a capacity of twenty-one gallons, while the water-jacket circulation is a part of the cooling system of the car. This is also true of the hydraulic governor, which acts on the butterfly throttle. The cooling system consists of a fin tubular radiator supplied by a gear pump and supplemented by a belt-driven fan mounted on annular ball-bearings. But six gallons of water are necessary.

Both the ignition and lubrication systems are of considerable interest, and particularly the latter as being representative of as close an approach to ideal simplicity as can be found in this very important essential of the car. More than that, it has the great advantage of being practically self-contained, thus

SEVERE SIMPLICITY OF THE PACKARD DASHBOARD.

requiring but a minimum of attention for its proper maintenance. It consists of a cylindrical copper tank placed upright between the cylinder units, this location insuring a supply of oil at the proper consistency at all times, despite weather conditions. A double-plunger pump, actuated by a worm on the exhaust camshaft, connects with this tank of oil. There is a transverse central partition in the oil pan of the crankcase to preserve the oil level in climbing or descending grades, and each of these compartments is fed separately by the oil pump. Before passing to the crankcase the oil goes through two sight-feeds on the dash.

High-tension ignition is employed, an Eisemann magneto being used in regular service, while an imported Fulmen set of accumulators is used as a reserve and for starting from the seat. The magneto proper is of the low-tension type, employing a single non-vibrator coil to transform the current, distributing it through the synchronous mechanism on the generator. On the accumulator side a single vibrating coil is used, both these units being placed in a case on the dash, while the timer is mounted on a vertical shaft at the rear of the motor. There is but one set of secondary connections and one set of spark plugs, the distributor of the magneto being employed in the same capacity when the car is being run on the battery, thus greatly simplifying not alone wiring, but also reducing the amount of apparatus needed.

With the exception of the use of a newly designed universal joint of the yoke type, fitted at the clutch end of the propeller shaft, the various steps in the transmission of the power are the same as in former models. The Packard screw-and-nut-actuated internal expanding clutch is retained, as is also the same type of rear-axle unit construction that has long been a distinguishing feature of this car. This is shown complete in one of the accompanying illustrations. The same housing covers gear-set, final drive and differential, and a new design, in which the interior of the casting is ribbed and its outside face smooth, has been adopted.

ELEVATION OF CHASSIS OF THE PACKARD "THIRTY" FOR 1908.

IN addition to being one of the first of the six-cylinder models for 1908, of which full details are forthcoming, the Great Chadwick Six represents an example of automobile construction embodying numerous features that are both out of the ordinary and of interest from a technical as well as a popular point of view. Its title is an apt one, the significance of which is only appreciated upon reviewing the specifications of the car itself, as the latter is one of the largest of its kind ever regularly catalogued either in this country or abroad. Large cars are not uncommon any more than are those of the six-cylinder type, but a six-cylinder car of this size is certainly a rarity, as will be at once apparent when it is stated that the cylinder dimensions are 5 inches bore by 6 inches stroke, while the motor is geared considerably higher than is customary with anything but specially designed racing cars, the motor making but 19-20 turns for every one of the driving wheels. Despite the unusual size of its cylinders, as well as the fact that its compression is reasonably high—in fact, investigation shows that the latter essential is not far from the average, reaching as it does, 70 pounds to the square inch absolute—the motor of the Great Chadwick Six is rated very low, merely being credited with 70 to 75 horsepower. A few years ago such an engine would have been rated at double this, and no doubt it shows a substantial excess over its rating on the brake, particularly as its normal speed is 1,100 r. p. m., which gives the car itself a speed considerably better than a mile a minute without urging the motor in the least.

More than that, the excess of power is such that probably the motor will never be called upon to develop more than 50 per cent. of its rated capacity under anything except extraordinarily bad conditions.

Motor Design.—It will be evident at first glance to those who are familiar with previous Chadwick productions that the same ideas and features of construction that have always characterized the work of this designer have been perpetuated here. The first of these to attract attention is the peculiar cylindrical copper water jackets completely surrounding each of the dual cylinder units as well as their valves. It would seem that this arrangement necessitated the use of a comparatively large quantity of cooling water, but quite the reverse is the case, as only six gallons of water in all are required for this large motor. The idea of the design has been to attain uniform cooling and to achieve this result a much larger mass of water is concentrated around the hottest parts of the cylinder than is usually the case in the great majority of standard American cars. The upper

ends of the valve chambers project through the top of the jacket and are threaded to take spanner nuts which, when set up in place, serve to hold the jacket down against its seat cast on the cylinder. This integral flange fits the inside of the jacket and the latter is retained in place by driving a special steel ring down over the outside; the flange on the cylinder has a liberal face and is given a slight taper, thus facilitating the making of a water-tight joint at this point. The system also dif-

INLET SIDE OF MOTOR OF THE GREAT CHADWICK SIX.

DETAILS OF THE FOUR-BEARING CRANKSHAFT AND THE CAMSHAFTS.

fers from others in that two supply openings are provided, that entering the exhaust side being larger than its opposite near the inlet, both coming up from below. As shown by the illustration of the carbureter side of the motor the water leaves the jackets at their centers through nipples connected with the return pipe to the radiator. A rotary pump driven by a jaw clutch from the end of the magneto shaft, and a belt-driven fan complete the cooling system. The valves are oppositely disposed and are actuated by separate camshafts with integral cams as shown by the illustration, which also depicts the four-bearing crankshaft. Laminated fiber and bronze and steel pinions, completely encased, are employed and make for silent running.

Carburetion and Ignition.—Probably the most distinctive feature of the carbureter is the manner of its control. The throttle lever is connected with a system of linkage by means of which both the amount of mixture permitted to enter the cylinders is not only varied, but likewise the amount of gasoline that enters into the composition of that mixture, and as this is adjustable so as to cause the throttle to open faster or slower than the fuel admission valve opens, an extremely wide range of carbureter effects is easily obtainable. Fuel is admitted at the side of the lower portion of the body of the carbureter which is surmounted by the float of annular form. The spray nozzle is located in the center of the open part of the float and is surrounded by the main air-passage, the auxiliary supply being regulated by the diaphragm shown and entering through a valve at the left, controlled by a small helical spring. A small hole in the center of the top of the diaphragm case admits atmospheric pressure to this side of the diaphragm, its vertical movement being regulated by the speed of the motor and the consequent depression set up on its under side.

The ignition is duplicated throughout, a rather unusual thing being found in the employment of a set of dry cells as the source of starting current, the running all being done on the magneto end of the system which consists of a LaCoste high-tension magneto forming a self-contained unit on one side and a Bosch magneto of the same type on the other. Each magneto is wired to a separate set of spark plugs, the former system also being inter-

SHOWING THE COMBINED DISTANCE ROD AND CHAIN CASE IN PLACE.

connected with a Herz timer and La Coste coil, and using the set of dry cells to start on, so that in reality the car actually has three systems of ignition, two of which are wholly independent, while the third may be used separately in case of emergency, particularly as it is used with a third set of plugs. All the wiring is enclosed in copper tubes.

Transmission System.—This essential of the car is distinguished by the use of a change speed gear set of original design in that the countershaft carries a large double-faced bevel to each side of which the main and lay shafts of the gear-set are respectively engaged. The double bevel is fixed to the differential sleeve. Four speeds forward are provided, but the design is such that the set is unusually compact, only one pair of spur gears being used for each of the three speeds below the high, while the latter is direct. With the exception of the intermediate reversing pinion, which, on account of the slight measure of service demanded of it, is mounted on a bronze bearing situated below the oil-level of the case, the main and lay shafts as well as the countershaft carrying the differential are carried on D. W. F. ball bearings. Both the bevel and the spur pinions are of chrome nickel steel.

The clutch is of the standard conical type, the male member of which is faced with sheet phosphor bronze, riveted on and turned true in place, the female member being formed in the fly-wheel itself. Through this phosphor bronze facing are placed 60 cork inserts 3-4 inch in diameter, the latter being hand-finished in place and projecting very slightly above the metal. The clutch is of a somewhat large diameter—17 1-2 inches—but is very light, which is also true of its single actuating spring. Final drive is by double side chains and the chief feature of this essential of the car is the employment of a very ingenious form of chain case, some idea of which may be gained from the illustration showing it in place. This chain case is combined with the distance rod separating the rear axle and the countershaft, and its construction embodies many novel features. The distance rods are banjo-shaped castings of manganese bronze, the rear axle passing through

THE NEW CHADWICK CARBURETER

the center of the large end, permitting them to swivel about while the forward end accommodating the countershaft is in the shape of a slot to permit adjustment of the latter, this being accomplished by means of a set screw and pinching lock screw which draws the split-end of the bronze casting together. These distance rods also carry the two halves of the aluminum chain case, no provision for telescopic action being necessary in the latter, as the forward part of the case does not move with the chain-adjusting travel. Though very light, the construction is very substantial and is moreover very simple, which permits of its ready removal and replacement when necessary, at the same time providing that thorough protection which adds so much to the efficiency of the chain drive.

Chassis Details.—A channel section frame of chrome nickel steel forms the foundation of the chassis, the motor base lugs being bolted directly to the main frame, while the gear case is suspended between two of the central braces of the main frame, no subframe being employed. The front axle is a one-piece chrome nickel forging with a 4-inch drop, and the rear axle is of similar material and construction. The suspension consists of two 40 by 2 inch semi-elliptic springs forward and platform system in the rear. The wheels, all of which run on two sets of D. W. F. ball bearings, measure 36 by 5 inches and are shod with Continental tires.

A ROUND Brittany, in connection with the tour of Normandy, will require an additional five or seven days, and the two, combined with Touraine, say three weeks, allowing at least a nodding acquaintance with the charms of these three fairest and most picturesque provinces of France.

If Normandy or Touraine be considered separately, and one comes out direct from Paris, there are 250 kilometers of the Route de Bretagne before Mayenne is reached via Alençon, or 300 to Laval via Chartres and Le Mans. It is a superb itinerary by either route, but if one is bound for St. Malo and the Côte d'Emeraud, or Concarneau and its *plages*, there is still the matter of another 300 kilometers to roll off before one arrives at their objective, and one will have no time to linger en route, save to make such passing observations as fancy suggests.

From Paris, then, the best route is out via Versailles, Chartres, Nogent-le-Rotrou and Le Mans, through the very heart of one of the finest agricultural regions in all France, with Routes Nationales all the way, great tree-bordered, sandy-surfaced roads without flints, hidden level-crossings or bad curves, save here and there where one passes through some little old-world village with a cobble-paved main street. It is in these crowded little French towns that most automobile accidents happen; but the local authorities generally cut your *vitesse* down to 12, 10 or 6 kilometers an hour and put up great starting signs reading "*Ralentir*" or "*Virage Difficile*," so it's your own fault if anything happens. What you want to look out for before and after coming to a town are the *culverts* and *canivoux* crossing the road; many a back spring has been broken by taking them at a speed above a dozen miles an hour. Generally they are marked, and so, too, are dangerous cross roads, by the distinctive signs of the A. G. A. (the man who evolved this system of road signs knew the needs of automobilists).

From Le Mans, practically the gateway to Brittany, it is another hundred kilometers to Laval. Coming out of Paris, lunch at Nogent-le-Rotrou, at the Hotel du Dauphin. There is nothing of luxe here—simply plain, bountiful fare, cooked and served by the *patron-chef* of the hotel (*vin compris*), and charged for invariably at the same price, whether you be a peasant-farmer in town for the day

with a donkey cart loaded with vegetables or an automobilist in a flying "fifty," with a tonneau loaded with fair women. This is the charm of French travel by road. It's only in the resorts, like Biarritz, Vichy, Trouville or Aix-les-Bains, that one pays through the nose, as the French say.

Nogent-le-Rotrou is worth an hour after lunch, looking over its three mediæval monuments, its two churches dating from the tenth to the fifteenth century, and its eleventh-century ruined chateau, unspoiled by modern embellishments.

Where You Can Breathe the Atmosphere of the Middle Ages.

It is sixty-seven kilometers to Le Mans and seventy-five more to Laval, where you may sleep at the Hotel de Paris or keep on another thirty-five kilometers to Vitré, by which time the entire topographical aspect of the land has changed and become sterner, with more of the quality artists call character and less of the scenic prettiness of the stage.

Laval is really worth seeing. It is an admirable relic of an old mediæval town, with a twelfth century donjon, a Renaissance chateau, a twelfth century church and a fortified gateway, besides a history made vivid by its seigneurs of the moyen age. Indeed, Laval and its neighbor, Vitré, with an excursion to the Chateau des Rochers of Madame de Sévigné, are taken together, worth a day's sightseeing, if that's what you are out for, and probably it is. Thus keep Laval and Vitré on your route card.

Vitré's chateau is the best photographic subject among all the chateaux of France, save perhaps Langeais in Touraine, therefore don't forget to carry your kodak along with you.

At Vitré the Hotel des Voyageurs, besides the railway station, has good, but small, garage accommodations, and *chambres hygiéniques*, installed at the suggestion of the Touring Club de France. The combination, with the very excellent fare and the extremely moderate charges, will be hard to beat in all Brittany or Normandy. For that reason it is worth making a long day to arrive at Vitré for the night. The excursion to the Chateau des Rochers should not be omitted. It is five kilometers from Vitré, along a beautifully boulevarded roadway, quite different from what it was in the days of Madame de Sé-

"TROT, TROT TO MARKET" ON THE BRITTANY ROADS.

vigné when that accomplished letter-writer informed her daughter, Madame de Grignan, that "finally she had arrived," after having made the last league on foot, leaving her coach stuck among the rocks and mud of a slough.

There is nothing very massive about the chateau, but its ensemble is exceedingly picturesque. One may visit the chapel

HANDY WARNING SIGNS ARE EVER PRESENT.

and the *chambre* occupied by Madame de Sévigné, and may walk in the alleys and be told by the *concierge* that *par ci* and *par là* Madame la Marquise used to take her promenades. A very beautiful garden it is, too, designed by the great Le Notre, who laid out the gardens of Versailles.

Something About the Ancient Capital of Brittany.

If one will, he may go on to Rennes, thirty-five kilometers, the ancient capital of the province, but it's a stuffy, pompous hole with hotels always full to overflowing with congressionists of a medical conference or something of the sort, and automobilists have a scant welcome. The only thing of note to see at Rennes—its cathedral is abominably ugly—is the Council Chamber of the Palais de Justice where the Parlement de Bretagne formerly sat. This is not prejudice, but the writer has got a rule for touring which invariably works well: make your stopping place a small town, not a large city; leaving price out of the question, it's more amusing and the fare is better and more characteristic, and that verily is what one wants, or ought to want, when traveling by automobile.

Cut Rennes out, then, and go north from Vitre to Fougères, twenty-eight kilometers. Merely a sight of Fougères, *en passant*, is worth coming miles for. It is one of the best examples of a decrepit old walled town to be seen in France outside of Carcassonne. It is palpably a ruin, and its walls and towers and crenelated battlements and pinioned chateaux are all inextricably mixed in such a maze of architectural wonders that it looks more like a thing of the imagination than reality. Not many tourists—automobilists or others—"do" Fougères. This is a pity! Anyway pass through it en route for St. Malo, Dinan and Dinard.

From Fougères to Dinan, via Dol, is seventy-eight kilometers and about the same to St. Malo. The former is preferable, as it allows one to make a gorgeous excursion by a little steamer down the Rance to St. Malo and Dinard. It is a trip not to be missed by all lovers of the beautiful.

From Fougères to St. Malo, including the steamer trip, is good for a day. The Hotel de France et Chateaubriand—the ancient home of the author himself—is very good indeed, but a typical tourist hotel where one eats at one of those interminable long-drawn-out tables d'hôte, the curse of all resort hotels.

Sea, Sky and Land Form Color-schemes of Wondrous Beauty.

The historical monuments of St. Malo and its neighbor, St. Servan, their cathedrals, the Chateau, the old fortifications, the Tour Solidor, etc., are wonderfully interesting, and the green sea and blue sky setting of it all is as impressive as anything of its kind in nature or art.

From St. Malo westward to St. Briec is the Côte d'Emeraud, one of the beauty spots of the coast line of France. It is lined with little resorts and detached villas, and the panorama is only comparable with that of the Riviera—the Côte d'Azur and Biarritz, and about there—the Côte d'Argent, with, of course, quite a different color scheme.

From Dinan to Brest, almost to the extremity of Finistère, is something over two hundred kilometers of exceedingly pic-

turesque rising and falling route nationale. Generally speaking, the surface is good—the best in Brittany—but there are many hills of from eight to ten per cent., not so heavy in grade as the cross-country routes, say from Dinan to Vannes or from Morlaix to Quimper, but annoying all the same, for it's a continual coaxing and pushing of one's automobile in order to keep moving without being obliged to change speed.

After Dinan comes Lamballe, St. Briec and Guingamp, all of them typical Breton towns, peopled with a sturdy, dark-skinned folk, who, for a fact, are becoming so used to intercourse with strangers that they have lost not a little of their former picturesqueness. The *chapeau paille* and the *gilet rond* are giving way to an imitation *panama*—made in Madagascar—and a sweater knitted in Nottingham. Farther west in Finistère, and in the Penmarc'h peninsula, the costumes of the peasant men and women are, more or less, as they were a hundred years ago.

A detour of a hundred kilometers might be made from Guingamp, via the coast towns of Plouha, Paimpoul (where most of the women are widows, their menfolk having been mostly lost in the Newfoundland or Iceland fisheries), Tréguier (Rennan's birthplace) and Lannion. Practically this detour will take a day. There is much of interest en route and it's worth going slowly over the ground.

If one leaves Guingamp in the morning—a much better stopping place than St. Briec, it's only half the size, though both are full of quaint houses, curious shops and architectural surprises—he might lunch at Tréguier, spend an hour in the afternoon at Lannion, full of curious old wood and stone houses, or stop en route and have a look over the old Chateau de Tonquédec, ten kilometers distant. This last is a grand old ruin of the fourteenth century, with a donjon with walls ten or a dozen feet thick and all the accessories of a mediæval fortress-chateau.

The road drops down from Lannion in thirty-six kilometers through a wild, savage region with sharp descents to Morlaix, the Sous-Préfecture of Finistère. The Hotel de l'Europe is double starred in the Guide Michelin and the Hotel de Provence bears a single star, but the latter is decidedly preferable. Each has garage accommodation of a very acceptable kind.

Religious Ceremonial Remains Dear to the Sturdy Breton.

There are numerous sights at Morlaix in the town itself, and the excursion to the fourteenth century fortress, built by the bourgeois of Morlaix as a defence against the English, in the Rade de Morlaix, a great land-sheltered bay or harbor, should not be omitted from your visiting list.

Directly north of Morlaix, twenty kilometers out and back, is St. Jean-du-Doigt, a famous place of pilgrimage among the

Breton fisher folk of Finistère and the Côtes-du-Nord. In the church is preserved as a relic the index finger of the right hand of St. John the Baptist. The great religious fête, known as the Pardon of St. Jean-du-Doigt, takes place on the 23d of June in each year, and is perhaps the most celebrated of all these great religious pilgrimages of Brittany.

Northwest of Morlaix is the Pays de Leon and Finistère, a region to be "explored" by any automobilist who likes to get away from the beaten track. The roads are passable, that is, good enough as to surface, when they are not "loose" or broken up, but the hills are practically a continuous performance. It is a region away off from the rest of France, the "Land's End" of North Europe, and no one among its peasant population knows or cares for anything away from his immediate environs. *Essence* and *huile* are hard to find; there are only 110 automobiles registered in all Finistère, and this includes Brest, Morlaix and Quimper, which account for most of them. In the Côtes-du-Nord there are but 70, in Ile et Villaine 144, and in the Morbihan 59, making less than four hundred in all Brittany. No wonder that the native never ceases to marvel at *la mécanique* and marvel still more when you put in the "reverse." If you've got a "cut-out" from your exhaust box he flees in terror, thinking the whole thing is about to blow up. It will be some years yet before "*ces choses droles, ces automobiles*" will fully "arrive" in the wildnesses of Finistère.

Between Morlaix and Brest, Landivisian and Landerneau are interesting, but Brest itself had better be omitted. From Landerneau to Plougastel is a dozen kilometers, and the view over the great Rade de Brest is finer than anything from the other shore. For the night Plougastel-Daoulas is not bad. The Hotel des Voyageurs has been braced up quite recently by the Touring Club de France and is about the most modern thing in the hotel line in these parts outside the large towns.

From Daoulas, fifty or sixty kilometers out and back, will bring one to Crozon and Camaret. If you would like to know what it looks like first there is a picture of "Sardine-boats at Camaret," by Cottet in the Luxembourg Gallery at Paris. There are no sunsets quite so brilliant in western Europe as those over the bay of Camaret. If that interests you the detour is worth making, otherwise one reaches Quimper from Daoulas, via Chateaulin, by route nationale No. 170, in sixty kilometers.

From Quimper there is a hundred kilometers round to Douarnenez, Pont Croix, Pont l'Abbé and Penmarc'h that shows the best of Brittany; the quaintest, the least spoiled and the most picturesque customs and costumes of men and women.

The *coiffes* of the Breton women are the strangest and most varied in France, and those of the women of Penmarc'h, the Bigoudens, the quaintest of all.

Quimper has twenty thousand inhabitants, and if one excepts the great marine arsenal of Brest is the metropolis of Finistère.

From Quimper to Rosporden is twenty-two kilometers by the route nationale, Nantes-Quimper. Rosporden is a sleepy, dull town, with nothing to detain the tourist more than a glance of the eye, but it is the turning point for Concarneau—where the sardines come from.

Concarneau is ancient, picturesque and smelly, but it is delightful all the same, and the sea food served at déjeuner at the Hotel des Voyageurs will be remembered for long. *Langouste rémoulade* and *sardines fraîches* are *plats* which cost relatively large sums of money on the Paris boulevard, but here they are regular *plats du jour* and you pay three francs only (*vin compris*) for your déjeuner or dinner.

Americanism Has Invaded Independent Brittany.

Pont Aven for the night, at the Villa Julia, is the best thing to be had in Brittany. Julia years ago ran a modest little artists' hotel (for Americans, curiously enough), but to-day it has grown with prosperity until there is a great four-story brick and steel structure beside the little inn, and there are electric lights, electric bells and ice water on tap, also whisky—both

kinds—the American kind without an *e* and the Scotch kind with an *e*. Blanche Willis Howard's story of "Guenn" will tell you much of the life of the peasant folk of Pont Aven and ought to be read *on the spot* to be thoroughly appreciated.

There are fourteen water mills at Pont Aven and it is locally known as the *Ville des Moulins*. When we do the same thing in America we nickname a place Millerstown and let it go at that. As Laurence Stern said, "They do things better in France."

(To be concluded.)

BRITAIN'S USE OF FIRE BRIGADE AUTOS.

LONDON, June 11.—Automobiles for fire brigade service have found great favor in Britain and their use has been extended to the majority of the large cities. The latest convert to mechanical traction is the Birmingham Central Brigade, which has just taken over the smart vehicle illustrated. Made by the Wolseley Com-

BIRMINGHAM'S "FIRE-LADDIES" ABOARD THEIR AUTO HOSE CART.

pany, at their neighboring works, the chassis has a 30-horse-power four-cylinder engine located beneath the driver's seat but readily accessible by removal of the floorboards. Two ignitions are provided to minimize risk of stoppage, this and the other constructional details following the standard omnibus practice of this firm. Four speeds are provided and side chains take the drive to the rear wheels. As the wagon is intended for city work a big maximum speed is not provided, twenty miles an hour being normal with full load. The body accommodates sixteen men and a supply of hose-piping and accessories beneath the seats. The preliminary trials have served to indicate that this vehicle will do good service at a cost much below that of the horse-drawn hose wagons.

A JOURNALISTIC WILD FLIGHT OF FANCY.

"Quite the most original device for protection against flying particles of sand, mud, and even stones, of which the racing automobilist is so much in need, was used by Fabry in the recent Targa Florio contest. His steering wheel, which was slightly larger than usual, was backed with mica, and constituted an excellent protection against the wind and dust, as will be seen by an examination of the accompanying illustration."

It is a New York automobile weekly which is responsible for the transformation of Fabry's steering wheel as described above. Unfortunately for the weekly's accuracy, Fabry's steering wheel was of the ordinary garden variety, as devoid of mica as the wheels of his car. *English Motor*, in one of its weekly facetious sketches, depicted Fabry behind an exaggerated wheel and suggested that it be enlarged still more, mica inserted so as to form a combined steering wheel and wind shield. A Parisian journalist, whose English was probably of the elementary school stage, mistook the London artist's wild fancy for a reality. The New York editor, apparently, must have missed the original and "borrowed" the idea from the French publication.

Rise of a New National Institution.

From the small beginnings of the event inaugurated by the New York Motor Club a few years ago there bids fair to develop an annual observance of national importance—a national charity, in fact—Orphan's Day. The seed planted by the local organization has been fostered by the good offices of the American Automobile Association, and with the latter's aid its benefits were made far reaching, June 12 being observed as National Orphans' Day for the first time this year.

It would seem that there could be no greater charity open to the autoist than to devote his car for a few hours to the enjoyment of as many homeless waifs as it will carry; but, sad to relate, the private owner has not shown any great amount of enthusiasm in making this benefaction. Barring a few clubs, which for reasons of local convenience celebrated some other day, June 12 was observed as Orphans' Day in a number of cities, but it was the men who make and sell automobiles that supplied most of the conveyances. In other words, it was a trade event, rather than the public charity that was intended, and the number of cars fell far short of that required. It is sincerely to be hoped that next year a more generous response will be forthcoming to the appeal on behalf of this most worthy of charities.

Present Status of the Air-cooled Motor.

Certain developments of the past season have led a goodly portion of the automobile public to jump to sudden and wholly unwarranted conclusions regarding what may best be termed the air-cooled situation. Briefly put, these certain developments were nothing more or less than a sudden cessation of interest in the

subject on the part of two or three makers, their defection being signalized by bringing out a water-cooled car.

Many have been unable to see anything in this other than that the air-cooled motor had been tried and found wanting. More than one maker had put it to the test and then abandoned it. Nothing could be further from the actual state of affairs. The air-cooled motor long since reached a stage where it needed no defenders. By every test known to the engineer, it has been tried and not found wanting; many of the earlier fallacies concerning it have been brushed away, and in a hundred ways the air-cooled motor has been proved to be all that has been claimed for it, and a little more. But every buyer of a car is not an engineer—the public is not alone not discriminating in mechanical matters, but it is possessed of a tremendous amount of inertia. As a result, the manufacturer of air-cooled cars has been compelled to do a great deal of missionary work, and selling an air-cooled car to a new buyer means making a convert.

With the exception of those few makers who have developed highly specialized systems of air-cooling which are exclusive with them, and who in consequence have numerous special features of construction on their cars, the process of proselyting has been found expensive and burdensome. While the fact that as with steam, once well-converted means faithful to the end, is a great advantage, the work of constantly making new converts is one that the maker without a large and well-organized selling department has found constituted a task in which the game was not worth the candle. In some cases it was not alone necessary to make the convert, but keep him firm in his faith, as he was prone to ascribe other defections to the fact that the car was air-cooled. It soon became apparent that three water-cooled cars could be sold with less effort than it took to dispose of one of the other type where there were no special features to recommend it. Anyone who is conversant with trade conditions in this country is well aware that the average maker is quite willing at all times to give the public what it wants. He is in business to make cars, but he has to sell them, and in the long run he is going to make the car that sells the easiest.

Influence of the Auto on Machine-Tool Design.

From the manufacturer's point of view, there is little doubt but that the most revolutionary improvement brought about by the automobile has been in machine tools. It has been the cause of inaugurating new shop methods, but far more has it been responsible for the transformation of the shop equipment. The first automobiles were built of the most available and cheapest materials. But a very brief period of use was required to show their inadequacy for the purpose. Makers were willing to pay the cost, even though it were many times greater than what had been considered good enough for other purposes. Insistence and an open purchasing account finally won the day.

Then he found himself confronted by a totally new and unexpected problem. He now had the materials, but no machinery to work them with. To quote one of the most prominent makers in the country: "We found it a hopeless task to attempt to turn a piece of alloy steel in one of our old, small lathes. The machine chattered and jumped, threatening to go to pieces every minute. In the course of about two years we scrapped practically every tool we had in the shop and replaced it with new and heavy equipment at many times the cost, though the old machines were still good for several years' service on ordinary work." This is but a single instance of many. Practically every maker in the country has had the same experience, and its mark is visible in every department of machine tool equipment and shop practice. Such machinery represents a large outlay, so that in making it the automobile manufacturer has not blindly reproduced on a larger scale, but has introduced improved methods and processes. As in steel making, machine tool design has advanced more under the influence of the automobile than it would have in several times as many years otherwise.

SEALED BONNET CONTEST IS ON.

"Mollycoddle procession" was the playful title the Automobile Club of America's Sealed Bonnet Contest had earned for itself before the finish of the first half day, for the time allowance was so liberal, roads considered, that the schedule was a crawl all the way. But thus far it has proved one of the most successful contests ever held. Fine roads and beautiful weather contributed their share, while the cars did their work nobly. Every one of the 47 starters turned up promptly on time at Patchogue, and by 7:30 P.M. practically every one of them had made an equally consistent performance of the slow run back and had either already been checked in at the clubhouse or was waiting its turn at the elevators. S. B. Stevens' 16-20-horsepower runabout, carrying No. 46-A, was the last to start, and consequently finished latest through a strict observance of the spirit of the contest rules. He reached the clubhouse at 9:41, his maximum time being 9:53:00. There was a remarkably small amount of tire trouble all told. The De Luxe rolled in on a flat rear tire, of which its occupants were blissfully ignorant until someone at the club asked if the car ran better that way, but it was about the only one of the 47 to finish that reported anything of the kind, the Darracq evidently getting far more than its share in this respect. The 35-horsepower Oldsmobile runabout driven by W. Folberth and carrying 27-B was the first to check in on the return at 5:27, followed by the three Locomobile touring cars at 5:30 and after that they came so thick and fast that 54th street was blocked and the clubhouse checkers rushed to death. The Haynes runabout with C. B. Warren at the wheel, that took honors in its class in the recent mudlark tourney to Albany, was a prominent early arrival, while the Mora runabout 32 B, driven by W. H. Birdsall, had the distinction of having done the distance on five gallons of gasoline.

As of old, of course, not a few of the contestants declined to be bound by such limitations on the way out to Patchogue from Newtown and "let her out some" to preserve tradition in such affairs, and not let the custom of racing for controls die too easily. As a result the sleepy little Long Island town on the south shore received its first notice of the advent of the contestants by the arrival of a pair that trooped in about half past eleven. These were the De Luxe 24-A driven by C. S. Beach, with the Glide, 4-B, driven by J. C. McCafferty, at its rear wheel, and they had maintained that position all the way out, so that the occupants of the latter car were considerably heavier than when they had started by the addition of a liberal coating of Long Island realty.

Then there was a lull of almost half an hour while the first arrivals formed centers of interest for the local gentry who gathered to inquire what it was all about. Shortly after midday they were supplemented by scattering pairs and single arrivals that soon swelled the procession, and as the cars ran about a mile or so east of the town to check in at the official turn and came back to "stoke up and lubricate," the quiet main street took on an air of animation. It was dusty, very dusty, but that there was no necessity whatever for piling it on one another was amply demonstrated by the trip back. If there has ever been another more orderly "take it easy" procession than the one that characterized the return trip on Wednesday afternoon, no one who has followed American automobile contests ever since there have been such things can remember.

Before starting out in the big De Luxe that brought us back, times and distances were figured to the minute and we rolled along in an easy-going fashion that brought a stare of surprise from other autoists who sped by on the road, going at what is an ordinary pace for the automobile. Ours was "fifteen per," by the autometer, but it seemed more like five, and just to be able to kill a little more time the photographer was given plenty of opportunity to press the button on a number of charming scenes that the eastern end of the south road affords.

HOW THE GRAPHIC CUP WAS WON.

DOUGLAS, ISLE OF MAN, June 8.—The touring car race for the Graphic Cup has just completed the programme of the Manx meeting. Any powered touring cars costing less than \$5,000 are eligible under the rules of this annual competition.

Hutton's 60-horsepower Berliet got away first and managed to do fastest time in three minutes and forty seconds, equivalent to forty-five miles an hour. The 40-horsepower Berliet, owned by Watson, took second place, with three minutes, forty-five seconds, and a similar car driven by Porapato, who, together with Hutton, drove a Berliet in the Tourist Trophy race, was placed sixth.

The event was not without its excitement, for after yesterday's adverse weather the roads were in the worst possible condition. All the cars found some difficulty in keeping on the road, and unluckily No. 13, a 45-horsepower Ariel, smashed up at the corner which had already claimed the Napier and Daimler as victims. The occupants of the car were thrown out and serious injury resulted to one unfortunate. A 35-horsepower Daimler which was running well broke a chain near the finish, otherwise Daimlers might have done better than take third place. No American car was entered, but several automobilists on tour attended.

POPE MANAGERS HOLD THEIR ANNUAL DINNER.

HARTFORD, CONN., June 17.—On Thursday of last week the Pope managers and their assistants "got together"—that is, they had their annual round-up meeting in Hartford to talk over business plans, and taking a run later in two Pope-Hartford and two Pope-Toledo touring cars to Middletown, where they became the guests of Albert L. Pope, Vice-President of the Pope Manufacturing Company, at dinner. From Toledo came A. E. Schaaf and Harold L. Pope, manager and assistant manager of the Toledo plant, as well as F. C. Gilert, the sales manager. Manager H. H. Rice and his assistant, W. C. Johnson, came from Indianapolis; Robert E. Beck reported from Hagerstown, and E. Hinsman, general manager of the Westfield factory, was in evidence, as was also M. V. Kelley, a publicity man of Toledo, who handles a large share of the Pope interests. Colonel Albert A. Pope came early and staid all day. At the dinner there were in addition to the above, Colonel George Pope, Charles E. Walker, W. C. Walker, Robert L. Winckley and C. E. Morrow, all of the Hartford plant; C. E. Lozier, manager of the Elyria factory, and M. L. Lawrence, superintendent of the Hagerstown plant.

FIFTEEN FRENCH 'BUSES FOR FIFTH AVENUE.

PARIS, June 13.—New York has come to Paris for a supply of motor 'buses for its aristocratic Fifth Avenue, L. K. Clark, of the New York Transportation Company, having placed an order with the Motor Car Emporium, Limited, of London, for fifteen De Dion Bouton gasoline omnibuses similar to the two hundred at present in use in the British capital. Although manufactured at Suresnes, near Paris, this type of 'bus is better known to Londoners than to Parisians, owing to the more general adoption of this form of locomotion in London than in Paris. Numbers of them, however, are in use in France on long journeys between a series of villages, where the railroad has not yet penetrated. It is expected that the 'buses, which have seating accommodation for thirty-four passengers and are similar in body work to the one now being used experimentally on Fifth avenue, will be in active operation by the end of July.

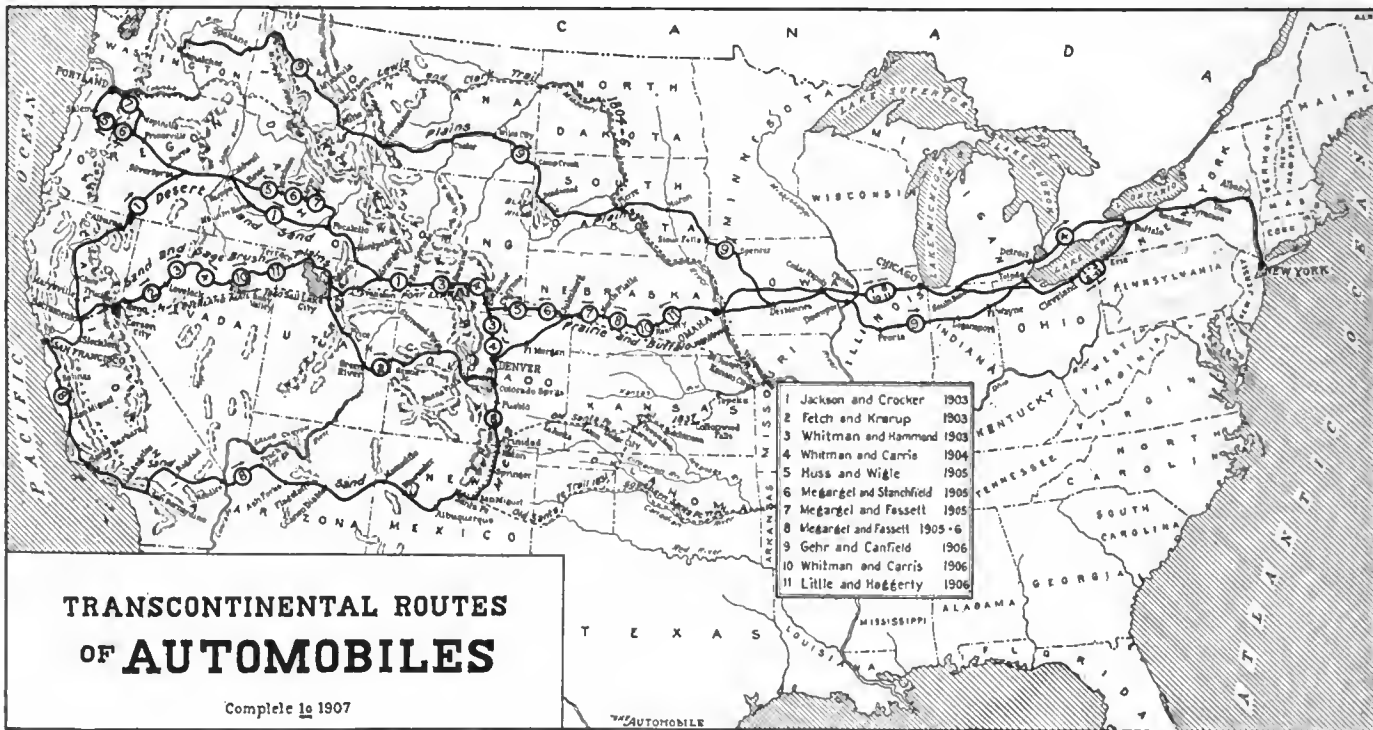

EDITOR BATCHELDER NOW A BENEDICK.

Wednesday morning, June 12, Amos Grant Batchelder, managing editor of THE AUTOMOBILE, was married to Mrs. Lottie De Wolfe Bates, of Boston, at the Harvard Congregational Church, Brookline, Mass., the Rev. Oliver D. Sewell officiating. The wedding was private, only a few intimate friends of the bride being in attendance. Mr. and Mrs. Batchelder are now enjoying a brief honeymoon in the Adirondacks. Their numerous friends unite in extending congratulations and best wishes.

TRANSCONTINENTAL FEATURE OF THE BLUE BOOK

THOUGH road information on an extended scale is practically a new departure in this country, great progress has been made in these lines during the last two or three years. For the first time it is possible for automobile tourists to secure reliable information that will enable them to plan trips from any point on the Atlantic seaboard—from Calais, Me., to Norfolk, Va., inclusive—into and through the Middle West by the most practicable routes, with good accommodations practically all the way.

edition, and with it appear tables showing the date of start, date of finish, time, place of start, place of finish, names of drivers, make and principal specifications of cars making each one of these trips, including the three transcontinental motorcycle trips between the Atlantic and the Pacific. Nearly everyone of these long trips has been made in a strenuous fashion, with record-breaking part of the original plan, as the tables themselves show. It will be noticed that all of these long runs followed practically

From the Official Automobile Blue Book, slightly reduced in size.

The three volumes of the 1907 "Official Automobile Blue Book" contain descriptions and maps covering in the aggregate about 50,000 miles. While this is only a small proportion of the total mileage of highways, it contains by far the best routes threading the entire territory.

The engraving shows one special feature of the 1907 "Blue Book" that has never been attempted before—a summary of the eleven transcontinental trips that have been made up to the present time. This drawing, somewhat larger than the accompanying map, is one of the supplementary features to the New York State

the same course from New York to the Missouri river, but from that point west they diverge into four general routes. This was due principally to the place of start or destination of the different trips, and not to any special difference in the road conditions, as there is no good highway between the Missouri and the Pacific ocean. To add to the interest of the diagram as a whole the overland mail route—Pony Express—and the old Santa Fé trail have been charted out, showing how the automobile has used in part the pioneer routes of the mail and commerce across the plains and the mountains.

EARLY SUMMER ACTIVITIES OF THE CLUBS

Rochester to Hold Its Auto Gymkhana on June 29.

ROCHESTER, N. Y., June 17.—Owing to the fact that many automobilists will be out of the city for the Fourth and will not return for several days thereafter, the gymkhana sports of the Rochester Automobile Club, which were to be held at Genesee Valley Park July 6, will be held at that place on June 29. Invitations have been sent to the members of the Buffalo Automobile Club to come and compete, and the contests will be open to all owners of cars in Rochester, whether they are members of the local club or not.

There will be eleven events: a half-mile speed contest; 100-yard dash, standing start, the front wheels to cross line and then reverse 50 feet; 100-yard dash with one front wheel running along a hundred feet of narrow wooden pathway; obstacle race; tilting at rings; dropping stones or balls into buckets along a 100-yard course while driving at the rate of 15 miles an hour; brake contest; balancing contest; potato race; needle threading contest, open to electric cars only and to have women passengers; riding for scarfs.

All entries must report to the secretary fifteen minutes before the opening of the first contest. Not less than three prizes will be offered in each event, and it has been planned to have these peculiarly suitable to automobile owners. The committee in charge of the sports is composed of H. T. Strong, chairman; H. S. Woodward, William Barry, Jr., J. S. Bingham, A. F. Crittenden, F. E. Mason and Rudolph Schmidt.

The Rochester Automobile Club is planning a return invitation to the Rochester Yacht Club, which promises to be quite an event. Plans are also being made for a great automobile day for Rochester. The road sign work starts this week and there has been low rate automobile insurance secured. The chauffeurs' registration bureau is started and the membership is growing every day. Arrangements have also been made by the club by which any member wishing to visit or tour Canada by communicating with Secretary Van Tuyle have all the bother and trouble in regard to bonding machine, putting up bond, etc., taken care of without any trouble to themselves.

Chicago Automobile Clubhouse Opening Is in Sight.

CHICAGO, June 17.—Fearful lest the pranks of the conscienceless weather bureau or the dilatory tactics of an unsympathetic contractor may cause another upset of their plans, the directors of the Chicago Automobile Club are delaying positive announcement of a date of the housewarming in the new Plymouth Place structure. It is positively certain, however, that within three weeks' time the club's new home will be occupied. On the evening when the doors are first flung wide the members of the club will make their acquaintance with the interior of the structure, which is expected to serve not only as the headquarters for automobilists of Chicago but for the entire Mississippi Valley district. A few evenings later the first ladies' night will probably be observed. As the labor of the builders has approached an end the full scope of the architects' plans have become manifest and high praise is being accorded them for the attractive decorative effects secured throughout the building.

On the garage floors all work was completed some days ago, but it was decided not to open the garage for storage of cars before the entire building was ready for occupancy. In the culinary department, which is located chiefly on the third floor, every effort is being directed toward completing the installation of fixtures in good season for the opening.

The Chicago Automobile Club is distributing a 24-page booklet containing the new automobile law of Illinois, which goes into effect July 1. The work is of vestpocket size, appropriately indexed, and contains a number of explanatory notes by Sidney S. Gorham, the club's efficient secretary and legal adviser.

Revising the Rules for the Quaker City 24-Hour Race.

PHILADELPHIA, June 17.—The committee having charge of the coming 24-hour race of the Quaker City Motor Club, on the 28th and 29th of this month, is determined that no possible chance for a protest shall be afforded, such as marked the conclusion of the similar event held at Point Breeze track some weeks ago. Second place was jeopardized in that event by the Frayer-Miller crew pushing the car over the tape after the car had been laid up for repairs. A set of rules governing the running of the race has been promulgated, and the one covering this point reads as follows: "Contesting cars must be running under their own power at the conclusion of the race to receive an award of position."

Wholesale rebuilding of a wrecked car, such as followed the smash-up of one of the contesting Dragons in the last race when it somersaulted through the rail, is aimed at in the following paragraph: "Each contesting car will be allowed five mechanics for replacements." It will be recalled that fully a score of men were put at work on the Dragon and had it in shape for going again in less than two hours. But for some such rule a local manufacturing concern would have a marked advantage over a firm which has possibly sent its car hundreds of miles to enter the race, and with but half a dozen or few men to attend to it.

Another rule prohibits the filling of fuel tanks or the making of even minor repairs on the track. Any such replenishments or repairs must be done in the respective camps, which will all be located in the infield, the parking spaces, which are usually located there, being relegated entirely to the outside.

Additional lighting facilities will be installed, and reflectors will be used to throw the rays ahead and keep the glare out of the drivers' eyes.

The field, if anything, will be larger than in the last event. Two new cars which will start will be the Loziers, entered by Harry Michener and Ralph Mulford, of New York.

Perfect Score Contestants Refer Cup Back to Trustees.

NEWARK, N. J., June 17.—It was hoped last week to narrow the field of contestants in the recent New Jersey endurance run who finished with a perfect score, by a 24-hour non-stop contest, but all plans of that nature were set at naught by the action of the race committee, which, after a meeting, called the owners of the twelve perfect score cars together again on Thursday and refused to accept the plan which had been suggested for disposing of the cup, thus reopening the whole matter. After considerable discussion the contestants decided to leave the matter with the committee with the recommendation that the cup be left in the custody of the trustees of the club with power to act. The committee endorsed this recommendation, and now the question of the disposal of the cup is simply transferred from the race committee to the board of trustees.

There is much talk now of whether or not the club officials will consider it advisable to make the endurance contest an annual fixture. Several contestants voiced the opinion Thursday night that no contest could be arranged on the roads of New Jersey which would be within the limits of the law, and yet in which several of the competing machines could not finish with perfect scores, and cited the repeated and futile attempts of the committee handling the Long Island endurance contest to narrow the competitors down to one clean score. A contest in which medals or certificates should be given to all who competed without penalization was favored.

Grand Rapids Club Plans a Run to Detroit.

GRAND RAPIDS, MICH., June 17.—The touring committee of the automobile club is making arrangements for a run to Detroit to compete for a silver cup offered by President George of the State

association. The date has not yet been set, but the committee plans to bring off the event soon.

Agitation has started in the city hall to keep the autos from the parks this summer. The idea is that the dust raised by the autos injures plants and flowers, endangers the lives of children, and is in general a nuisance. These, however, are the ideas of the extremists, and when it comes to carrying them out it is not thought they will have any support. The club itself is in favor of speed regulation, but the members feel that they have as much right to the parks as anybody.

City and Country M. C. Will Celebrate July 4.

NEW YORK, June 18.—The City and Country Motor Club has announced a jollification for Independence Day. The glorious Fourth will be celebrated by a big run to the Lake Mahopac Club-house and an outing during the day on the lake and grounds. In the afternoon there will be a promenade concert by the Thirteenth Regiment band, and there will be athletic games and water sports on the lawn and lake. In the evening there will be special fireworks and a lawn fête, with moving pictures and other entertainments. Arrangements have been made for additional ac-

LAKE MAHOPAC CLUB HOUSE, OF C. AND C. M. C.

commodations in nearby houses for the overflow from the clubhouse of those who wish to remain over night at the Lake Mahopac headquarters. The run will be from the 109th street city clubhouse early in the morning.

Albany Club's Seven Day Tour Starts To-day.

ALBANY, N. Y., June 20.—A score or more strong, the third annual tour of the Albany Automobile Club left the capital city to-day with horns tooting and the occupants of the cars in the gayest of moods. The tour is to be of seven days' duration and will cover a total distance of 660 miles, the route taking the tourists to Atlantic City via Asbury Park, N. J., and returning via Trenton.

MR. HOLLANDER MAKES A BUSINESS CHANGE.

E. Rand Hollander, who is one of the best known members of the auto import trade in this country, last Saturday resigned his office as vice-president of the Hol-Tan Company, of New York City, importers of Fiat cars, thereby severing his connection with that concern. He sailed on Thursday for Europe to conclude negotiations for one of the largest international automobile deals yet put through.

Though Mr. Hollander declined to state anything regarding his plans, it is understood that a syndicate has been formed for the manufacture in this country of a famous foreign car, and that he is going abroad to sign the contracts for the purpose.

AMERICAN CARS IN IRISH RELIABILITY TRIALS.

DUBLIN, June 7.—While the Royal Automobile Club busies itself with fuel limit races and formula-handicapped hill climbs, the important task of organizing reliability trials has devolved on the sister associations of Ireland and Scotland. The annual trials starting from Dublin and from Glasgow rank as two of the principal competitive events of the year and the organizers have the pleasure of seeing the entry lists mount up without trouble to the limit of efficient management.

In the main section of this present event the Irish Automobile Club received fifty-one entries, which were grouped in seven classes on a price basis. A further section was provided for members and private owners, and some twenty-one cars ran under this heading. America was represented by six vehicles, a 32-horsepower Maxwell being piloted by its owner in the private section, and two Cadillacs, two 15-horsepower Fords and a six-cylinder Ford running in the main body.

The weighing in caused much amusement by the serious determination of the clerk of the scales to portion out the necessary sand ballast to the nearest ones, and this conscientious spirit was shown throughout by the observers—rumor alleging that one driver got into trouble for winding up the dashboard watch. The four days' run commenced on Wednesday morning with a trip north to Portrush, one hundred and fifty miles of mixed roads which proved a pleasant surprise in view of their anticipated roughness. The sixty-eight cars which turned up were sent off at minute intervals, but for some reason the order of starting placed the higher powered cars last, rendering a great deal of passing necessary before the close of the day's run. Fifty-nine non-stops were recorded for this day and the remainder all managed to report before the close of schedule time.

Thursday's course led back to Dublin by the inland road through Armagh, a run of 173 miles, sufficiently long when the legal twenty mile and hour limit has to be followed. After passing through Coleraine the procession headed for the nine-mile stretch of beach locally styled Magilligan's Strand. A plank track marked out a safe course over the soft sand and the fine surface soon reached well repaired the trouble.

In the below \$1,200 class the 10-horsepower Adams-Hewitt did best with a speed of 34 1-2 miles an hour, the 15-horsepower Ford coming next with 33 and the Cadillac two-seater with 30 miles per hour. Below \$1,750 the 16-20-horsepower Calthorpe averaged 42 miles an hour, 8 miles an hour above the next best.

After the speed event the road to Armagh was resumed, but elimination soon commenced, ten in all being absent at the end of the day's run. The majority of these withdrawals were occasioned by the stringent rule disqualifying any car which experienced a stop of longer than one hour.

Waterford was the objective of the third day's run, which included a timed hill climb at Hollywood Hill, over a mile of 1 inch 12 average gradient. The Ford and Cadillac again did well in their class, taking second and third places. The route lay through some of the finest of Irish scenery, but the good weather suddenly failed at lunch time and mist and drizzle were the main features of the trip to Waterford. Fifty-five arrivals reported themselves to headquarters, forty-seven having no trouble.

On the Saturday return to Dublin a timed ascent of Graiguenamanah Hill enlivened the proceedings. The Cadillac took top place in Class B, with the four-cylinder Ford a close second.

Fifty-three cars completed the 569 mile trial, and altogether 34 made entire non-stop runs. In the B Class none of the eight cars were successful in running through with a clean sheet, and so the Cadillac with its two non-stop and the Ford with three to its credit have good chance of award. On the other hand, in Class F, in which the six-cylinder 40-horsepower Ford was placed, all thirteen made complete nonstop performances with the exception of the Spyker, which had experienced no delay till its damaged axle caused its retirement on the last day. The results and final placings will not be known for some weeks, both cost and fuel consumption as well as reliability and the timed tests being considered by the committee.

LOCOMOBILE INSTRUCTION BOOK FOR 1907 CARS.

In preparing an instruction book for the maintenance of its 1907 cars in the hands of the private owners, the makers of the Locomobile have left no stone unturned to render this handy little volume as exhaustive as it is possible to make such a work without going into abstruse technicalities, that frighten the average man at first glance and cause him to lose all interest in the attempt to master its contents, simply because he does not understand the matter and will not be bothered to learn it. It is divided into eighteen chapters, covering every essential of the car, treating them in the order of their importance to the beginner, such as "Lubrication," "Cranking the Motor," "Changing Gears," and the like, then taking up constructional details and the care needed in their maintenance in later chapters, twenty-seven easily understood drawings being used to supplement the text and render it clear. Every possible phase of taking care of the car is treated at length and in such a manner as not to puzzle the veriest tyro, with an additional chapter or two as an appendix for experienced drivers and repair men, though, as a matter of fact, there is a great deal contained in the body of the work that it would benefit this gentry to read and digest. It is safe to say that no Locomobile owner who will take the trouble to "know his little book" thoroughly will encounter much in the shape of breakdowns that will stump him. For convenience in carrying it is sent out by the makers—the Locomobile Company of America, Bridgeport, Conn.—in a neat leather pocket case, which also provides accommodations for other papers. The purchaser's name is stamped on the inner fold in gilt letters.

BUICK AND JANNEY COMPANIES CONSOLIDATE.

FLINT, Mich., June 17.—The new Janney Motor Company, which has been in process of organization for some time past, was consolidated with the Buick Motor Company last Monday. While losing its individuality in the merger, the Janney cars will bear this name and will be turned out in a separate plant at Flint, where there was talk of locating the factory even before the consolidation. At the same meeting, held last Monday, an increase from \$1,500,000 to \$2,600,000 capital was voted at a special session of the stockholders of the Buick Motor Company. This only concerns the common, the preferred stock remaining at \$600,000. A special meeting of the stockholders of the Whiting Motor Car Company has been called for to-morrow at Jackson, Mich., to vote on the project of also combining with the Buick Company. In any event the plant will remain at Jackson.

The Buick factory at this place is progressing rapidly, the contract for the main building calling for its completion by August 1. This building is 756 feet long by 70 feet wide and two stories high, making it one of the largest of its kind in the country.

EXECUTIVE HEADS OF THE POPE-TOLEDO PLANT.

General Manager Albert E. Schaaf is at the wheel. Assistant Manager Harold Pope occupies the seat at his left. In the middle seat in the rear is F. C. Gilbert, Sales Manager. the others being members of the sales department.

TOLEDO HAS A NEW AUTO PARTS INDUSTRY.

TOLEDO, Ohio, June 17.—Toledo is to have a new automobile industry in the Toledo Auto Parts Manufacturing Company, which has been incorporated with \$50,000 capital and which has already begun installing machinery in the old plant of the Kirk Bicycle Company. The concern is headed by W. N. Taylor, for nearly three years general superintendent of the Toledo plant of the Pope Motor Car Company. Others interested in the concern are C. F. Cook, manager of the Globe Machine Company, G. Ohlinger, T. B. Earl and D. White. It is the intention of the company to manufacture all sorts of automobile parts, as well as rebuild and repair automobiles. The company will occupy the old De Luxe factory.

CONTINENTALS ON FIRST HERKOMER SEVEN.

Tires have spelt defeat more often in a great road race than any other single factor—in fact, the cars themselves have been brought to a point where victory or defeat is almost entirely a matter of the tires used, and the use of tires that cannot stand the pace invariably means a poor showing. In view of this, the report by cable recently received by the New York office of the Continental Tire Company, that the winner of the Herkomer Tour, Edgar Ladenburg, drove a Mercedes shod with Continentals, and that the next six cars to finish also had the same tires is certainly a matter of congratulation. In addition, the first, second and third cars to finish in the Forsten-Rieder Park Race and the first three to finish in the Kesselburg hill climb were all equipped with Continentals.

THE ADCRAFT CLUB, DETROIT'S FAMOUS ADVERTISING MEN'S ORGANIZATION, ENJOYING A RUN IN FORD SIXES.

NOVEL FEATURES OF THE K-W MAGNETO.

Under the title of the "K-W Ignitor," a firm of the same name—the K-W Ignition Company, Whitney Block, Cleveland, Ohio—is marketing a novel form of inductor generator that embodies a number of original features. Both electrically and mechanically it has been reduced to that ideal simplicity which makes for enduring reliability, an essential of paramount im-

EXTERIOR VIEW OF MAGNETO. FIBER-ENCLOSED STRIP WINDING.

portance in all ignition apparatus. A permanent field consisting of four powerful horseshoe magnets constitutes the electrical foundation of the machine, while the inductor consists of two laminated iron rotors placed at right angles and keyed on the shaft. Between them is placed the stationary strip copper winding in its fiber housing, so that there are no moving contacts and nothing to wear but the main bearings, which are of substantial size, which is also true of the shaft, so that with the necessary lubrication the machine will run indefinitely without attention. A view of the complete machine is shown above.

The makers claim for this magneto that, on account of its generating line waves, the neutral point of the machine represents

such a very small portion of the arc of rotation that there is no necessity for synchronizing it with the motor to which it is attached.

To insure this the magneto is arranged to run four times the speed of the motor, or eight times faster than the timer, thus minimizing the angular period of no current. Extensive trial,

as well as a number of machines in daily use, variously run by friction, belt and gearing, demonstrate that

any difference in operation resulting from synchronized attachment and loose driving is a negligible quantity. It is not designed to operate as a self-contained unit, but simply to act as a source of current supply for the usual vibrator coil equipment in lieu of a battery. The wiring connections are the same, and, as the machine generates a powerful current at an extremely low speed, no batteries are needed for starting. The magneto shaft is carried on high-duty ball-bearings running in grease, so that oiling is not necessary more than once a season. Cockcroft & Ballou, 122 West Thirty-fourth street, New York City, are Eastern and foreign distributors for these magnetos.

VIEW FROM BENEATH, SHOWING ROTOR.

HART-KRAFT COMPANY STARTS ITS PLANT.

YORK, PA., June 17.—Ground was broken to-day for the plant of the Hart-Kraft Motor Company, a new corporation which was recently organized in this city. The plant with equipment will cost approximately \$50,000, half of which will be for equipment. The building will be four stories, of brick construction, with a frontage of 115 feet and depth of 64 feet, in the principal manufacturing district of the city.

The capacity of the plant when in full operation will be three cars a day. The company intends to make a specialty of two kinds of cars, a delivery car with a capacity of 700 or 800 pounds and a runabout, both of which will be sold at \$850. The officers of the new company are: L. M. Hartman, president; R. H. Shindal, vice-president; Granville Hartman, treasurer; Donald H. Yost, secretary; Jonathan Jessop, John W. Hartley and John H. Hartman, are other members of the board of directors.

FINE PERFORMANCE OF MIDGLEY TREADS.

In the recent twenty-four-hour race at the Point Breeze track, Philadelphia, the Autocar that carried off the victory was equipped with Midgley tread tires that had already been run a matter of 3,000 miles before going on the track, in spite of which they finished the 791 miles of grinding round the circle track with no other trouble than two punctures. With the aid of the Midgley detachable rim, these were repaired in 2:10 and 1:50 respectively, and the car was again in the running.

After a short time in running on the road the upper side of the four steel piano wire coils that are embedded in the tread wear off, leaving thousands of inverted staples sticking through to grip the road. The Pope-Hartford that recently won the Mexican road race was also equipped with the Midgley treads, and Herbert Lytle has specified them for his Vanderbilt cup car.

A NEW RUNABOUT SIX FROM YORK STATE

W. Mason Turner, who has been identified with the business of selling automobiles ever since 1898 and who for the past year and a half has been sales manager of the American Locomotive Company's New York office, has recently been elected president and general manager of the Colt Runabout Company, of Yonkers, N. Y. As suggested by the title of the concern, its object is to place a line of runabouts on the market, known as the Colt and equipped with a six-cylinder motor. The power plants are to be supplied by the Howard Motor Works of the same city, W. S. Howard being well known as the former chief engineer of the Gas Engine and Power Company. Some idea of the lines of the new runabout may be obtained from the illustration of the latest newcomer in this field at the head of the column. It is a fast and business-like appearing car and is designed with ample clearance and a low center of gravity.

COLT SIX-CYLINDER RUNABOUT—THE LATEST COMER.

No rumble seat is intended to be used, the short space back of the seats being designed to accommodate a 20-gallon gasoline tank, beside tools, spares and tires. A detachable mechanic's seat is carried and when in use is fastened to the left hand running board. The wheelbase is 105 inches and the wheels measure 34 by 4 inches all round.

BRIEF ITEMS OF NEWS AND TRADE MISCELLANY

A. Elliot Ranney & Co., New York agents for the Elmore, have sold 38 cars of this make so far this season, from which it would appear that the three-cylinder motor is still an important factor.

Wichita, Kans., has been selected by the Solid Axle Automobile Company, of Toneka, that state, as the location for its new factory. The company is capitalized at \$200,000. L. K. Mannis is president, and O. H. Osborne general manager.

Requests for literature descriptive of Columbia cars from abroad would seem to indicate that the American automobile is becoming widely known in foreign countries, particularly as many of these inquiries received by the Electric Vehicle Company come from very distant places.

"Like father, like son," is a saying that applies to automobiling as well as other things, as witness the fact that Commodore H. C. Roome, the well-known autoist and yachtsman of Miami, Fla., has presented the Lozier which he drove all last year to his son and has invested in a 1907 40-horsepower model of the same make.

When leaving for the other side with his Grand Prix racer, Walter Christie took with him three sets of Diamond tires, which he will use in the race on his own make of removable rims. He has used Diamond tires in his previous races, but this year has adopted larger sizes, employing 34 by 4½ on the driving wheels and 34x4 rear.

Among the six-cylinder cars to participate in the Glidden tour will be the Rolls-Royce touring car of S. B. Stevens. Mr. Stevens at first intended to drive his runabout of the same make, but later changed his mind and will compete with the touring model as a member of the New York Motor Club, of which organization he is the president.

The Harrison Wagon Works, Grand Rapids, Mich., has decided to dispense with its automobile manufacturing department. Superintendent William A. Hatcher and G. A. Anthony have been authorized by the trustees to dispose of the autos in stock and in process of construction and the machinery, all of which is inventoried at \$182,000.

The Monarch Motor Car Company, Chicago, whose plant recently suffered a disastrous fire, has acquired a tract of fifteen acres at Chicago Heights, and will at once begin the erection of new factory buildings. The main structure will be 350x500 feet, of brick, steel and concrete construction, with saw-tooth roof, and steel frames will be used for the windows.

Another of the factories to be forehanded with its 1908 product is the Aerocar plant at Detroit, which has had one of its 1908 model runabouts on the road for the past month or so. This car was sent to New York and immediately found a buyer; so great, in fact, has the demand for Aerocars become, that the enlargement of the factory would not await leisurely plans, but had of necessity to be rushed.

In a letter dated May 28 at Genoa, Georges Dunoy, who is outlining the

route of the Gold Cup Tour is very enthusiastic in praise of his Stearns car, dwelling particularly on the ease with which it took the worst of the grades in France, Belgium and Italy. He has been so pleased with its ability that he has taken every opportunity to show automobile agents in the various towns he has stopped at just what the car can do.

In a Thomas Speedway Flyer—a duplicate of the car recently purchased by W. K. Vanderbilt, Jr., E. C. Richard and George M. Davis left Buffalo last week with the intention of going round the Glidden Tour circuit in six to seven days. Their primary object is to make a careful inspection of the roads, and on their return a report will be made of the surfacing of the different roads.

E. Linn Mathewson's successful attempt on the 50-mile track record at Denver, when he reduced it to 55:43 4-5, is the culmination of a long line of struggles to lower this mark by drivers of Thomas cars, A. Stanley Zell, of Baltimore, starting it at 1:06:36, Ollie Savin bringing it to 1:06:19 at Chicago, which stood until Ernest Kelly took off a good three minutes at Philadelphia, which left it at 1:03:19¾, all the trials being made in Thomas Flyers.

The Bellefield Motor Company has been formed by J. H. McClaren, George D. Kelley and Frank P. Blackmore. Mr. McClaren is well known in Pittsburg automobile circles, having been the originator of the auto bus line which operated in and around the city for over a year. He is interested in several important automobile inventions and with his associates will engage in a manufacturing business in Pittsburg.

In reports from Europe of touring arrivals at prominent points reached by tourists, the number of American cars is noticeably on the increase. The George N. Pierce Company of Buffalo has decided to extend its system of cars by the establishment in Paris, France, of a department for the supplying of parts, and Mr. N. S. Goodsill, 11 Rue Scribe, Paris, will look after this department. This radical departure will aid Pierce tourists materially.

In securing the Seventh Regiment armory at Chicago for the exhibit of commercial cars during the next Chicago show, Manager Samuel A. Miles has added 30,000 square feet of exhibiting space. Although the commercial vehicle exhibit will be run coincident with Chicago's eighth annual show, it will be known as the first annual exhibition of commercial cars, for the purpose of establishing its identity as a distinct feature of the industry.

On the same day that the New York Motor Club was holding its gruelling endurance run up the state, with Berliet cars doing press duty, another of the American Locomotive Company's products was being put to an equally severe test. This was James Rascover's Berliet, which he drove over Storm King mountain, opposite West Point, with six passengers besides the driver. The roads could not have been worse, but the car did admirably despite its heavy load.

As a result of the great amount of work that has been devoted to it, the

information bureau of the American Automobile Association is replete with data concerning routes for tours in this country, while a membership in the organization is even more valuable to those autoists who contemplate touring abroad. The A. A. A. credentials not only serve as an introduction at the clubs in Great Britain and on the Continent, but also enable one to obtain information concerning foreign routes.

When last heard from, Frank Miller, president of the Bridgeport Automobile Club, was still grinding out miles in his 24-horsepower Premier touring car in the attempt to break the non-stop road record, which he tackled on June 3. He has been jogging back and forth between Bridgeport and New York, averaging a little better than 200 miles a day despite the rough and muddy roads, a little variety being had by taking side trips into the hills, besides going round a circuit over the rolling country back of Bridgeport. In eight days' running Mr. Miller had covered 1,877 miles.

The Dragon Automobile Company, of Philadelphia, has been building some high-powered motors in addition to those designed for its Vanderbilt cup cars, and two of them have been purchased by E. O. Spillman the engine builder, of North Tonawanda, N. Y., who intends to install them in a 12-meter launch now building. The motors are to be coupled tandem and will develop 250 horsepower. The new boat will be named the *Dragon* and is a copy of *Niagara III* so far as the hull is concerned. The latter cleaned up everything on the lakes last year, so that the performance of her new rival will be watched with interest.

RECENT BUSINESS CHANGES.

Apperson Bros.' Automobile Company has removed its salesroom and office from Fifty-second street and Broadway to Fifty-fourth street, just west of Broadway.

H. A. Heinel Company's gasoline engine manufacturers, Wilmington, Del., has sold its business to Jones & Schumacher of that city. For the present the new firm is located at 1100A West street.

Charles R. Johnson, former manager of the Buick-Johnson Automobile Company Grand Rapids, Mich., has sold his interest to George Waller, who has taken the active management. Mr. Johnson will engage in the lumber trade in northern Wisconsin.

The Rambler Garage Company has succeeded the C. G. Norton Company at Milwaukee, Wis., as representative of Thos. B. Jeffery & Company in that city. The present quarters on Broadway will be enlarged by the addition of another story. The officers of the new company are: Charles T. Jeffery, president; Harold W. Jeffery, vice-president and treasurer; O. C. Hutchinson, secretary; A. W. Shattuck, resident manager.

J. E. Demar, the well-known importer of English Daimler cars, has resigned his connection with that vehicle and organized the J. E. Demar Company for

the manufacture of automobile specialties, with a factory occupying over 8,000 square feet at 244 to 250 West Forty-ninth street, New York. The new company will make tops, slip covers, etc., and has been appointed sole metropolitan selling agents for the Crescent detachable rim.

Announcement was made last week that the Willyoung Appliance Company of Yonkers had absorbed the business of the G. J. Schultz Company, makers of Diamond spark plugs. These plugs have been successfully marketed for a number of years and are credited with the biggest order ever given in the spark plug line, being fitted in all Ford runabouts. Elmer G. Willvoug, president of the Willyoung Appliance Company, says the factory is now exceptionally busy.

NEW AGENCIES ESTABLISHED.

Ralph Hamlin, Los Angeles, Cal., has taken the agency for the Lozier in that territory.

The Hartford Auto Exchange, 39 Imlay street, Hartford, Conn., has secured the agency for the Berkshire line.

New showrooms have been opened at 2128 Broadway, between Seventy-fourth and Seventy-fifth streets, by the Auto Improvement Company, of 316 Hudson street, manufacturers of the "Ever Ready" speedometers, tire tools, vulcanizers, etc.

Sales Manager George K. Wheeler of the Columbus Buggy Company, Columbus, O., has established a very important agency for the Columbus Electrics with the Autocar Sales Company, Broadway and Eightieth streets, New York City. The new agents are well fitted for the work, Manager John Milliken having had ten years of electric vehicle experience.

W. D. Newerf, Pacific Coast representative of the Goodyear Rubber Company, with headquarters at Los Angeles, Cal., will establish a branch house in San Francisco on Golden Gate avenue. A. C. Leonard, of Los Angeles, will have charge of the new branch. The Oregon Motor Car Company of Portland has taken the Goodyear agency for that territory and A. G. Emmons, at Fresno, Cal., will handle that portion of the State.

The Winton Motor Carriage Company has established its own branch house in Seattle Wash., at 715 East Pine street, where commodious quarters have been secured. Winton interests in the Northwest have been growing so rapidly as to demand closer attention than could be given otherwise than through a branch house. George W. Miller, formerly manager of the Broadway Automobile Company, of Seattle, is in charge. The Winton Company now has nine branch houses in this country and London.

PERSONAL TRADE MENTION.

Leon M. Bradley of Boston, well known in automobile journalistic circles, will hereafter be identified with the American Motor Car Manufacturers' Association.

L. I. Ollier, who has been manager for the Chicago branch of R. M. Owen & Company, has resigned and gone to Los Angeles, Cal., where he will open a manufacturers' agency.

C. A. Benjamin, vice-president and general manager of the Aerocar Company of Detroit, has been spending a week in the Eastern cities, visiting the principal Aerocar agencies.

A. F. Eckstein, who has been connected with the Thomas B. Jeffery Company at Kenosha, Wis., has joined the forces of the Milwaukee Motor Supply Company, Milwaukee, Wis.

President E. H. Parkhurst of the Peerless Motor Car Company, who has been on an Eastern trip to New York and other business centers, has returned to the factory at Cleveland.

Fay L. Faurote, the well-known publicity manager of the Olds Motor Works, Lansing, Mich., was married Wednesday, June 12, at St. Louis to Miss Emily Ethel Bacon, daughter of Mr. and Mrs. Frederick H. Bacon of that city. The honeymoon is now being enjoyed by the happy pair by a trip via automobile through the Eastern States.

GOOD SALESMEN DESIRED.

The Michelin Tire Company, whose factory at Milltown, N. J., is being prepared for a big output for the coming season, is organizing its sales department and it is reported has a few vacancies for good men.

BOWSER ASKS INJUNCTION.

Charging unfair methods of competition, suit has been filed in the United States district court at Cincinnati by S. F. Bowser & Co. against the National Oil Pump and Tank Company, of Dayton. The action is supplementary to a suit for infringement of patent which the Fort Wayne firm filed against the Dayton concern some months ago. The argument on the preliminary injunction asked for by plaintiff will be heard on June 28.

ANOTHER ROBERTS PATENT.

Letters patent No. 854,709 have just been granted to Joseph Abrahamson, of the Robert Instrument Company, 50 Shelby street, Detroit, Mich., covering improvements in electrical measuring instruments, and specifically in the small pocket volt and ammeters for battery-testing purposes, with the manufacture of which this company has long been identified. The exterior and interior of the instrument broadly covered by the patent are shown in the accompanying illustrations, while the principal points of the invention protected by the patent are included in Claim I of the latter, which reads as follows:

"I—In an electrical measuring instrument, the combination with the casing, its slotted dial and scale thereon, of a coil in the casing forming part of a conductor adapted to convey the current to be measured through the coil, said coil being flattened on opposite sides and formed of a ribbon like conductor of large capacity the individual turns of which are separated by air spaces, a shaft pivoted in the flattened sides of the coil, an armature and a balanced index hand upon the shaft and a permanent magnet secured upon the coil and co-operating with the armature."

INFORMATION FOR AUTO USERS.

Darmac Commutators.—No system of ignition is stronger than its weakest part, say the makers of the Darmac ball-

bearing contact timers, the Darmac Commutator Company, 220-222 East Fifth street, St. Paul, Minn., and the otherwise perfect system is made worthless by the non-dependable timer. To obtain a full spark of exact duration, at the same relative time in each cylinder, and to have the timing under exact control means the maximum power for the

SECTIONAL VIEW DARMAC COMMUTATOR.

motor. This is accomplished by the Darmac timer or distributor because it will not miss a contact at any speed and it cannot vary its timing, all points being rigid as to position and the ball-bearing contact—reduces friction to a minimum. It is built entirely of tool steel and special friction fiber, with special provision to prevent disalignment, so that it will wear indefinitely, the slight embedding of the ball points in the fiber disc as the result of service only tending to increase its efficiency, as a greater section of the ball face then comes in contact with the segment. In other words, like the classic socks, "the longer they wear the better they get." The accompanying illustration, showing a timer in section, is practically self-explanatory. D represents the stationary fiber disc; A the spindle; B the revolving fiber block carrying the tool-steel contact; C F the contacts, and B the balls. The timers are made for all types of motors, from single to six-cylinder, and both plain and with distributors.

A New Tire Saver.—The makers of the Hercules leather tires, the Republican Tire & Shoe Company, 449 West 53d street, New York, have just inaugurated a new process for retreading old and worn tires and by which the old shoes may be ready for service again by the addition of one-piece red or white treads in the course of 24 hours. These treads are quite thick in the center, tapering at the edges, and are claimed to wear much better than the ordinary repair, at half the price. Each tread is fully guaranteed, and both the rubber and leather non-skid treads are covered by patents. Their low first cost and great durability are strong recommendations.

Crescent Removable Rims.—Hot weather and the job of changing a huge shoe on a dusty road in order to mend a puncture, form a combination that the average would rather sidestep every time and how much more the amateur? The removable rim has proven its worth in racing, but has been somewhat slower in achieving recognition at the hands of the tourist. The Crescent rim, formerly known as the Harburg, made by the Crescent Parts Company, of New York City, has a record of 3 minutes for a complete change and is receiving deserved recognition at the hands of the trade.

THE AUTOMOBILE

IF some enterprising jewelry house had sent a salesman to the Contest Committee of the Automobile Club of America any time after last Thursday night there is little doubt but what he would have been given the glad hand, to put it in the vernacular. Wednesday had been a clean-score day for every one of the forty-seven contestants in the club's sealed bonnet contest and Thursday had destroyed the chances of so very few that it looked as if the club would have to go into the wholesale jewelry business in order to supply the demand for the promised cups, but Chairman Morrell said that the prizes would be forthcoming even if it were necessary to put a second mortgage on the clubhouse.

Of the forty-eight entrants but one failed to start, Percy Owen's Bianchi, which was to have been driven by G. Combet; unfortunately, the car had been sold and the purchaser wished immediate delivery, otherwise there would have been a full field. The arrangements were perfect and all the cars were sent away

promptly within a few minutes after 8 A. M. Wednesday, and they were as promptly dispatched by the official starter at Newtown. True to tradition, the run started off as a race and, with the exception of a few of the more conservative drivers who outlined the schedule right from the start and stuck to it consistently, it was a case of get there as fast as you can and the devil take the hindmost, which meant a diet of dust for the whole seventy-five miles. There was quite a different story to tell on the way back, for those who had made up time in the morning had to lose it in the afternoon or be penalized for arriving too early. I rode in the De Luxe and we had things figured down so fine that even the photographer's time was recorded.

This practically tells the story of the first day's run; the cars dawdled so on the last lap of the run that they weren't going fast enough to kick up any dust. It made the farmers take notice to see automobiles going so slowly, and other drivers along the

road were at a loss to make out what kind of a slow race the contest might be. At the end of the first day's run it looked as if the club was in for cups pretty heavily, for the only contestant who failed to report early was S. B. Stevens with his 20-horsepower Darracq runabout, and as tire troubles were his only misfortune he was not disqualified. The first day's run was only a sort of introduction, the route for the second installment of 150 miles having been selected more with a view to trying the powers of the cars, as there is a choice collection of hills between here and Danbury, Conn., by way of Kensico, Bedford and the other towns on that line. But the cars simply ate them up alive, to impress the Coney Island barker's yell; the 45-horsepower Pierce with J. S. Williams at the wheel, in which I rode the second day, making light of even the worst ones on the high, and that in spite of the fact that they are such twisters as to give little opportunity of rushing them. Despite the severe nature of the second day's run the result at the end of 300 miles must certainly have been a large surprise for the committee, the Columbia 45-horsepower gasoline-electric touring car, driven by C. F. Barrett, being retired with a broken valve spring. B. F. Dawson's Stoddard-Dayton runabout, driven by R. Howard, also lost its number through the necessity of putting a nut on the steering gear, which as a matter of fact had simply been overlooked and should have been there before the car started out.

It looked for a time as if others would fall by the wayside, through no fault of their own, however. Considerable pains had been taken in studying the route, and men with green flags were posted wherever there was any opportunity of being trapped by the over-zealous constable. But those at Newcastle Corners thought they ought to have some of the money in spite of this, and they roped in three cars willy-nilly. These were the Maxwell and Mora touring cars, driven by F. Offenhauser and W. Stiekney, respectively, and the Mora runabout, with F. Cimiotti at the wheel. There was a warm pow-wow, and Stiekney took advantage of the opportunity to let in his elutch and slide off, much to the chagrin of the upholders of the law. The J. P., right at hand, said "ten dollars" in the case of the other two, but Mr. Cimiotti protested so strenuously, backing up his argument by the observer's time book, that the heart of the court was softened and remitted the ten. The Maxwell driver was not so fortunate and had to pay under protest. Recognizing the circumstances the committee let it be known that these cars would not be disqualified under the rules to that effect. This left forty-five of the original forty-seven still in the running on Thursday night though the Pope-Toledo, driven by Joe Judge, was protested owing to having used pliers on its accelerator pedal. Thursday was a bad day for the Glide, driven by J. C. McCafferty, who not only had tire troubles, but also broke a detachable rim about twenty miles this side of Danbury and lost two hours while waiting for a new one, in spite of which he turned up on schedule time.

Friday was another easy day for practically all the cars and made the committee open its eyes a little wider, as the 150-mile run which brought the total to 450 miles only served to eliminate one competitor through a most trivial defect. This was the De Luxe touring car, driven by C. S. Beach; when only fifteen miles out a primary short-circuit ended the car's chances, though it continued and even served the next day without mishap as a press car, completing its services by towing in the Welch. The third day's run was along the shore road to Westhaven, just outside of New Haven, the running time being taken from Central Bridge. The first car to report at the clubhouse Friday night was the Locomobile, driven by J. Florida, carrying the number 9-B, which by that time had become quite familiar to all contestants, as the driver with the state name was always met well on his way back long before the end of the line had reached the turning point. How closely the cars simulated clockwork in their movements is evident from the way they reported at this, the end of the third day's run, completing 450 miles. Florida's Locomobile reported at 4:48, followed by W. Folberth's Oldsmobile at 4:59, with the Stoddard-Dayton tour-

TRIUMPHANT RETURN OF THIRD DAY'S RUN.

LUNCH ACCOMMODATIONS.

A STOP ON SHORE-ROAD, THIRD DAY'S RUN.

ing car one minute later; then came another Locomobile with T. Beck at the wheel. After that they came too fast to count, and all except the Glide, which had again been held up by tire trouble, came in as close to the schedule as if they had been limited railroad trains.

This left forty-three cars running as well as ever to compete against the chance of some minor ailment under their bonnets on the last 150 miles of the 600. The Glide accounted for the missing one, having been compelled to raise its bonnet to make repairs to a broken wire. It was hardly thought possible that the Long Island run would serve to cut the list down any. I took this day's run in the big Matheson, handled by Frank Lescault. The Matheson went like clock-work and Lescault kept the speedometer hand glued to the 18-mile mark, except when it was necessary to accelerate a bit to get over a rise on the high or when he got tired of taking all the dust of the man ahead. Beach, who drove the De Luxe, Williams, of the Pierce forces, and Lescault in the Matheson were models of propriety in driving; certainly not even the most zealous upholder of an arbitrary speed limit could find any fault with their traveling, though we were held up in the big Pierce on Friday by one of the city's bicycle cops on the Pelham parkway.

He graciously let us off, however, on the ground that the Pierce was carrying a 14-A; if it had been 13 it would have been all off.

On the way back the story was about the same. The others figured out their times to a dot, so as to bring them in within a minute or two of the minimum. And each one started off on his own hook when it best suited his convenience, so that it was seldom that more than one or two cars were to be seen together at any point along the road. We were one

of the exceptions, the Deere runabout, driven by A. F. Camacho, having broken its speedometer gear and sticking to us as a pilot, as the finishing times of the two cars were but two minutes apart. The performance of the Deere runabout was considerable of a surprise, as it was known to be an old car that had been given no special overhauling preparatory to entering the run. The Welch was also an old car, and the fact that it lasted to within a few miles of the finish of the last day's run was little short of a marvel. It finally came to grief on Roslyn Hill, when three-fourths of the way up, and it is an open question whether it was really the driver's fault and whether the car would really have been able to cross the finish line a winner had a little more foresight been exercised in providing for replenishing the oil supply of the gear case. As it was, its performance was certainly most creditable, and no one who saw it the first day so much as counted it in the running at all where finishing was concerned. Beach in the De Luxe played the good Samaritan and handed out a tow line.

The only other competitor to fall by the wayside on this, the last day of the run, was S. B. Stevens in his 20-horsepower Darracq runabout, which came to grief with a broken camshaft, thus making the average number of eliminations one and a fraction per day for the four days of the run, while the sum total of the troubles encountered was almost a negligible quantity, omitting one or two exceptions. This left forty-one cars to roll home promptly within the eight-hour schedule and forty-one of those expensive cups for the Automobile Club of America to purchase and have suitably engraved with the record of this most consistent of endurance tests that has ever been held.

BRIDGEPORT, WHERE MANY STOPPED FOR LUNCH THE THIRD DAY.

WEST HAVEN, THE TURNING POINT OF THE THIRD DAY'S RUN.

ITALY ALL-VICTORIOUS IN GERMAN RACE

HOMBURG, GERMANY, June 16.—Thursday, under a drizzling rain which transformed the serpentine mountain course into a nerve-racking track, two series of races were run off to decide the starters for the trophy offered by the German Emperor. On the first round there were thirty-nine starters, and on the second thirty-eight, the first twenty of each qualifying for the final. Germany, the most strongly represented, had fourteen cars qualified and nineteen eliminated; France had eight in and eight out; Italy qualified with nine and lost four; Belgium's proportion was six and two; England retained one car and lost two; Austria lost both her representatives, and Switzerland retained the only two Martinis she had entered. The feature of the day was the victory of the Fiat team, the position of the day's result being Nazzaro, Lancia, Wagner, first, second and third, only 6 minutes 35 seconds separating Wagner from his companion, Nazzaro.

At a very early stage the contest settled down to a struggle between Italy, Belgium and Germany. France, with her eight cars, was not a formidable competitor; Darracq had the disad-

had been well sustained, increased to high tension. Lancia, who since his slow first round had been going faster and faster, was first to finish, covering the fourth round in the record-breaking time of 1:21:52, equal to 54.1 miles an hour. Wild bursts, however, will not win modern automobile races, and Lancia had to go down six degrees in the general classification. Deplus, the dangerous Pipe driver, had to abandon on the last round, when second or third position seemed certain, as the result of an accident to steering gear. A tire burst on Hautvast's Pipe when near the end of the race. His Continental-Vinet dismountables soon provided a substitute, and the most remarkable run of the day was finished in good form, the difference between Hautvast's fastest and slowest round being but 2 minutes 22 seconds.

Hardly had the Belgian reached the grand stand than Nazzaro went by with a roar and snatched a glorious victory from his rival by a margin of less than five minutes. As he got out of his seat Nazzaro, with a broad smile over his countenance, declared: "I was never so hard pressed in my life. It was a fine race.

FOURNIER, WHO HAS RETURNED TO RACING.

HAUTVAST, THE TERRIBLE BELGIAN.

SCENE AT ONE OF THE TIRE STATIONS.

vantage of being in the hands of amateur drivers; Lorraine-Dietrich, from whom much was expected, developed a number of minor troubles, and the others were lacking in speed. England was entirely out of the game.

Fritz Opel, who started second on an Opel machine, finished first in a wild rush, followed by Hemery, now in the employ of Benz, of Germany. Lancia, who according to his starting position should have finished early, was slow in coming round, occupying 1:40 to cover the course, compared with 1:23:50, the record established by Nazzaro, and thus losing all chance of capturing the cup. Duray and his Dietrich abandoned on the initial round; Vincenzo Florio withdrew his Darracq with a cracked cylinder; Wilhelm was killed through his Metallurgique overturning at the foot of a descent, and Willy Poegge, with the bad luck which followed him in the Herkomer tour, had to retire with his Mercedes after a dangerous fire at the carbureter.

By the third round the race had settled down to a keen struggle between the Fiat and the Pipe teams, representing Italy and Belgium, with Opel hanging dangerously near. At the end of the second round Hautvast and Deplus, both on Pipe machines, had got a lead on Nazzaro and were running with such remarkable regularity that, barring accidents, victory seemed assured. Hautvast, who had started out with 1:24:14 for the first round, gained 12 seconds on his second round and lost 9 seconds on the third. It was this loss of time on the third round which gave Nazzaro a chance to get ahead. His position, however, was by no means secure, for the terrible Belgian was only 33 seconds behind and his comrade, Deplus, was in a good position and going well.

When the fourth and last round commenced excitement, which

My machine went splendidly, but Hautvast is a terrible driver."

Joerns, on an Opel, who since the end of the first round had been in third place, finished in that position, with his companion, Michel, fourth at an interval of ten minutes. Wagner, who on the second round had lost ten minutes, went faster as he neared the end of the race, finishing fifth, less than two minutes ahead of Lancia. Henry Fournier, riding after an absence of several years from the race track, achieved a notable victory for his Italas from Italy by capturing eighth position. Cagno and Fabry, his team mates, also finished the race, thus sharing with Fiat the honor of being the only team of three to stand the terrible strain.

Emperor William, who from start to finish had not missed the smallest detail of the race, clad in his gorgeous uniform, with fitting royal dignity, presented the cup to Nazzaro and heartily congratulated him on his success.

NEW DARRACQ RACER RESEMBLES VANDERBILT VICTOR.

CANDIDATES FOR GRAND PRIX.

Tuesday next, July 2, on a triangular circuit near Dieppe, the Automobile Club of France will conduct a speed contest which by reason of the fast course selected, the power of the machines and the elaborate nature of the organization, will be the most important of all the races ever held in Europe or elsewhere. Additional interest attaches to the Grand Prix by reason of the application for the first time of a limited fuel supply as the only power-restrictive measure.

Contrary to what might be expected, there are no radical differences between the leading machines of Grand Prix 1906 under the thousand kilos weight limit and Grand Prix 1907 with no other restriction than an engine which does not consume more than a gallon of gasoline per 9.4 miles.

Renault, victorious last year, presents three machines which might at first glance be mistaken for those which Szisz, Edmond and Richez handled on the Sarthe circuit. They are a few inches shorter, are slightly narrower and have profited by the minor carbureter, magneto and radiator changes of touring models.

Brasier, who last year had the honor of being the only French maker to finish with a complete team, has also stuck to well-tried models. Same motor, same wheel base and same track. The radiator is set still further back, being now distinctly rear of the front axle, thus bringing the weight nearer to the hack wheels and assuring the best utilization of the tractive effort. Final drive is by side chain on two and by cardan shaft on one machine, compared with all three chain-driven racers last year. Henri Brasier has probably made more comparative tests with chain and shaft drive than any man living. The tank, tire brackets and seats are as close up to the rear axle as possible, the seats indeed being formed into the tank. A feature of the tire carrying equipment is a strong metal pan large enough to hold three inflated tires. Changes have been made in the carbureter on account of the new racing conditions.

SEATS AND RADIATOR POSITION DISTINGUISH BRASIER.

Darracq is another French constructor who has adhered to last year's types, the racers being practically the same machines as were seen on the Sarthe circuit and in the Vanderbilt Cup contest. Engineer Ribeyrolles has made a change in the clutch, by substituting bronze for leather. The bronze is riveted on the aluminum of the male cone exactly as if it were leather, then turned and ground to fit the female cone. A few grooves are provided in order to allow foreign matter to escape. At the start the clutch will probably slip a little, but will soon give a perfect hold. An advantage is a much smaller diameter. Panhard, on the other hand, has made a complete change, not only in general appearance but in structural detail, as has already been described in earlier numbers of *THE AUTOMOBILE*.

Lorraine-Dietrich racers are shorter in wheel base and are rather narrower, have chain drive, as last year, and have had the engine stroke increased from 160 to 170 millimeters.

Motobloc and Corre, two French firms having had little or no previous experience in road racing, present three and one flyers respectively. The feature of Motobloc is that the motor, clutch and gears are united on one crankcase, forming a single unit or block, hence the name. The four cylinders are cast in pairs, and have 165 mm. bore by 140 mm. stroke. The flywheel is carried between the two groups of cylinders.

Corre, after building small runabouts ever since automobiles were known, experiments with a powerful racer this year. It

CORRE, WHICH WILL MAKE ITS DEBUT ON JULY 2.

has a four-cylinder engine, 6 by 6 inches bore and stroke, developing 90 horsepower. Leather cone clutch, three speeds and reverse through sliding gear, with final drive through bevel gears and rear live axle are its transmission features.

With the exception of the Porthos, to be driven by Striker, a naturalized American, all French machines have four cylinders, there being a strong feeling among native constructors that a multiplicity of cylinders does not tend to fuel economy. The Porthos Grand Prix has eight cylinders cast in pairs and placed tandem fashion, dimensions being 4.3 by 4.7 bore and stroke. The machine has cardan drive, four speeds, 106-inch wheelbase, and is estimated to weigh 2,090 pounds. The only six-cylinder representative is an Aquita-Italiana from Italy.

Among the foreigners there are two eight-cylinder engines, one from the Weigel factory in England, and the Marchand, built by the Dufaux Brothers of Geneva. Here again the cylinders are in pairs, 4.9 bore by 5.9 inches stroke. Chain drive is employed.

Of the thirty-eight machines entered in the race none are attracting so much attention as the three Fiats, to be driven by Nazzaro, Wagner and Lancia. Last year's racers have been conserved and have undergone a careful tuning up and some modifications of the carbureter, about which little is known outside the factory. Cylinder dimensions are 180 by 160 bore and stroke, giving a volume only exceeded by Mercedes. The three machines from the premier German factory are practically a reproduction of last year's models with the new Saurer water jacketed carbureter.

HERKOMER COMPETITORS UNDERGOING SPEED TESTS ON MILITARY GUARDED ROAD IN THE FORSTENRIED PART.

FRANKFORT, Germany, June 16.—The best automobile in Europe—according to the Professor von Herkomer definition—has been discovered in the Benz machine, from the well-known Mannheim factory, driven by Fritz Erle and owned by Herr Ladenburg. In 1905 Ladenburg won the cup, and as the victorious machine driven this year by Engineer Erle of the Benz factory is still Ladenburg's private property, he becomes the permanent possessor of the coveted German tourist trophy. Next year it will be necessary to create a new trophy, the Herkomer Cup being now sportingly deceased, but the task will not be difficult, and it is very probable that the newcomer will have a strong resemblance to the late departed.

Hans Aschoff, on a Metallurgique from Belgium, gained second position; Henri Opel, with a machine from his own factory, captured third prize, and the following in order of merit were: (4) De Lingerke, Mercedes; (5) Karl Neumaier, Benz; (6) Herr Schmierer; (7) Richard Benz, Benz. In addition to these, thirteen machines came through the contest with clean scores, all of them German except Miss Dorothy Levitt and her six-cylinder Napier—both distinctly British.

From Lindau we set out 124 strong on the fourth stage of our seven-day contest, having as accompaniments magnificent weather and heavy, greasy roads, which proved a terror to the smooth-tire men. On the run to Forstenried, over a mountainous road, there were a number of minor mishaps, if the loss of a wheel can be called a minor—but they did not prevent the drivers repairing hurriedly and taking part in the speed test. Willy Poegge, on a Mercedes, showed the fastest burst of speed, covering the 6 kilometers 900 meters, with a flying start, in 2:51:3. Veingand, also on a Mercedes, was a good second; Fitz Erle, on a Benz, came third, and Ladenburg, on a Mercedes, had fourth position. These were the results on net running time. When a classification has been made according to cylinder capacity there may be a slightly different tale to tell.

Arrangements for the speed tests in Forstenried Park were perfect and all passed off without a hitch. An excellent stretch of road, wide, straight, with a good surface, and carefully guarded by troops, allowed of the fastest going. From the standpoint of the numerous spectators there was the additional attraction of fine weather and as fair a piece of landscape as one could wish to look upon.

THE GIANTS TAKE A NOON-DAY REST AT WURZBOURG CONTROL.

Sunday at Munich was a rest day for the cars and drivers, but an exceedingly busy period for the inhabitants, who turned out in thousands to visit the exhibition ground where our automobiles were staged. Quite apart from the cup, a prize was offered for the most luxurious and well-appointed car, which, after a long search, was discovered in the Benz owned by Dr. Pfundt. Probably never before had such a large number of luxuriously appointed automobiles been gathered together, outside of a show, as was to be seen at the Munich exhibition ground, most of them being powerful touring cars with closed bodies and ample protection against sun and rain for the driver. By a comparison of notes during the day, it was possible to forecast with some accuracy the winner of the cup. E. Ladenburg appeared to have the best chance; up to this point he had a clean score, his powerful Mercedes of 140 by 150 bore and stroke starting first every morning and acting as pilot car, giving a distinct advantage.

Hill Climb Weeded Out Several Contestants.

Munich to Augsburg, the sixth stage, is a distance of but 130 miles; as, however, there was a loss of about two hours in organizing the Kesselberg hill climb, the total mileage for the day was sufficient. On the winding, difficult hill there were several accidents, in which machines only were the sufferers. Willy Poegge, a very likely winner up to this point, broke the differential of his Mercedes and had to definitely abandon. Four others were placed hors de combat on one or other of the sharp turns. Mathis, on a Fiat, appeared to be terribly fast, as was also Fitz Erle on M. Ladenburg's Benz. This, however, is but a matter of personal appreciation, all figures in connection with the event being kept by officials and not revealed until the meeting of the jury at the end of the day. It is one of the defects of the Herkomer tour that you never know with any degree of certainty

what position you occupy in the contest, all figures being guarded with as much secrecy as if they were related to matters of national defense.

How the Laggards Were Taken Care of.

Running into Augsburg on the "schluss-wagen," the English for which is "whipper-in," one has an excellent opportunity of judging the infirmities of the weaklings. The whipper-in has to close the march, leaving in the rear only those machines incapable of advancing an-

POWERFUL ELEGANT CLOSED CARS WERE NUMEROUS.

A FRENCH REPRESENTATIVE ON GOOD MOUNTAIN ROADS.

other yard. At times the duties are wearisome, as, for instance, when waiting in the dusk for a big car to fit a couple of new tires. But the rear guard service has its advantages, in that it allows a proper appreciation of the beauties of the scene, and beauty spots on the Herkomer course are never wanting.

Leaving Augsburg at 8 o'clock, with Frankfort, 210 miles away, as final destination, the 128 competitors soon experienced bad weather. Rain fell in torrents, blinding the drivers and putting the roads into a condition which called for the utmost caution to keep the cars right side up. During the day a Pope-Toledo, accompanying the tour on an alcohol experiment, but not taking part in it officially, turned over into a ditch. The occupants were thrown into the hood, all escaping with a shaking. At Wurzburg, where there was a stop for lunch, the weather suddenly changed to as satisfactory a condition as one could imagine, and under a bright sun the second half of the daily task was accomplished and Frankfort entered in triumph. While the jury calculated assiduously to discover which of the 128 survivors should be officially declared the victor, the enthusiastic Frankfurterites cheered, each and all letting loose more enthusiasm than is generally thought to exist in a Teutonic temperament. An official banquet wound up the tour in a dignified military manner; toasts to the Kaiser, the organizing Imperial Club, the victor, the thirteen spotless survivors, and the more numerous group which found black points scored against it, being carried with gusto.

In 1905 the Herkomer trophy was won by E. Ladenburg; the following year R. Stoess proved the victor, and this year Germany is again victorious in the person of Fritz Erle, driving E. Ladenburg's Benz. It is in virtue of his ownership of the winning machine that E. Ladenburg is declared the permanent possessor of the cup. Germany has been victorious all along the line, for of the twenty machines finishing the contest with clean scores

only one is of foreign origin. Benz, the victorious firm, though one of the leading German factories, is but little known outside that country. They are building a new factory at Mannheim, from which 1,000 cars per annum will be produced, and arrangements are being made to open an agency at Paris.

FRANCE AFTER UNIFORM RACE CONDITIONS.

FRANKFORT, Germany, June 17.—Taking advantage of the presence of automobilists from all parts of the world, an international conference of recognized automobile clubs is being held here. France is interested in a uniform regulation for automobile races and has, after agreement with other bodies, put forth the proposition that 1908 races should be held under the following regulations: Minimum weight, 1,100 kilograms (2,420 pounds); maximum fuel allowance, 4.4 gallons per 62.1 miles. Germany brings up nine subjects for discussion.

DE DION WANTS 33,000,000 GALLONS OF ALCOHOL

PARIS, June 12.—France has a present problem in the wine growers' agitation in the south and future difficulties in the increasing cost of gasoline. Marquis de Dion, vice-president of the A. C. F., believes that the automobile can again save France as it saved it a few years ago. In the Chamber of Deputies recently he declared that there are 40,000 automobiles in France consuming about thirty-three millions of gasoline per year. If, instead of using gasoline these 40,000 cars employed home-produced alcohol, the north would no longer be obliged to produce sugar to adulterate the wines of the south, honest wine growers would be free from competing adulterators, and the automobile would have an unlimited supply of fuel. The Marquis has asked for an extraparliamentary commission to consider the matter.

LEAVING A CHARMING BIT OF BAVARIAN SCENERY TO TACKLE THE STEEP GRADE NEAR KESSELBERG.

BALL BEARINGS FOR AUTOMOBILE CONSTRUCTION*

By HENRY HESS.

THE field of usefulness of the ball bearing is as wide as the domain of mechanical engineering, or at least that portion of it which is concerned with the support of rotating or oscillating parts. The limitation imposed on the use of the ball bearing in no sense differs from that imposed on any other element of mechanism. It must be employed in accord with the general prohibition against overloading and in conformity with its individuality. That sounds axiomatic and is self-evident enough; but self-evident as it is, it is all too frequently disregarded. Little information on ball and roller bearings can be found in the usual engineering hand and text books. Generally the subject is dismissed with a casual reference; occasionally a formula for carrying capacity is given, but this is usually wrong. Much matter is scattered through the technical press giving isolated experiences with a few bearings that happened to come within someone's observation. Insufficient information on almost every element that must be considered is undoubtedly responsible for the directly contradictory statements to be found and the generally accepted opinion that ball bearings are suitable only for relatively light loads.

This was the situation as Professor Stribeck found it, when asked to investigate the subject for the German Small Arms and Ammunition Factories of Berlin. This concern, having been induced to go into the manufacture of balls and ball bearings, very soon found itself confronted with the imperative need for a scientific basis, if the manufacture was to be removed from the domain of haphazard blind working, resulting sometimes in success and sometimes in failure, the one as much a result of pure chance as the other and neither the result of science.

With characteristic thoroughness Professor Stribeck took up the subject. He first applied the investigations of such men as Hertz, Auerbach and others, on the deformations of elastic bodies to the development of formulæ for static conditions, then by exhaustive tests, determined constants for the materials and followed with an investigation into the conditions of relative motion, and finally concluded the whole by a long and patiently conducted series of observations with actual bearings, thus not only proving the previous theoretical investigation, but also developing data for the use of the work-a-day designer and engineer. That this labor has been crowned with success is evident enough from a consideration of the uses to which ball bearings constructed along the lines laid down have been put in the last ten years; these include not only light bearings for low and high speeds, but others for carrying the 24-ton armatures of electric flywheel generators at 500 revolutions per minute, etc.

This work of Professor Stribeck's undoubtedly is a classic in its field, so that no apology is needed for annexing a full translation and so making it available to the American engineer.

Translator's Résumé of Professor Stribeck's Report.

For the statements and form of this résumé, the translator is alone responsible, but believes that it may be accepted as a correct condensation of Professor Stribeck's work.

Sliding bearings wear out by abrasion of the carrying surfaces. Ball bearings do not give out from wear and do not wear. They may be ground out by admitting grit, but that is as illegitimate a condition for ball bearings as it is for sliding bearings. The only legitimate cause for the giving out of ball bearings is the stressing of their material beyond the limit of proportionality. Lightly loaded bearings can be so designed as to eliminate this cause and so insure practical indestructibility. For heavily loaded bearings this condition is not realizable within practicable dimensions, but the proportions may be so chosen that the over stressing does not result in breakdown within the lifetime of any mechanism to which the ball bearing is applied.

A knowledge of the elastic qualities of the materials at the hardness under which they are used is imperative. It being the elastic behavior that is important with ball bearings as with all other engineering structures, tests of balls, such as are commonly made to determine ultimate rupture when pressed into a steel plate and using the depth of indentation of the plate or load at which rupture occurs as a measure of ball quality, are not only of no value, but are misleading.

The quality of balls and of ball races must be determined from their behavior under loads in the neighborhood of the elastic limit. Balls may be subjected to loads increasing as the shape of the supporting surface more nearly becomes complementary to that of the ball. A ball running between races having a flat or straight line cross section will not support as great a load as though the section were that of a curvilinear groove. Such groove naturally must never have a curvature equaling that of the ball, since that would substitute sliding for rolling contact.

The frictional resistance of a ball bearing is lower, the less the number of balls. Usually bearings can be designed to have between 10 and 20 balls. As balls are usually made to English inches it is convenient to take one-eighth of an inch as unity.

Some Prime Requirements of Ball Bearings.

Speed of rotation, in so far as it is uniform, does not affect carrying capacity. (This applies to radial bearings, but not to thrust bearings of the collar type; in these the carrying capacity decreases with increase of speed.) But speed is rarely uniform; variations cut down the carrying capacity; sharp variations of small amplitude, particularly at high speed, have the more marked effect. Their reducing action is similar to the battering effect of sharp load variations. *Load variations reduce carrying capacity, the effect increasing with the amount of the load change and the rapidity of such change.* *Accumulated experience* with various classes of mechanisms is so far the only available guide for estimating the reductions in the constants that must be made to take these influences into account.

The carrying capacity of a complete bearing is no greater than that of the weakest cross section that comes under the load. This applies to all those forms which have curved race sections of maximum sustaining capacity, except at a point where an opening is cut to permit the introduction of the balls; such bearings are, as to load carrying capacity, governed by the weaker cross-section at that point.

The calculated carrying capacity can be realized only if all balls sustain their share of the load. It is obvious enough that if a ball is smaller than those on either side of it, it will not carry its share of the load; should it be larger, it will carry more than its share and may be overloaded. Uniformity of ball diameter is essential. The permissible variation in ball diameter will be governed by the deformation produced by a relatively small part of the total bearing load, so that the balance of the load may be distributed over the several balls. Such permissible variations of ball diameters amounts to but little more than one ten-thousandth part of an inch.

High finish of both ball and ball sustaining surfaces is essential. The presence of grinding scratches will very materially cut down the cited values of the constant. Of course this presupposes true surfaces underlying the high polish. It follows from this requirement that rust and acid must be carefully avoided as they are destructive of finish and truth of shape. It may not be amiss to point out that *uniformity of quality of material, of hardness and of structure throughout are essential.* The mischief of using balls having different values is not simply confined to the individual ball; if, for instance, one ball were materially harder and so deformed less than its mates, it would take more load and might therefore overload the material of the race, which would yet be

*Extract from paper read at the Indianapolis, Ind., meeting of the American Society of Mechanical Engineers.

entirely suitable under a division of the bearing load among a larger number of balls.

The *frictional resistance of ball bearings* has, by actual measurement, been found to vary from 0.0011 to 0.0095. These are the coefficients of friction referred to the shaft diameter, thus permitting direct comparison with those of sliding friction. The higher values are due to conditions that cause a preponderance of sliding as compared with rolling friction. It must be remembered that there is no such thing as a bearing having only rolling friction; that might be possible were balls and races made originally with absolute truth of surfaces and were such truth then maintained by the absence of deformation under load. Ball bearings having a coefficient of friction materially above 0.0015 under the greatest allowable load are inadmissible because too shortlived. The high resistance indicates the presence of too large an element of sliding.

A good ball bearing will have a coefficient of friction, independent of the speed within wide limits, and approximating 0.0015. This coefficient will rise to approximately 0.0030 under a reduction of the load to about one-tenth of the maximum.

Suitable Materials for Ball Bearings.

The prohibition against overloading demands recognition of the characteristics of the bearing materials. Any material may be used that will not, under the working load, be so deformed as to prevent pure rolling. That means an absolutely inelastic material and one which unfortunately is, and more than probably will remain, undiscovered. But a slight narrowing is admissible to make the demand read: *Any material may be used that will not, under the working load, deflect enough to prevent substantial rolling.* That recognizes that all materials deform under load. Such deformation means change of shape from the original truth and that in turn will cause some sliding combined with rolling; *this sliding must be held down to the irreducible minimum.* Any material may be used that will not, under the working load, be stressed beyond its elastic limit; that is a limitation which is possible of attainment.

The tooth of time would be worn out against such a bearing. Its design is entirely practicable for light work, but for the heavier loads, the requirements would lead to, usually, impractical dimensions. Fortunately, ball bearings, like various parts of the "Deacon's One Hoss Shay," are satisfactory if they last as long as their associated mechanisms. The requirement may therefore be modified to read: *Any material may be used that will not, under the working load, be stressed sufficiently beyond the proportional limit, to bring about its destruction before the lapse of a desired working life.* These conditions permit the use of practically all of the materials known to mechanical engineering. With very few exceptions, however, the load conditions are such as to demand steels of the highest grades and these most carefully tempered. For automobile use, with which this paper is primarily concerned, no others can be considered. That puts out of the running all merely case hardened materials. In these there is always a more or less sharply defined change of structure at some distance below the surface. Continued working will cause a loosening of the hard shell from the softer core, soon followed by a breaking up and very characteristic flaking of the surface. Usually this flaking is local; its action is increasingly progressive, soon involving the entire bearing.

What has been said of case hardened materials holds true also for those carbon steels in which the hardening is not carried substantially and equally through the entire mass. I have here half of a ball. In this a sharp structural change due to hardening occurs at a fairly uniform depth of one-sixteenth inch below the surface. The ball has evidently been run under conditions which shifted the load over its entire surface; it was used in a running test and then broken to examine its structure. It so happened that the ball was caught just before it was ready to fail by flaking. The entire hardened surface has been loosened from the core in such way as to form an inner ball. Some relative movement of this shell and inner ball has undoubtedly taken place, as is evi-

denced by the polished condition of the inner surfaces. The ball is from a series of tests made to try out various materials; this particular grade is very evidently not suitable.

What is true and required of the ball materials is even more so for the races. With time the ball presents its entire surface to the load, the small vibrations and changes of load being sufficient to frequently bring in a new axis of rotation. Not so the race; that is fixed and so always exposes the same surface element to the load attack.

Absolute Accuracy Is Always Essential.

The requirements of a good ball are:

a. *Truth of shape and size.* The permissible limit of error will vary with the character of the material. In general, the better the latter, that is to say the smaller its deformation under a given load, the more accurate must the ball be. It is evident that, were a ball so much larger than its fellows as not to deform sufficiently under its share of the load to permit the others to carry, that it would then not only itself have to carry more than intended, but would also transmit more than intended to the supporting surfaces of the races. If, on the other hand, the ball were smaller than its mates, it would be underloaded or not loaded at all, and the others correspondingly overloaded. What has been said of variations in ball size, of course, applies similarly to variations from truth of outline.

All requirements will be met if the balls are true to shape within one ten-thousandth part of an inch and if all of the balls used in each individual bearing have a similarly small error in size. It must not be inferred that for materials of lower grade, larger inaccuracies are permissible. Were the load distribution the only factor, that conclusion might be justified; greater inaccuracy of size means greater deformation and therefore greater departure from sphericity and the substitution of too great a percentage of sliding for the rolling aimed at. Considerable initial variations from truth of shape have precisely similar results.

b. *Surface finish to a very high degree is also essential.* What is usually considered a very good finish indeed may be characterized as totally inadequate. The recognition of grinding or polishing marks not only by the bare eye, but with an ordinary pocket reading lens, condemns balls utterly; this is true of a bearing having long life under high loads and speeds. Oft repeated endurance runs under conditions where the finish was the only variable have abundantly proved this, at first unsuspected, fact. This was discovered while investigating an apparently inexplicable difference in lasting qualities. As life is too short for a try out under normal loads, overloads were resorted to; they demonstrated conclusively that the higher the finish, the better the endurance. The high finish must not be of the Brummagem or Reuleaux's "cheap but nasty" variety.

c. *The Elastic limit* should be as high as can be had. A limit of proportionality above the elastic limit is desirable.

d. *The hardness and uniformity of hardness* throughout the mass of the ball to the highest attainable degree is essential.

e. *Correct knowledge* and uniformity are more important than even these requirements of high elastic limit and hardness. It will not do to say that, though some balls of a lot may do better than others, the design may be based on the poorer ones. That would result in the better balls carrying more of their share of the load, much as and with the same bad effects described while considering truth of shape and size. Lower quality, provided it is uniform, can be allowed for. It will then merely affect dimensions.

Ball making machinery has arrived at a very considerable state of perfection; but balls within a limit of one ten-thousandth of an intended size are not yet being made without the sacrifice of other qualities. That is, however, not important beyond having some slight bearing on cost, since it is perfectly feasible to select and grade balls within the desired limit; but the hardware dealer's word for uniformity of size is not a safe guide; he is perfectly honest in throwing odd lots of 5-8-inch balls into one box and in thinking the customer who objects because they vary a half-thousandth, or even two, a "finicky crank."

(To be concluded.)

WHAT AUTO INVENTORS ARE DOING ABROAD

It has always been more or less of a mystery to the average autoist just how the magazine wrench used in connection with dismantable rims for racing, stowed away the nuts so neatly as they were flipped off the rim one after the other and also how it automatically released them for further use when replacing the rim. Just how it works is plain at a glance at the accompanying illustration, and doubtless its extreme simplicity will be the first thing to strike the observer. One of the old types of braces is shown in the illustration, but as the tool is provided with a regular bitstock it is quite evident that the bit may be employed equally well with any brace. The tool is nothing more or less than a socket wrench with sufficient length of hollow stock above it to accommodate the number of nuts required—never more than six in the case of foreign racing rims as shown by the cut. As they are received one by one, they serve to compress a helical spring in the butt of the tool and are retained by an automatic catch at the side, the operator not having to touch

NEW MAGAZINE WRENCH.

them at all. To replace, releasing the catch in question brings the last nut to be taken off at the end of the wrench, a new one coming forward each time the catch is released. The illustrations are taken from *Omnia*.

A Motor with Reciprocating Cylinder.

Rather a novel motor that is of interest as illustrating one of the many forms in which the internal combustion engine may be made is illustrated and described in the *Motor Trader* of recent date. Page Renouf is the inventor and the motor is termed the auto-cooler, and though no special provision has been made for air-cooling, it is claimed that the motor may be dismantled with bare hands after having run for some time. The piston is stationary and integral with the pedestal of the engine, the model built being of the stationary type. Another novel feature of the piston is that it contains the valves in its head, the latter being concentric with the inlet valve lying inside the trunk carrying the exhaust; this stationary piston is fitted with the usual rings. Any extra weight necessary in this part of the motor is said to be more than compensated for by the lightness of the cylinder. Besides this, the impulse being the reverse of that of the standard type of motor, the connecting rods are in tension on both the compression and power strokes, which enables their sectional area to be greatly reduced. It is said that the sum of these factors amounts to a substantial reduction in the weight of the reciprocating parts. These connecting rods are fastened at their

RENOUF'S AUTO-COOLER.

upper ends to two horns and below to two substantial flywheels which are carried on a short straight shaft. Lubrication is effected automatically by the cylinder dipping into a groove formed in the base casting and kept constantly filled with oil, which is thus forced up the cylinder rim by displacement. A standard type of float-feed, atomizing jet carbureter is employed. The appearance of the engine in complete running order is shown by the accompanying illustration reproduced from a photograph.

A Novel Three-Speed Planetary Gear.

Though it has its disadvantages, it also has its good points, and the latter are such that the planetary gear continues to be a factor, although it has all but disappeared from everything but light cars in this country. The Englishman favors the epicyclic, as he dubs it, and study has resulted in the production of ingenious modified types, such as the Adams-Hewitt and the Fairfax, which are planetary gears that are not planetary, as the first employs no orbit or internally toothed rings and the latter has

SECTIONAL DRAWING OF FAIRFAX EPICYCLIC GEAR.

no sun wheel, only the planet pinions and racks being employed. These are referred to in the *Automotor Journal*, which publishes a detailed description of the latter.

The chief advantage gained by the construction found in the Fairfax, as compared with the more usual form, is that it can be made to give a much greater range of gear ratios than is otherwise practicable. For instance, it can be designed to give a ratio of 1 to 14 on one speed, while at the other extreme this ratio may be increased to 1 to 37.03, such is its range. Between these two extremes twelve different gear ratios are possible without changing the final train of pinions. The detailed arrangement of this gear is made plain by the accompanying sectional elevation of one of this type constructed for use on a heavy steam lorry.

In this particular form of the Fairfax gear there is no reverse, as the latter is obtained by reversing the direction of motion of the engine itself. There are only three forward speeds, each of which is obtained by holding stationary one of the brake drums, C, D or E. These drums carry annular racks, with which the planet pinions B₂, B₃ and B₄ mesh. The pinions B₂ and B₄ are mounted on the same spindle, but each of the pinions B₃ is on an independent spindle in conjunction with one of the planets C₁, through which power is transmitted to the rack F₁, on the driving member F, which also carries the large spur gear F₂. Each planet pinion has its duplicate on the spindle diametrically opposite, so that the strains on the mechanism are balanced.

To Prevent Pinching the Inner Tube.

One of the most frequent annoyances in fixing an automobile tire is the danger of nipping the inner tube, with, as a result, the bursting of the air chamber before the car has traveled any great distance. When mounting the tire one hand is engaged in holding up the lug, while the other pushes the beaded edge of the

shoe into position. Failure to do this will result in the tube being held in the fierce grip of the shoe. A French device has been produced by which the lug is held up, leaving both hands free for working on the outer shoe. It is a simple but useful ap-

DEVICE FOR PREVENTING INJURY TO INNER TUBE.

pliance, the construction of which will be readily understood by an examination of the accompanying illustration. Charles Durand, of 178 Boulevard Periere, Paris, is responsible for the tool, which is now being placed on the market.

A Trap for Mischievous Boys.

An English autoist who has probably had his patience taxed by the ubiquitous small boy surrounding his car and taking liberties with it while it is reposing at the curb, has exercised his inventive ingenuity on the problem of devising an effective device to make the inquisitive youth have a wholesome respect for the innocuous looking "buzz-wagon." By taking advantage of the fact that most cars are equipped with high tension coils and carry batteries, he has devised a system which is described in *Motoring Illustrated*. For those who find themselves similarly minded and wish to teach the urchin who would defile the paintwork of a car by scratching his initials on it, the following directions taken in connection with the accompanying diagram of the necessary wiring, will be found useful.

Run a low-tension wire from one of the terminals of a spare battery to a tumbler switch, such as is used for electric lighting. This should be fixed to the dash or under the seats. From the other terminal of this switch run another low-tension wire to one of the two primary coil connections. These usually have dis-

DIAGRAM FOR CONNECTIONS FOR A SHOCKING CIRCUIT.

tinguishing letters, but in a coil which is already coupled up for ignition work they will be those terminals to which low-tension wires are already attached.

Run another low-tension wire from the unoccupied spare battery terminal direct to the second primary coil connection. If

the switch be now closed, the trembler will immediately vibrate, the ordinary ignition circuit being switched off altogether.

Carry a high-tension wire from the secondary coil terminal (*i.e.* that terminal from which a heavy high-tension wire already passes to the distributor or spark plug) to one terminal of a tumbler switch mounted on a porcelain base.

From the other terminal of above switch, run a high-tension wire under the floor to the end of a length of chain sufficient to trail on the ground. Solder the connection between wire and chain. Screw to the underside of floor a hook, upon which to hang the chain when not in use. Secure the wire to the under side of floor by insulated staples, or other suitable means, to obtain firm support from the chain without making electrical contact with the car frame. Do not fasten the chain itself to the floor, unless it be by means of an insulated screw-eye.

If, now, the switch controlling the primary or low-tension circuit be closed, the coil will "buzz," but nothing else will happen until the chain is lowered, and the second switch controlling the high-tension or secondary circuit is also closed. The frame will then be alive, and ready to give a shock to anyone standing on the ground who ventures to touch it. In putting the shocking device out of action, first open the primary switch, then open the secondary switch, and haul up the chain.

The accompanying diagram will make clear the method of connecting up. The existing ignition circuits are shown in dotted lines, thin for low-tension wires, heavy for high-tension wires, the new connections being shown as continuous lines, likewise thin and heavy for the primary and secondary circuits.

In this diagram, B is the spare battery used exclusively for shocking purposes. S and S₁ are switches controlling the primary and secondary circuits; on the latter is the length of chain trailing on the ground. P and P₁ are the primary coil connections, while H T is the secondary or high-tension coil terminal. S₂ is the switch on the ordinary ignition circuit, B₁ being the ignition battery. C is the timer, and D the distributor from a four-cylinder engine using one coil. Cy 1, 2, 3, 4, are the four-cylinder heads, into which the sparking plugs are screwed.

In a car using a number of coils in place of a distributor, any one of the coils could be used for shocking purposes, the others not being interfered with at all. With magneto-fired engines, the connections are exceedingly simple, an additional high-tension wire merely being taken from that terminal to which a wire already is attached from the distributor or sparking plug, to the chain as above indicated, a switch being introduced somewhere along its course to break the shocking circuit when not required. With magneto ignition, the engine must be running all the time the shocking device is in operation, in order to furnish the necessary current. After having installed such a shocking system, doubtless the owner who would chastise the pestiferous small boy will find that he himself is the first to get the benefit of it until he remembers that it is there and working.

PREDICTING THE FUTURE MOTOR OMNIBUS.

Although the motor omnibus has come to stay, it grows daily more and more evident that it will not—indeed, cannot—remain in its present form, concludes the *London Times*, which says:

"Before it can be ranked as a successful vehicle it must be considerably reduced in weight, and therefore to some extent in carrying capacity. If the reform does not come from within, it will assuredly be enforced from without for the wear and tear of suburban roads, the extremely serious deterioration of roadside property, due to the noise and vibration inseparable from these huge cars, are raising most strenuous opposition. A few days ago a deputation from Paris arrived in London for the purpose of investigating the traffic problem as dealt with in this city, and particularly with regard to the motor omnibus question. This deputation had an audience with the chief commissioner of police, who, in the course of his remarks, gave it as his opinion that the motor omnibus of the future must be a much smaller, lighter and quieter vehicle than that at present in use."

LETTERS INTERESTING AND INSTRUCTIVE

Some Questions on Track Records and Ignition.

Editor THE AUTOMOBILE:

[794.]—In your issue of June 6 you credit Cedrino in a Fiat with a world's record for middleweight cars. Did not Frank Kulick, in a 20-horsepower Ford, made up of two Ford double-opposed engines, make a better record than that in the Fall of 1904? I believe he also holds the middleweight one-mile record, generally credited to Cedrino.

Après of the spark question. I have a car equipped with a Remy magneto. I find that on trying a vibrator coil on same when testing for a misfire, that I cannot take a certain hill on the high speed, though the miss is gone; that with the magneto on I ascend easily, though I change nothing else but the coil, and give the right spark amount of spark advance in each case, using even the same distributor and commutator. Could you investigate the question and state the result in your "Letters Interesting and Instructive" columns, and oblige a three-years' subscriber?
T. C. B.

Los Angeles, Cal.

The then existing records for middle-weight cars were broken by Frank Kulick at Narragansett Park, Providence, R. I., September 10, 1904, the times being as follows: One mile, 1:04 1-5; two miles, 2:05; three miles, 3:06 2-5; four miles, 4:07 4-5; five miles, 5:09 4-5. Present records for middle-weight class are: One mile, 0:56 2-5; two miles, 1:52 4-5; three miles, 2:49, made by E. Cedrino, in Fiat, Empire City track, October 27, 1906; four miles, 4:01 3-5, made by Jos. Tracy, in a Renault, Empire City track, September 24, 1904; five miles, 5:00, made by Guy Vaughn, in a Decauville, Syracuse, September 18, 1905. Frank Kulick holds all track records up to and including five miles for light-weight cars, made in a Ford, at Empire City track, the times being as follows: One mile, :55; two miles, 1:54; three miles, 2:51, all made November 8, 1904; four miles, 3:48 2-5; five miles, 4:43 3-5, both made October 29, that year. The time for the one mile was intermediate.

As the magneto generates an alternating current it naturally cannot be used to the same effect with a vibrator coil as with a plain coil, the alternations of the current taking the place of the trembler. When the armature of the trembler is attracted by the core of the coil becoming magnetic the circuit is broken and the surge of current thus sent through the primary is transformed in the secondary winding of the coil. The spring causes the armature to return the moment the magnetic force ceases, owing to the rupture of the current and the moment the blade comes back it again makes contact and the operation is repeated. A magneto, on the other hand, produces a current that surges from zero to its maximum constantly, first in one direction and then in the reverse, hence its name of alternating. The coil in consequence starts to act on the first alternation, but when the trembler returns and again makes contact there is no current and the coil is momentarily dead, which would naturally cause the motor to miss, if its proper time of firing should occur at that point. The armature of the magneto only carries a single winding and, as arranged for ignition purposes, there is a contact breaker set to act at the point of maximum current flux, or peak of the wave as it is termed, so that only two current impulses are utilized per revolution—exactly the number required to fire a four-cylinder engine, the magneto being geared to run at the same speed as the mainshaft of the motor. For a more detailed explanation of the action of the magneto we would refer you to the article which appeared in the issue of THE AUTOMOBILE of April 4, under the title of "How the Magneto is Utilized for Ignition." This makes no definite reference to the use of the coil in the connection explained above, but illustrates the character of the current generated and the manner in which it is utilized on the car. Only a plain or non-vibrating coil should be used with a magneto of the Remy type. A trembler coil may be employed by screwing the former down fast so that it cannot vibrate, but the results are not apt to be as good as with the coil wound especially for the current generated by the magneto.

Proper Point of Stroke at Which to Fire Charge.

Editor THE AUTOMOBILE:

[795.]—I have a 1907 Model G, four-cylinder Franklin, dimensions 3 1/4-inch bore and stroke. I would like to learn through "The Automobile" at what point of the compression stroke the cylinder should fire to obtain the best results with the spark advanced. The cylinder now fires about 1-4 inch before the compression stroke is complete. Is this correct?
CARTON.

St. Louis, Mo.

As the motor of your car is designed to run at a pretty high normal rate of speed, we should think that the position of firing you mention would be about the correct one for the following reasons. The object to be attained is the explosion of the charge at the moment when it will exert its maximum expansive force at the beginning of the power stroke. If it could be assumed that the closing of the primary circuit by the timer of the ignition system, the occurrence of the spark in the cylinder and the subsequent explosion of the charge all took place so close together as to be practically simultaneous, the proper time for the spark to occur would be exactly at the upper dead center or finish of the compression stroke. But such is not the case. There are both electrical and mechanical lags in the ignition system to be accounted for such as the time required to saturate the core of the coil, inertia of the trembler, and the like, and it is also thought that the rate of flame propagation in the mixture is such that this also has to be taken into consideration. This last is a mooted point and doubtless the rate of flame propagation in a compressed mixture is so extremely high that this is not a factor and has no bearing on the subject whatever. The quarter inch before the completion of the compression stroke that you mention is usually termed "lead" and is generally measured in degrees on the arc of the crank circle and marked accordingly on the periphery of the flywheel in order that the motor may be properly reassembled and timed after having been dismantled.

Another Bad Case Similar to No. 781.

Editor THE AUTOMOBILE:

[796.]—Letter No. 781, under heading of "A Bad Case of Heating," describes exactly the trouble I am now having with same kind of car—Marion light touring car, 1905 model. I bought this car new in April, 1905. Ran it the first season over our very rough and hilly roads something over 5,000 miles, carrying four people. Practically, I had no trouble; never broke down or had to be towed. Last season ran the car something over 2,000 miles. As I own two cars, I do not run either all the time.

This season I am using the Marlon as a runabout, and am having just the same trouble as the writer of letter No. 781. Today is a hot one, 90 or over in the shade. Ran the Marlon to Concord (nine miles); on my way home I had trouble; every part of car, including the two passengers, got sizzling hot, engine so hot that it would cook anything; gear drum on countershaft and muffler sizzled. Had to stop engine frequently to let it cool. I cannot say where the trouble is, but I mean to find out and fix it myself if possible.

No. 781 and I are in the same fix. If he can locate the trouble I hope he will write you. If I do, I will.

Air-cooling may not always work as it should; neither does water-cooling. I have seen very high-powered water-cooled cars which got so hot that it came pretty near being dry steam which came out of top of radiator.
C. F. M. STARK.

Dunbarton, N. H.

Your description of the trouble would seem to tally so closely with that given by correspondent No. 781, that undoubtedly the trouble will most likely be found to be the same or something very much akin. The fact that the entire engine and its piping back through the muffler get hot appears to support the rich mixture theory most strongly, as the latter would continue burning not alone on its way out through the exhaust valve but also through the remainder of the piping and so heat the muffler. After a good cleaning up try running on as weak a mixture as the engine will possibly turn over on and then give the fuel admission adjustment a fraction of a turn or so and see

if the trouble does not abate. As mentioned in the answer referred to, a quick-burning mixture is absolutely essential to successful air-cooling, particularly in the early cars of this type.

How Expressions of Analyses Are Read.

Editor THE AUTOMOBILE:

[787.]—I would like to know how to read the expressions generally used in the written analyses of steel. For instance, take the following, referring to the composition of a certain specimen of steel. How would this data be read?

Carbon	Sulphur	Nickel
0.45	0.017	1.17

Also in the report of the strength of aluminum castings published in "The Automobile" of June 6, 1907, I find the following, as expressive of the physical properties of the sample, and would like to know their significance, as well as the way they are read.

Ex-4"	Con.
8.25	9.5 per cent.

Hoping that I have made clear to you the information that I desire, and thanking you for the trouble,
C. C. CROSS.
North Tarrytown, New York.

In speaking of the quantities of the various constituents of a sample of steel as determined by an analysis such as is set forth in your letter, engineers usually speak of these as "carbon point four five," also this particular ingredient is frequently referred to as "10 point carbon, 20 point carbon," and the like. The other quantities are most generally referred to as mentioned just above; that is, "Sulphur point nought one seven," "nickel one point one seven or one point seventeen." Regarding the other abbreviations these refer to the properties of the test piece, the first representing the amount of expansion in the piece tested, the dimension following "ex." or expansion, having reference to the length of the piece in question, so that this should be read, "Expansion in four inches, 8.25 per cent." The second abbreviation refers to the amount of contraction on test in the same piece, so that the dimension is naturally not repeated.

THE WHITE CAR THAT MADE THE HILL-CLIMBS.

Editor THE AUTOMOBILE:

[788.]—I note that in your account of the Cleveland hill-climb in your June 20 issue, in referring to the car with which Walter White made his record climb, you say it is "almost a duplicate in appearance to the famous 'Whistling Billy' of track racing days." This statement is correct except in the following particulars:

- Wheelbase.
- Clearance.
- Length over all.
- Method of suspending frame from axle.
- Size of all working parts.
- Position of generator.
- Position of engine.
- Position of gasoline tank.
- Position of driver's seat.
- Position of steering wheel (as regards which side of car).
- Position of water tank.
- Style and size of bonnet, etc.

I can readily see that your Cleveland correspondent has taken the view, which is so popular with the gasoline people, that our hill-climbing car is a very special affair. As a matter of fact, it is exactly like every other 30-horsepower car that we have built this season, except that it is "tuned up" for hill-climbing work (it is another demonstration of the flexibility of steam power that a standard car, by putting an hour's work on it, can be made to deliver much more power than that for which it is ordinarily adjusted to give).

By "tuning up" I would say, first of all, that, as we can remove our condenser (just as the gasoline cars remove their mufflers), it is possible for us to use a special bonnet, which, of course, gives the car a somewhat rakish appearance. The driver's seat is a slight affair of aluminum placed directly over the generator. We run the car at slightly higher pressure than is required for ordinary touring service. In order to run a White car at a higher pressure, all you need to do is to adjust the "water regulator" with a pair of pliers, as any driver of a White can do in five minutes on the road. We also have a hotter fire than usual by carrying more air pressure on our gasoline tank. This also is something which can be done to any White car ever built at the option of the driver, as any air pressure may be secured by simply putting your foot on the pedal. These, in full, are the changes necessary to make any White car into a "special White racer." We look upon it, as I said before, as simply emphasizing the

flexibility of the White car whereby you can get from it, under all conditions, all the power necessary.

Hill-climbing is the true test of the power of an automobile, and it seems to me significant that we should beat, by such a large margin, such cars as the Darracq, which won the '05 Vanderbilt race, and the six-cylinder Stearns. The former represents the highest development in horsepower per pound of weight. The latter represents the largest cylinder displacement which can be considered as practical. We have an engine the dimensions of which are in all 3x6x4 1-2, and the following is certainly a proposition worth considering:

What would we do to the gasoline cars if we should ever consider it necessary or desirable to add one or two inches to our engine dimensions?

Another interesting fact is that the new regulating system has shown itself to be equally efficient with high pressure as with normal pressures, and all that is necessary for the driver of a "special White racer" to do is to "Just open the throttle and steer."

THE WHITE COMPANY,
New York City. per R. H. Johnston.

PROVIDING A RESERVE SUPPLY OF GASOLINE.

Editor THE AUTOMOBILE:

[799.]—I have noted a recent inquiry in your Letters Interesting and Instructive Department, regarding some simple means of fitting a reserve tank to a car so that an emergency supply of gasoline can always be carried. I am enclosing you a sketch showing how I have done this on my car. There are two connections or supply outlets from the tank, one of which reaches up three inches above the

SIMPLE METHOD OF PROVIDING EMERGENCY FUEL SUPPLY.

bottom of the tank, while the other is level with it; the latter constitutes the draw-off for the reserve supply while the former is the regular supply outlet. This valve (A) is allowed to remain open at all times, while that in the emergency pipe is kept religiously closed. By turning the valve B, a six-gallon reserve supply is tapped and that is certainly sufficient to reach a depot. It is a simple and inexpensive expedient and one that has never failed me.
OLD TIMER.

FOUR YEARS' STEADY RUNNING ON SOLID TIRES.

Editor THE AUTOMOBILE:

[800.]—Answering the letter in your June 13 issue, in which Sol Williams, Cedar Point, Kan., gives "An Opinion on Solid Tires for Small Cars," kindly permit me to say (to your readers who may construe his experience as conclusive evidence) that there are durable cars on the market, also successful solid tires, and that thousands of the latter combination have been used constantly the past four years with entire satisfaction.

Mr. Williams unsuspectingly pays a tribute to solid tires when he says that after two years' use his tires are for sale at half price, admitting that his tires are good for at least four years. He intensifies the compliment by describing the rugged, rocky roads over which his tires have been driven, showing the durability and long life of solids. Mr. Williams may have adopted what he thought would be more resilient spring suspension, but the new springs may be too heavy for the weight of his car, and therefore too stiff to absorb vibration properly, and attributes the trouble all to the tires. If it were usual that such results followed the adoption of solid tires, we would coincide with Mr. Williams, but our experience in the solid tire has been entirely the contrary, and we can show 500 testimonial letters received from patrons in past four years, and all treat the solid tire with words of commendation. We have fitted every type of car from the lightest Orient buckboard to the heavy, luxurious Peerless and Thomas limousines.
Akron, O. A. G. HENDEL.

ENTERING the automobile field a couple of years ago by building a model car with a number of interesting and novel features, the Modern Tool Company of Erie, Pa., put its product through a 10,000-mile test and has just begun to make deliveries to the public of its Payne-Modern automobile. A description of the models is certainly opportune and will doubtless prove interesting to all students of automobiles.

Three models are being produced, a four and six-cylinder touring car and a six-cylinder runabout. The six-cylinder chassis is somewhat heavier than the four-cylinder model, but otherwise the two types are similar. An illustration is shown of the complete four-cylinder chassis and of the six-cylinder touring car.

The motor which is air-cooled on all models, is carried forward under the regulation type of bonnet, is attached direct to the side frame, and has separately cast cylinders set at an angle of 60 degrees. An advantage of this type of engine is that a great saving of space is effected, this being specially noticeable with a six-cylinder motor, and a better circulation of air to the cylinders is secured. All cylinders, on both four and six models, are 4 inches bore by 4 1-2 inches stroke, of refined iron, put through a special process before casting. Under test the cylinders are subjected to a hydraulic pressure of 2,000 pounds to the square inch. Cylinders, piston rings, shafts, etc., are ground dead true and do not vary one-thousandth of an inch.

The cylinders are cooled by means of a peculiar copper fin made in two halves swaged into the iron by means of a split collar and steel ball. This has the advantage of copper radiation, several times as efficient as cast iron, but avoiding the former trouble experienced in making a close union between iron and copper. These cylinders, after being rough-bored and fins mounted, are heated before grinding to relieve any strain that might be in the metal. The air is circulated by

means of two fans, one on the periphery of the flywheel and one governor-controlled fan in front of the cylinders. A peculiarity of the action of the fan is that it furnishes a maximum amount of air when the car is at a low rate of speed ascending a steep hill and the throttle wide open, which corresponds to the greatest heating period of an air-cooled motor. It is well known that in an ordinary air-cooled car as the engine slows down the speed of the fan also is retarded. A further feature which adds

to the success of an air-cooled motor is the exhaust valve, its location and operating mechanism. On the Payne-Modern the valve itself is located on top of the cylinder and the valve pallet in the plane of the cylinder wall in such a manner that when the exhaust valve is opened to relieve the cylinder of the heated gases the gas does not have to pass up through the head of the cylinder or out through the side of the cylinder head, but is at once released. This feature adds to the cooling effect of an air-cooled cylinder, especially inasmuch as the valves themselves are abnormally large.

Valve operation is by a peculiar cam motion in which the cam shaft is offset in relation to the crankshaft, the cam plungers also being offset. Each exhaust valve is provided with its own exhaust pipe, having an internal diameter of 1 3-4 inches, open enough to relieve the back pressure to such an extent that there is no appreciable effect on a gauge. The valves are operated by a walking beam and are held on their seats by a conical spring resting on a spider, which serves to prevent them coming in contact with any heated portion of the exhaust cage. They are held on a taper seat in the cylinder head by means of two studs and a bridge provided with two pressure screws, the exhaust and inlet pipes being attached to the valve cages by means of a breech lock nut. To remove the valve as a unit complete with its springs, etc., it is but necessary to give the inlet pipe or exhaust pipe lock nut an eighth-inch turn and re-

CHASSIS WITH FOUR-CYLINDER MOTOR.

lieve the pressure screws in the bridge, allowing this latter to be swung out of the way and the valve removed complete. High speed steel, which serves to prevent any scalding effect from the heat, is employed for the valve stems; the valve pallets are made of 30 per cent. nickel steel. The distributing chamber has certain peculiarities and appears to provide a solution of the difficulty of obtaining an equal quantity of gas to all six cylinders. The carbureter being designed to slightly enrich the mixture at low engine speeds and make it weaker at high speeds, a wide range of engine flexibility is obtained.

The four-cylinder engine is attached to the side members of the frame by means of four lugs; the six-cylinder motor has three point suspension. Although the main bearings of the engine are extremely long, the rear bearing being 1 3-4 inches by 4 inches and the center bearing 1 3-4 by 3 inches, the overall length of the crankcase is only 36 inches. For the engine bearings a peculiar bronze which is neither phosphor nor white bronze, but which has remarkable wearing qualities, is employed.

The commutator is located on the right hand side of the engine in an accessible position and near it is a small automatic air pump for forcing air to the gasoline tank at the rear. The supply of gasoline is fed to a small auxiliary tank on the dashboard, traveling by gravity to the carbureter. On the dashboard is also a small air gauge and relief valve, which may be adjusted to relieve the pressure at any desired point. One pound pressure is usually sufficient. Lubrication is by means of a McCord oiler under a cowl on the dashboard, driven from the camshaft by a V belt, each cylinder being lubricated separately.

An internal expansion clutch, covered with a special material which will not burn, is employed. Four speeds and reverse are obtained by sliding transmission of the selective type, the lay shaft and all gears being idle on the direct drive. The shafts are lubricated by means of ring oilers; bearings are of phosphor bronze. A detailed examination of the transmission shows that the lay shaft is made hollow and provided with a plunger called a timing knuckle. Balls are set in the recess in the hollow shaft and by means of slipping the timing knuckle are forced to engage in a recess in the gears. The shape of the recess in the gears being such as to make a pocket the same shape as the balls, the strain is not a shearing one, but rather a crushing one from all sides; when it is known that a crushing strain on a 1-2 inch ball (the size used in the transmission) amounts to 39,000 pounds, it is obvious that it would be impossible to crush a sphere from all sides. On the main shaft are two lock rings operating in conjunction with the timing knuckle by means of cams, so that the lay shaft may be set in motion and the male shaft disconnected for operating the gears; similarly for direct drive the front lock ring unlocks the gears driving the lay shaft and the rear ring unlocks the cone on the gears of the male shaft, at the same time locking the male and female shafts. Special Tungsten steel is employed for all operating parts in the transmission, the gears and shafts being of chrome nickel steel and all parts hardened and ground. The gear shipping lever has been placed under the steering wheel, it being believed that this position allows of more convenient operation than the more familiar side lever.

Final drive is by propeller shaft and bevel gears to rear live axle of the floating type, carrying bearings outside the tube. On the six-cylinder machine there are four brakes on the rear axle; the four-cylinder model has two brakes on the rear axle and one on the transmission.

Engine control is by means of spark and throttle lever located above the steering wheel. The change speed gear being operated by a lever under the steering wheel, as already described, and all brakes being controlled by foot levers, the machine can be entirely operated without any necessity for reaching outside, everything being close at hand when the storm side curtains are closed down. There are three foot pedals, the right hand one operating the running brake, the center one the clutch, and the remaining one controlling the ratchet or emergency brake interlocked with the clutch.

BOOKS FOR AUTOMOBILISTS.

Michelin's French Guide Book.—The 1897 edition of the French road book published by Michelin & Cie., the tire manufacturers of Clermont-Ferrand, is a carefully compiled and well-produced volume of over 600 pages, giving all the information which tourists in France are likely to need. It contains an alphabetic list of towns, each of which has a clear road map, and information on hotels, garages and automobile dealers; distances to nearest towns and points of interest in the neighborhood are also mentioned. Great care is taken in recommending only the best hotels and those garages where the traveler will be sure of finding good accommodations. Customs, laws and regulations naturally find a place in the book. A valuable feature is a series of colored maps of various sections of France, and a large colored road map of the entire country. Automobilists visiting Europe can obtain copies of the *Guide Michelin* free on board steamships of the French, White Star, and Hamburg-American lines.

Navigating the Air.—Under the auspices of the Aero Club of America an interesting illustrated volume has just been published by Doubleday, Page & Co., of New York, under the title "Navigating the Air." The volume is a record of personal experiences of the twenty-four men most distinguished to-day in the art and science of flying. Such authorities as Alexander Graham Bell announce that the problem of aerial transportation has been solved, and the book gives for the first time an authentic summary of the present state of this science. Among the contributors are Dr. Bell, the Wright Brothers, Lieut. Lanm, John P. Holland and other famous aeronautical specialists. No attempt is made to trace the history of the new art of navigating the airs, but each writer deals with his own connection with the art in a manner calculated to interest both the practical aeronaut and the general reader. The book contains 32 pages of photographs showing important developments in aerial navigation.

French Automobile Trade Annual.—The thirteenth *Annuaire Général de l'Automobile*, a 500-page directory of the automobile industry in Europe, has just been issued by Thevin & Cie., 1 Rue Villaret-de-Joyeuse, Paris. Published in French by a French firm, it contains a very complete list, classified according to industries, of all firms directly or indirectly connected with the automobile industry. Constructors and dealers in other European countries are given in almost as thorough a manner. Sections of the book include: Alphabetic list of all dealers in Paris and district; names and addresses of all automobile constructors in Europe; dealers, agents and garage proprietors; manufacturers of accessories and supplies; a list of all automobile owners in France, and a list of associations, clubs, newspapers and reviews existing in Europe. Persons having business connections with Europe will find the volume exceedingly useful for ready reference.

Road Handbook of the Automobile Club of France.—Visitors to Europe will find a quantity of useful information in the official *Annuaire de Route* published by the Automobile Club of France, Place de la Concorde, Paris, the eighth edition of which has just appeared. French laws, regulations and taxes, which are always a source of trouble to American visitors, are fully dealt with. A feature of the book is a series of sketches of every important town in France, showing all main roads in and out, and the names of all recommended hotels, together with a statement of the accommodation they can offer. Twenty-five other countries are similarly dealt with. The book is printed in French.

Automobile Industry in Italy.—A guide to the rapidly developing automobile industry in Italy has been produced by L'Automobilc, 12 Via Aurelio Saffi, Milano, consisting of a complete comparative table of the products of every Italian factory and a detailed alphabetic description of mechanical features, extending over about thirty pages.

DENVER, June 21.—Geographically considered, Denver occupies a central location between the Great Lakes and Mississippi river on the east, and the Pacific coast on the west, and is the mid-way point of the central transcontinental railway system, with its branches and connecting systems north and south. Naturally it possesses a splendid position for the facilitation of business—an essential characteristic for the automobile selling industry. Coupled with this excellent mid-west location is the altitude of the city above sea level, some 5,000 feet, at the eastern base of the Rocky mountains, and at the western termination of the great central plateau. The highly rarified atmosphere of the locality makes automobiling a pastime of exceptional pleasure and health-giving qualities, and the excellent roads that abound in the vicinity contribute the finishing touches to the autoist's sense of satisfaction.

that is attractive in a tour of the mountain roads, with their grades and turns and splendid outlooks. It all depends upon the mood you are in, and which will most appeal to you.

A favorite run is that to the prairie by the way of Mount View boulevard, a broad roadway that starts at City Park, the largest of the city's breathing grounds. The road bed is a natural one, and is in fine condition at all seasons of the year, and right here it might be stated that

There are any number of fine runs out of Denver, either to the mountains on the west, or over the prairies on the east, with the mountains always in sight, to remind one of the giant upheaval of the

AUTOING ON MOUNT VIEW BOULEVARD.

earth's crust some millions of years ago, which rent the great continental plain in twain, and tossed heavenward the towering peaks and crags to serve forever as a tribute to the majesty of nature's forces. There is much to praise and admire in a run over the prairie roads these fine spring days, with

Denver is an all-the-year autoing city. During the past winter there have been but six days of snowy weather. The run to Colorado Springs, a distance of 81 miles by road to the south, is one of rare attractiveness to tourists, and is the course upon which the local speed enthusiasts burn up their energy—and their tires. The road extends along the foothills of the Rockies in close proximity to the tracks of the Denver and Rio Grande Railway. There is a climb of some 2,200 feet on the route that leads direct to the Springs, and on the return trip a rise of 1,000 feet has to be negotiated.

EARNING HIS PASSAGE.

The Cherrelyn horse car runs between Englewood and Cherrelyn, two of Denver's suburbs. The horse pulls the car up hill for about one and one-half miles and then rides back on the rear platform.

such a scenic setting in the west, and there is equally much

The present holder of the record over this course is E. Linn Mathewson, of this city, who, in a 40-horsepower Oldsmobile, on March 22 drove to Colorado Springs in two hours and eleven minutes, and made the return trip to Denver in two hours and four minutes, clipping 41 minutes, all told, from the previous record, held by Marvin H. Fechter in a Reo. As the one-stop express trains take two hours and fifteen minutes for the trip each way, it will be seen that the autoing Denverites exceed the speed limit a little, and may be said to be "going some."

To the north of Denver the roads are not as good as they are to the south and east.

REPRESENTATIVE HOUSES IN DENVER'S AUTO ROW.

One soon encounters open country and road which stretches away to Greeley and Cheyenne, while fairly good in spots, is not all that can be desired. The mountains remain in view for miles, although the Medicine Bow range gradually melts away to the northwest, diminishing in the horizon as one goes further north.

Denver has speedily adapted itself to the resultant conditions that come from the activity of the trade and the enthusiasm of the buyer. The organization of the Colorado Automobile Club was the first expression and outgrowth of the local automobiling sentiment in and about Denver, and is the pioneer club of the State, and the leading spirit in the recently organized State Automobile Association, which is a component body of the American Automobile Association. A beautiful home for the Colorado Automobile Club is now assured, and the house will be built on a site selected on Mount View boulevard. Dr. F. L. Bartlett, the energetic president of the club, is the head of the committee in charge of the work.

The development of the trade in Denver within the past few years has been astonishing. There are two manufacturers here, one producing a gasoline car, and the other an electric. The Colburn Automobile Company has recently moved into a well-appointed factory at Colfax avenue and Fifteenth street, and is now producing a four-cylinder 25-horsepower car, with a sliding gear transmission, using the selective type of operation, and having four forward speeds with direct drive on the third. The car is known as the Colburn "Skyscraper," and with full equipment, including top, will sell at \$3,250. In the line of electrics made in this city, there is the Fritchle car, made by Oliver P. Fritchle at his Clarkson street factory. He began the manufacture of electrics two years ago, and the designs embody the runabout Stanhope and Victoria types.

There are nearly a score of auto selling agencies in Denver, and all the leading makes are represented. Trade has opened up with a rush this spring, and everyone connected with the selling industry here takes a roseate view of the future. A decided impetus was given to business by the recent local automobile show, which was held in Coliseum Hall last April, and which was a great success.

But with all Denver has already accomplished in the comparatively short period that the city has been a factor in the industry and the sport of automobiling, we are far from content. The local automobile club has demonstrated that it is an organization that can do things or, to put it in a slightly better way, "get things done," and after all that is what counts. Plans have been made to establish four main highways leading from the city to outlying points on the four points of the compass, and both the Chamber of Commerce and the Real Estate Exchange have been enlisted in aid of the project. The scheme is to make Brighton, Golden, Bennett and Littleton the main connecting points for these driveways, the plan being to connect Bennett either by way of Colfax avenue or Mountview boulevard to a crossroad along the Union Pacific tracks, thence to the end. Downing avenue will be the main northern road as far as Thirty-sixth street, and from there it would turn to Wewetta street and thence out to Brighton. South Broadway or South Logan is suggested as the approach to the southern outlet, the proposal being to include Washington Park and thence south to Littleton, while the Golden road is planned to cross the Fourteenth street viaduct, along Cherry Creek drive to Lake Place, thence to Boulevard F, and from there on West Thirty-eighth avenue will form the western route. At a recent meeting to further the project, T. K. Bartlett of the Good Roads Association presided, E. A. Colburn and W. A. Hoover represented the club, J. P. Hymer was a delegate from the Real Estate Exchange, and W. M. Downing and C. L. Burpee sat for the Chamber of Commerce. The plan is to ask the municipality to put these roadways in shape and maintain them as far as the county lines, while the counties are to be asked to maintain their portions. George E. Kessler, the boulevard and park expert from Kansas City, has been called in consultation and is preparing detailed plans for the improvement.

That Denver is keenly interested in every phase of automobiling is shown by the enthusiasm displayed by its advocates in every branch. The race meeting held on Memorial Day was the most ambitious event of its kind ever held here while the Orphans' Day celebration of June 12 proved that Denver's autoists are as charitable as those of other large cities the country over, though unfortunately that does not entirely serve to convey the meaning it should, as the call for cars did not meet with as generous a response as should have been forthcoming for such a worthy object. But the result showed very plainly what can be done and there is very little doubt that next year people will realize better the object to be accomplished and fall into line in greater numbers to aid the strenuous endeavors of the local club to be responsible for a bright day in the lives of the many homeless children—a day that they will look forward to as the average youngster does to the Fourth and Christmas.

E. Linn Mathewson and H. S. Brinker were the stars of the Decoration Day meet here and autoists, not to mention a large part of the general populace, including, of course, those juvenile hero worshipers that abound here as everywhere, did not let the opportunity pass to show their appreciation of automobile racing on a circular track, as it was naturally the only kind of auto racing they have ever had a chance to see. No less than 6,000 went to Overland Park, the scene of the meet, and the amount of enthusiasm displayed was all out of proportion to the attendance, though this represented a showing far in excess of what has characterized meets of far greater importance that have been held and featured with far greater attractions in Eastern cities, even when the track racing game was at its height. Mathewson has been dubbed the Barney Oldfield of Colorado and Brinker the "little dare devil" for their work with Thomas "forties." Overland Park was the scene of the meet and Denver turned out 6,000 strong to cheer.

When, after some pretty work, Mathewson lowered the world's fifty-mile track record for stock cars from 1:03:19 3-4 to 55:43 2-5 there was an ovation tendered him such as has seldom been granted to any victor of the mile circle here or anywhere else. Pandemonium reigned supreme for a good quarter hour. Following the Mexican custom in showing approval of a particularly clever coup in the bull ring, a large part of the spectators tossed their hats, canes and everything else throwable onto the track and then followed themselves, so that Mathewson was almost mobbed. He had everything his own from start to finish, the 20-horsepower Stevens-Duryea, driven by Ralph W. Smith, which finished second, being two miles behind, while Brinker in the other Thomas "forty" was the victim of a mistaken flag signal, the latter being waved at him as an indication that he was entering on his last lap, when in reality he had only completed forty-eight laps all told. Minor derangements caused him to come to a stop twice during the course of the race, by which he was lapped twice by Mathewson, but in spite of this he stood a good chance to finish a close second had it not been for the error in signaling. Maxwell, who drove the Stevens-Duryea, looked a sure winner at first, holding the lead for six miles, when he was compelled to stop. Mathewson then took first and was not headed again throughout the entire fifty-mile run.

The first race of the day was a five-mile event, with the same entrants as the fifty-mile endurance race, Mathewson finishing an eighth of a mile ahead of Maxwell in the Stevens, Brinker not being in the running owing to two of the plugs giving out at the same time. The only entries in the next race were the 20-horsepower Stevens-Duryea, driven by Maxwell, and Fred Powell in a 30-horsepower Pope-Hartford, the former easily taking the honors. The fourth event was another five-mile race and in this Brinker crossed the line an eighth of a mile ahead of Mathewson, who had been delayed by engine trouble. The two rivals met again in the ten-mile handicap event, which was the seventh on the program, both starting from scratch. Although his time was not very fast—the best mile being done in 1:05 1-2—Brinker again led Mathewson by an eighth-of-a mile.

A FEW MORE OF DENVER'S LEADING AUTO HOUSES.

FIFTEEN kilometers eastward from Pont Aven one strikes the route nationale again at Quimperlé, charmingly situated on a little tidewater river with a couple of admirable old churches, some curious houses and a good café-hotel, the Lion d'Or, on the quai, where you will call if you are wise.

Lorient is twenty-one kilometers east of Quimperlé and is an ugly, unappealing seaport, once the headquarters of the French East India trade. It is the least lovely large town in France, in spite of the fact that it is endowed with a magnificent situation. The hotels and *mécaniciens* are on the same level of mediocrity. The inner man and the automobile will find nothing here that may not be had better elsewhere.

Ten kilometers after Lorient is Hennebont, situated on the estuary of a deep-cut little river, the Blavet. It is all Lorient is not, an ideally picturesque spot with charming promenades along the river banks, some old moss-grown fortifications, innumerable curious old houses, a stupendous late Gothic church and a most excellent hotel with "good enough" garage accommodation. If you have slept at Pont Aven cut your journey here and take déjeuner in this all-sufficient little Breton Hotel de France at Hennebont.

If time presses keep on to Auray, where, at the Lion d'Or, you will do equally well, twenty-eight kilometers farther on.

The monuments of Auray and roundabout are very numerous and interesting. There is a pilgrimage to be made to Ste. Anne d'Auray—where on the 25th of July in each year is held a great religious fête—and the excursion down the great peninsula of Quiberon and through the *Lignes de Carnac*, the name given to a regiment of great stone *menhirs* like those at Stonehenge in England, only here there are thousands instead of scores.

A Glimpse at the Summer Retreat of the "Divine Sarah."

Off-shore, a dozen kilometers, is Belle-Ile, where Fouquet ensconced himself when he fled from the wrath of his King after the great fête of Vaux, and where Aramis of the "Trois Mousquetaires" became a landed proprietor. To-day Belle-Ile is a little island kingdom all by itself, with a capital, Le Palais, a local newspaper and hotels and restaurants, even though a good half of the population have never set foot on the mainland. There are no automobiles on the island, and the greatest celebrity is Sarah Bernhardt, who has a summer home here.

From Auray to Vannes is twenty-odd kilometers, skirting the north shore of the Morbihan, a great inland bay like the Great South Bay of Long Island, with characteristics much the same, except that the picturesque peasant is wanting in America and we have to content ourselves with a gray-bearded old sailor in oilskins and a so'wester instead of a gay gallant with a hat with fluttering ribbons on it, an embroidered vest and tight-fitting trousers with fifty brass buttons down the outside seams.

On the road hereabouts the Breton types are seen at their best, young men and maidens and old men and market-women, but all of them picturesquely clad. They invariably walk in the middle of the road and it takes more than a mere "honk" to make them move; a shrill screech of a siren will do it, but that's about all. It is bad form to use a siren in a French town.

Another warning right here, though it might well have been put at the beginning of this article. There is an infrequency of automobiles in Brittany, and for that reason live stock, particu-

larly horses, donkeys and mules, are easily frightened. There's no pleasure or satisfaction in bolting a donkey cart into a ditch and spilling out its invariable load of lovely femininity—for they are lovely, the little Breton maids. Go slow, then, and be rewarded by smiles instead of frowns.

At all times, when stopping, look carefully over your tires and extract the *sabot* nails, the great flat headed hobnails of the Breton peasant's sabots which drop out in dry weather when the wood around them shrinks. They don't puncture all at once—if you are using what the French call *pneumatiques extra-fortes*. This variety is indeed a necessity all over Europe if one is to avoid slight punctures; these short, pointed, flat-headed nails will not penetrate if your tires are thick enough; if they are not you will suffer continual annoying punctures. In Brittany one must be more careful than elsewhere.

Vannes is a great, big, overgrown country town. It rises to the dignity of being a Préfecture, but is a sad, dull place with inefficient hotels and only interesting for the visitor because of its accessibility to the Golfe de the Morbihan, its old houses, its thirteenth century cathedral, its old city walls and the grim donjon known as the Tour Connétable, in 1387 the prison of Olivier de Clisson.

Pass Vannes by so far as eating or sleeping goes if possible, and keep on to Rochefort-en-Terre or Redon; you will do far better at the Hotel le Cadre at the former place or the Hotel de la Post at the latter. Each abounds in character, a vague term, but one understood of the traveled person. Rochefort-en-Terre is a little artists' paradise exploited almost entirely by French and Americans; *jamais les Anglais*, says the patron of its little next-to-the-soil hotel.

Railroad Crossings Which Only Open Under Protest.

If the atmosphere here is *too* artistic another twenty kilometers brings you to Redon, and if you don't have to wait an interminable while at the railway gates you will be very pleased indeed with your déjeuner eaten in the *salle à manger* of the Hotel de la Poste—one might say the *musée*, for the walls are hung with all sorts of curious trumpery—some of it good, but certainly as great a hodge-podge as was ever collected by a cranky hotel proprietor. Barring this idiosyncrasy he knows well how to run a hotel, though it is abominably situated opposite the railway station and has no pretence to architectural beauty of any kind whatever.

The gates of the railway crossings throughout Brittany, and frequently in other parts of France as well, are often kept closed. This is a protection for the public, of course, and cannot be complained of, beyond wishing that the day may soon come when *all* grade crossings shall be abolished. It's annoying, nevertheless, to be held up at a French railway crossing, or *passage à niveau* to speak the vernacular. Usually it is guarded by a feminine personality of uncertain age, who simply tells you in response to an inquiry, "*On ne passe pas!*" "Where is the train?" you ask, with an absolutely clear view up and down the line for five kilometers, "*Il peut venir,*" she tells you coldly. "Yes, truly, it *may* come; but why does it not come?" You wait perhaps, three, five, ten,

THE AUTOMOBILES IN BRITTANY ARE NOT MANY.

or fifteen minutes at this Robespierre of *passages à niveau*, but the woman is incorruptible—as she should be, that we will not deny. Yes, it *may* come! And when it does come, and you have overheated your motor running it free, or have perhaps stopped it and by some mal-chance cannot make it start up again, you have emotions which cannot even be described, much less put into decent print.

From Redon to Chateaubriant is fifty-four kilometers, and if you have had enough for the day the modest little Hôtel de la Poste will care for you admirably. You will eat of simple fare served by a dainty coiffed Breton maid, and most likely somewhere in the dinner's menu will be a *boudin*, which is a black sausage made of congealed pig's blood—and some other things. You needn't eat it if you don't like; there will be plenty else.

There is a *moyenage* chateau here with pepper-box towers and all the ear-marks of the best Renaissance architecture, and there is a legend concerning the horrors of the time when a certain Comtesse de Chateaubriant was first almost starved to death in a dungeon and then cut into pieces by the surgeons upon the orders of her unworthy spouse. So altogether—what with the *boudin* and the drawing and quartering and a church bell that clangs loudly every quarter hour—there is every prospect of pleasant dreams.

It is from Chateaubriant that the chateau

Vendome is better known than the last half-dozen large towns, and is a most interesting place. Hotel accommodation is scant and not remarkable, though good. But the architectural monuments, the flamboyant Gothic church, the Hotel de Ville, and the Chateau Donjon are worth doing, if only by moonlight after dinner, when peasants and blue hussars wander aimlessly.

From Vendome to Chateaudun is forty-one kilometers, with nothing to hold one's speed down save an excessively dangerous *passage à niveau* at Monplaisir, thirteen kilometers from Vendome, and another at Cloyes, a dozen kilometers before arriving at Chateaudun, with its memories of 1870-71.

Chateaudun (Hôtel du Bon Labourer) is a good place for déjeuner or for the night, but Bonneval, fourteen kilometers farther on toward Chartres, is better—for déjeuner at any rate. The Hôtel de France will give you about the best country fare you will get in France—Chickens, veal, crisp salads, asparagus, strawberries and the like. All are in season between May and September; at any rate, they have four or five months of strawberries—such strawberries as are found only in France.

By Vitray-en-Beauce, through the great grain-growing region of France, one arrives at Chartres, thirty kilometers from Bonneval. From Chartres it is plain sailing and easy going to Paris, via either Rambouillet or Ablis. In either case,

Pont Aven

Cotes du Nord

Roscoff

country of Touraine can best be tapped on returning from the Breton tour.

It is seventy-five kilometers to Angers, the southern gateway, where is opened up the whole Loire Valley and the watersheds of the Vienne, the Indre and the Cher, embracing the best of Renaissance chateaux and the "Garden of France."

As Fast as You Please, but Have an Eye on the Gendarme.

The route back to Paris taking in the chateau country is scarcely prolonged two hundred and fifty kilometers, while the direct road via Laval is a trifle less than four hundred.

As a variation, and since after a Breton tour hills may be presumed to have no horrors for an automobilist, another cross-country route to Paris, omitting the chateau country proper, is via Serge, 40 kilometers; Chateau-Gontier, 24; La Flèche, 54; le Lude, 19; Chateau du Loire, 21, and Vendome, 59. It is a most charming and unconventional itinerary, entirely by second and third class roads, but most excellent roads they are, crossed only here and there by routes nationales, but nearly as good; and when one does get a long, silent stretch, with a gentle slope downhill, he may make any speed he likes and no one to say him nay unless he meets with a brace of strolling gendarmes who are everywhere in the most unexpected places—in France. *Méitez vous, alors!*

THE PICTURESQUE COIFFES OF BRITTANY.

via either Versailles or Sceaux, one strikes the terrible *pavé* of suburban Paris twenty kilometers before the capital is finally reached.

If one is going east to Fontainebleau or the Côte d'Or the route from Chartres is via Ablis, Etamps and la Ferté-Alais. If the north, Normandy or the seaport towns in connection with England are the objectives, suburban Paris can be avoided by crossing the Forêt de Rambouillet and through Houdan to Mantes.

To sum up: The roads of Brittany, the main roads, are excellent, but hilly, and so long as one is ready for surprises of sharp ascents and descents, particularly in the towns, for innumerable sabot nails in his pneumatics, for frightened donkeys, geese and peasants, and for gendarmes always looking for trouble the Breton tour is as enjoyable as any in France.

One must not forget that it is six hundred kilometers out and back from Paris or the Seine Valley before one comes to Brittany proper, and that this will take two or three days travelling, going and coming, besides the eight hundred or more kilometers making the Breton circuit. The itinerary is as follows:

Place	Kilometers	Hotels

BAY STATE HELPS AUTOISTS OBSERVE LAW.

BOSTON, June 24.—In order to assist automobilists in observing the law and to provide the local municipal authorities with a uniform method of warning drivers of motor vehicles, the Massachusetts Highway Commission has just adopted a new series of road signs and plans to supply them to local authorities at a low cost. The signs are on iron plates 16 by 24 inches and are enameled in green with white letters similar to the speed signs which have been in use by the commission for a year or more. They are designed to be erected at right angles to the highway at points 150 feet distant from entering roads, cross roads, corners and curves, at which points the law requires that the speed shall not be in excess of eight miles an hour. In the series is another sign designed to be erected 150 feet from the so-called "thickly settled" limits, within which the speed is 12 miles an hour.

Already the commission has had orders for about 125 of these signs by six or eight towns, and as soon as it becomes generally known that they are available it is anticipated that the signs will be much in demand. The commission believes that with these signs in general use there will be much less friction between automobilists and local authorities, for they will enable the tourist to know just what conditions he is approaching, and if he is as familiar with the law as he should be, there will be no excuse for excessive speed. The signs will also tend, it is thought, to do away with the local speed rules, which are the bane of the automobilist, because by using these signs the authorities may in effect reduce the speed of automobiles at the dangerous points on a road without making a regulation covering the entire road.

With the extra appropriation of \$3,000, which the Legislature granted the Massachusetts Highway Commission to put into effect the system of examinations for professional chauffeurs, outlined in THE AUTOMOBILE of May 9, the commission has now established a complete plan for examinations covering Boston and eight of the principal cities of the State. Two men are engaged in this work, and while one remains in Boston for the purpose of examining applicants every weekday, the other makes a circuit of the State each week, holding examinations in Pittsfield, Springfield, Worcester, Fitchburg, New Bedford, Brockton, Lowell and Salem. About fifty applicants are now being examined each week and it has been found that since the examination system was put in force the applicants are much more familiar with the law and the rules of the roads as well as with the management of their machines than they were formerly. Very few now fail on the written test, the majority of failures being on the technical side. At least 75 per cent. of the applicants, however, are now receiving licenses. The new plan is approved by owners and several men who have purchased cars have brought their chauffeurs and cars to the offices of the Highway Commission and have accompanied them through the driving test.

THAT BOULEVARD TO THE WHITE MTS.

PORTSMOUTH, N. H., June 24.—The construction of the Merrimac Valley highway, authorized by the last session of the New Hampshire legislature, and on which work will soon be in progress, will mean a great advance toward the completion of a good boulevard from Boston to the White Mountains. This line, which will be about 65 miles in length, will be a broad, macadamized road, connecting with the Massachusetts State highway at Tyngsboro and extending northward to Lake Winnepesaukee. It will run through the cities of Nashua, Manchester, Concord, Franklin, and Laconia, in the order named. The expenses for the construction of the road will be jointly defrayed by the State and by the towns and cities through which it will pass.

Automobile "scorching" will hereafter be decidedly unpopular in this neighborhood, as the police have received instructions to arrest all indulging in the practice, or who otherwise fail to comply with the police regulations governing the speed of automobiles, the rate being eight miles an hour.

"GENDARMES ARE EVERYWHERE."]

EXPANSE NEAR BETHPAGE SHOWING PARKWAY STAKED.

BAD WASHOUT MADE CAREFUL DRIVING NECESSARY.

OVER THE LONG ISLAND PARKWAY COURSE

By H. A. GRANT.

IT was a natural bit of curiosity that prompted us to make a run over the Long Island Parkway—that is to be. At present it is a cross-country scramble over widely diversified country, that frequently calls for more acrobatic tricks on the part of the auto than its maker ever intended it to perform. On the great Hempstead Plains, the entrance-hall to the Parkway, there is but a narrow track which has never received much of the tender care of man, but which in a few brief months will be transformed into a broad, rolling highway, where the only speed limit will be that of the car. As far as the eye can see is barren, open country, that breeds a longing to rush away into space at fantastic speed.

Over the broad, grassy plains near Bethpage, as devoid of life as any spot in the far West, except for the presence of the Long Island Railroad, the ground had been staked out for the proposed course, and we stopped the car to get a picture of the very spot on which the Parkway race course will be built. It is an ideal spot for speed, with wide-open land losing itself on the horizon. In its present natural condition to rush over its surface—if that were possible—would fail to produce any sensation of rapid travel, so vast is the expanse; but when a ribbon of road has been rolled out nothing will have been taken from the vastness of the scene and an element will have been added permitting the human mind to grasp the rate at which space is being annihilated.

Further eastward there is more variety—brushes, through wild woodland, with a track so narrow that the undergrowth swishes along the sides of the car, and at times a springy bough strikes you

in the face with a vigorous smack. This will be one of the spots where the traveler will linger to breathe in the beauties of the land. At times there are vistas of sea and land that hold you in contemplation; then again there is bad going, with dangerous washouts that call for undivided attention to keep the car right side up. At present it is too strenuous an occupation, crossing over the Long Island Parkway; but when it has been rolled and hammered and pummeled into the highway it is intended to be, there will be a variety of sensations. At times the only fascination will be to hold the wheel of a high-powered car; at other moments you will be content to jog along on a little single-cylinder trailer.

The residents along the route all seem enthusiastic over the proposed highway; and well they may, for it is the only thing that can make a residential section of an otherwise forsaken country. To be able, almost at the gates of the great city, to find an outlet where dirt and noise can be left behind, and where the fingers can coax the throttle without the eye being in mortal terror of alighting on a blue uniform, would be sufficient pleasure for the automobilist, even if there were no beauty spots.

Certainly this parkway, the first of its kind in the world—for, although others have talked of special motor roads, it has been left to young America to set the lead—will be the precursor of a good-roads movement over the entire country. They will not all be parkways, naturally, but they will all benefit by the example of the perfect highway, on which the skilled engineer to-day and the sturdy laborer to-morrow are to work with might and main.

ABOLISHING CONNECTICUT'S TOLL BRIDGES.

HARTFORD, CONN., June 24.—There is now pending before the Connecticut State legislature a bill providing for the elimination of tolls of the bridges which cross the Connecticut river at Warehouse Point and Thompsonville. The Hon. H. R. Coffin, representative from the town of Windsor Locks, in the house of representatives, is doing his utmost to bring about the passage of the bill. Mr. Coffin has occasion to cross these bridges several times a day. As he uses a 45-horsepower seven-passenger touring car, the tax charges therefor are abominable.

Fred Wright, of the Electric Vehicle Company's test crew, recently crossed the river at Windsor Locks in a 24-horsepower Columbia and was taxed 35 cents for doing so. Wright was so disgusted that he threatened to climb Church street hill on the high, despite the protests of his companion, a mechanic from the factory. Subsequently he made good his threat.

Should this bill pass the legislature, autoists in general will rejoice. These taxes are regarded as relics of the past and there is small reason for their existence. If concerted effort amounts to anything, the bill should pass.

GOOD ROADS NEWS FROM THE FAR WEST.

TACOMA, WASH., June 20.—N. L. Taylor is completing the work of outlining a system of boulevards for this city. The general scheme provides for beginning at the north end of Yakima avenue, thence to Point Defiance Park, around the park along the bluff, overlooking the Sound, and along the ridge of the Narrows to the city limits. Picturesque Old Town is brought into the system. A southern link will run from the south end of Tacoma avenue to McKinley Park. Two other links run to other sections of the city. The estimated cost is \$1,500,000.

State-aid Road Approved for King County.

SEATTLE, WASH., June 20.—The State Board of Highway Commissioners has approved plans for a State-aid road in King county and has elected Surveyor Valentine as superintendent of construction. The estimated cost is \$37,832.57, of which State and county bear an equal share. The road begins at the Riverton drawbridge and continues to Renton Junction, a distance of 15,487 feet. It will be a continuation of the macadam road from the limits of Georgetown to Riverton.

Unparalleled Success of the Sealed Bonnet Contest. Never has the outcome so completely confounded the prophets as was the case in the jocularly dubbed "millinery race" of the Automobile Club of America. When the subject was first broached there was a general howl of disapproval. "Why make it four days when two will be more than enough to finish even the best of them?" said these dissenters. But after the first day's successful completion of the scheduled run by every one of the forty-seven starters, tire trouble alone having been the only thing to mar the event, and of that there was remarkably little, one and all changed their tune completely. "Give us something easy," they said. "We could keep this up for a week and still be going some," was the universal opinion.

Nothing proved so conclusively that lifting the bonnet to tinker here and adjust there is something that is the outgrowth of habit rather than the call of necessity. That more than 80 per cent. of all the cars that started finished with clean scores—and they could finish in no other way under the rules of the contest—is most significant. It proves beyond a doubt the extremely high factor of reliability that now characterizes the modern automobile, and it also means that the Automobile Club of America will have to go into the wholesale jewelry business in order to supply the demand for the cups that are the reward of a perfect score. Equally remarkable is the trivial nature of the few mishaps that put the unfortunate few out of the running. All told, they would not suffice to put one car out for more than half an hour. With a single exception, and that car gave audible signs of being a cripple right at the start, the troubles encountered were of the most insignificant kind, a broken valve spring prob-

ably being the most serious on record, while parted battery wires and the necessity for a little steering gear adjustment which eliminated two cars, show how very slight was the attention required. No contest ever held served to demonstrate the reliability of the up-to-date automobile so tellingly, as well as how very difficult it is to devise some form of competition that will serve to eliminate many cars, even though the test be prolonged.

What Will Be the Next Form of Elimination?

As the direct outcome of the great success that has marked the running of the Automobile Club of America's Sealed Bonnet Contest, there has immediately arisen the query, What next? The rules of the latter were considered so severe at first that it was hardly thought possible that more than a few would survive—and that more by good luck than good management or inherent merit on the part of the car itself, as a broken porcelain spark plug, or a parted battery connection, certainly is no disparagement to a car. It did not take long to show that 600 to 700 miles would never prove a conclusive test under what had in a few hours' running become magically transformed into the most liberal of rules, instead of restrictions that spelled failure for the many.

It is quite evident that the modern stock car will run a long distance at fifteen miles an hour, or a much higher rate of speed, without the slightest necessity for adjustment or stoppage other than that called for by needed replenishments of fuel, oil and water, or those occasioned by tire misfortunes. Taking into account the performances of the many cars in last week's contest and their almost uniform success, it would seem that nothing short of a restricted fuel allowance, in addition to the conditions already imposed, would suffice to cause a greater number to fall by the wayside. Reliability has been developed to such an extent that its relative importance has been greatly diminished; the same is true of endurance. It may safely be said that the modern car possesses both these cardinal virtues in high degree, whatever its make, from all of which it would seem that the time has come to couple with them the matter of economy in all future contests, as it is to the "all around" car that the palm should rightly be awarded.

Conflict of the Sales and Engineering Departments.

In every manufacturing business there are two forces constantly at work, and unfortunately they do not always work in unison toward the same end. They are represented by the manufacturing and the selling interests of the concern and in no other industry have they clashed to such an extent as is true of automobile building. Your average automobile manufacturer is a man of ideas and no mean engineering skill, or, if not, he surrounds himself with the best talent of the kind. In either case the result is the same. The car should be representative of the latest advances in design and, more than that, it should reflect the skill of its designer—it should bristle with original features, resolves the engineer, who goes ahead along that line.

"But," says the selling force, "that is not what the public wants. Cut them out and give us something that sells," and the matter-of-fact sales manager, who may not know the exhaust from the inlet, throws cold water on brilliant engineering designs and outlines his conception of the selling car. The war is then on. It is a familiar story to those in the trade, and its outcome depends on which side gives in first. Needless to add, engineering failures have brought the most thoroughly organized and equipped selling departments down in more than one instance. The first half decade of automobile building in this country was marked by a broad trail of them, and only the financial strength of some of the concerns involved averted total ruin. The public is an ass, no doubt, but while it is all very well to build cars after a theory, they must be sold, and no one knows what will sell better than the sales manager. There is another side to it, of course—the demand on the engineering department for new talking points each season—but that is another story.

HARRY FOSDICK REMOVES TO BROADWAY.

Right upon the heels of the announcement that E. R. Hollander had severed his connection with the Hol-Tan Company, which he was instrumental in organizing, came one of even greater import to the fraternity at large, and that was to the effect that Harry Fosdick would again be seen on New York's automobile row, this time as the vice-president of the Hol-Tan Company. Mr. Fosdick has already tendered his resignation as president of the Harry Fosdick Company of Boston, which handles the Thomas and Fiat cars in that city, though it is understood that he will still retain his interest in the Boston firm. His resignation takes effect July 1 and he will be succeeded by Alfred N. Robbins.

HARRY FOSDICK.

Mr. Fosdick has been closely identified with the business of selling automobiles ever since there have been such things. He discovered the Hub when its sole asset in the shape of an automobile representation consisted of two small stores which handled steamers, and he was one of the two. With the decline of the little "teakettles" in popular favor he became manager of the Winton branch house and he was not long in making the fact known that there was a live man at the head of the Winton interests in the down-east seat of learning and culture. He blazed a Winton trail all over New England. For the past two years he has been president of the company that bears his name and has been largely instrumental in fostering automobile interests in Boston generally, being treasurer of the Boston Automobile Dealers' Association, a member of the touring committee of the Bay State Automobile Association, and a member of this year's show committee, which did such good work.

STRENUOUS LIFE FOR THE FOREIGNERS.

Foreign machines are likely to appear more frequently in American touring and other contests than they have done in the past. At a recent meeting of the Importers' Automobile Salon it was unanimously decided to appoint a committee of four, consisting of Paul Lacroix (Renault), Gaston R. Rheims (C. G. V.), Percy Owen (Biachi), and G. M. MacWilliams (Darracq) to be called the Importers' Trade Contests Committee, to make inquiries and ascertain what contests would tend to elevate the sport and bring out reliable and desirable qualities of cars. G. M. MacWilliams, the originator of the movement, declared to THE AUTOMOBILE representative that he had proposed this committee in order that there should be more adequate representation of the foreign element in American contests. "The committee," he stated, "will examine the conditions of all tests, and if they approve of them will recommend members of the Importers' Salon to enter cars. Although they will be ready to offer suggestions to organizing associations, it is not their intention to conduct any competitions on their own behalf. One or two members ridiculed the notion of foreign cars entering competitions, but the majority declared that in the future they would enter all tests approved by the Trade Contests Committee. As an example of the influence of the movement, had this step been taken a few weeks earlier there would have been, instead of two Darracqs and a Rolls-Royce in the Sealed Bonnet Contest, a group of sixteen or twenty foreign machines."

NEW YORK STATE ASSOCIATION TO MEET HERE.

For the purpose of considering amendments to its constitution, as well as to consider such other business as may come before it, the Board of Directors of the New York State Automobile Association will hold a meeting at the offices of the American Automobile Association, 437 Fifth avenue, New York City, at noon on Friday, June 28.

NEW DEVELOPMENTS IN SHOW SITUATION.

Recently S. A. Miles, manager of the Chicago show, which is to be held from November 30 to December 7 this year, sent out an announcement that the allotments of space for the two Chicago shows—that is, the exhibit of pleasure vehicles and accessories in the Coliseum and First Regiment Armory and that of commercial vehicles at the Seventh Regiment Armory—would be made on July 1, and further, that applications, in order to be considered in the first allotment, would have to be in hand by June 29, application blanks and diagrams being forwarded with the announcement. All of which showed that the National Association and Mr. Miles were up betimes on show business, as it still lacks five months of the Chicago dates.

Whether this announcement, made in the regular course of routine business, had any bearing upon later developments in the show situation, that have literally sprung out of the ground as it were, is a question. But that developments of a rather revolutionary nature are pending seems to be assured. It is a matter of common surmise that the National Association of Automobile Manufacturers, under whose auspices the Chicago show is held, and the Association of Licensed Automobile Manufacturers, the upholders of the Selden patent, are closely affiliated, and there is a feeling in the camp of the American Motor Car Manufacturers' Association that the latter element has become dominant, with the result that independent makers are to be discriminated against. There will accordingly be a meeting of the latter Association in New York City to-day, June 27, to decide whether to exhibit at Chicago this year or not, and it is thought that any action taken will be followed by the Motor and Accessory Manufacturers, Inc. As the members of these two associations have always formed a very substantial part of the Windy City exhibit, their defection is a matter of some moment. Whether the question of holding an entirely independent show in the West, as has been the case in New York, will be brought up at the meeting, remains to be seen, but judging from the present outlook there will be a break.

BIG ENTRY FOR THE POINT BREEZE 24-HOUR.

PHILADELPHIA, June 24.—Next Friday and Saturday's twice-round-the-clock event at Point Breeze promises to be the most important event of the kind, as regards the number of entries, which has yet been held in this country. The Quaker City Motor Club, which is managing the affair, will spend considerable money getting the track in shape, with a view of preventing its wearing into ruts, as it did in last month's race. Six thousand gallons of crude oil will be worked into the track this week and heavy rollers will be at work from dawn to dark pounding the stubborn clay into a solid level surface. Although the entries have not yet closed, there are already two Lozier, two Wayne, two Frayer-Miller, and the same number of Dragon cars listed to start, besides one each of the Mitchell, Darracq, Pennsylvania, American Mercedes, Stearns and Oldsmobile. At least one more entry is expected and possibly two, and if so Starter Wayne Davis will be compelled to line up the field in two rows, as the track is not sufficiently wide to accommodate all of them abreast.

GOLD CUP TOUR DEPARTURE DELAYED.

Latest despatches from Georges Dupuy, manager of the Gold Cup tour, state that after running through the whole of France, north of Spain, and a large portion of Italy, the Stearns and its occupants are at Rome, preparing to strike northward into Austria and Germany for the final stages of the journey.

Owing to the late start and various delays on the road the pilot car is far behind the schedule. "The machine is pulling splendidly," says the Gold Cup pioneer, "but 200 kilometers a day for 50 days in succession is a terrible strain on the driver." In a few days the party will sail for New York, arriving here early in July, when a definite announcement will immediately be made on the date of departure of the main body.

JUNETIME DOINGS OF THE AUTO CLUBS

Worcester Holds Successful Decorative Parade.

WORCESTER, MASS., June 24.—This city had a four-days old home carnival last week, and Thursday afternoon the feature of the closing day was an automobile parade. This parade was originally planned by the carnival management to be held in connection with a coaching parade and show of workhorses. Members of Worcester Automobile Club showed the fallacy of this and succeeded in getting the autos into a separate division,

A BEAUTY-LADEN PRIZE-WINNING THOMAS FLYER.

and with prefatory policemen mounted on motorcycles, and the band on a motor truck, were able to roll along at a fair rate of speed through the business section of the city and past City Hall, where Mayor John T. Duggan reviewed it.

There were nearly fifty cars, mostly decorated, in the line. The largest cup offered was awarded to John S. Harrington, who put his Thomas Flyer into the competition decorated with pink and white and pretty girls. A cup for the best equipped touring car, occupants and their costumes to be inclined in the make-up of the car, went to a Rainier car from the Buck-Price Co., Boston, Fred Smith driving. A cup for the best decorated runabout went to Oakley S. Walker, who with his daughter, Miss Dorothy Waiker, traveled in a Ford runabout with tasteful decorations. The committee of award were George A. Campbell, P. B. Talbott and Dr. Roy M. Garfield.

Worcester Automobile Club members are planning for summer runs. Among them Col. Fergus A. Easton will take his Stevens-Duryea to the White Mountains, thence across New Hampshire and Vermont to Montreal, thence to Toronto, Kingston and Hamilton and home by way of Niagara Falls and across New York State. C. C. Milton and J. E. Fuller are planning a trip through Vermont to Ticonderoga and the Lake George region, and home by way of Saratoga and the Berkshires. Lyman F. Gordon is planning to initiate a new Packard car by accepting delivery at the factory at Detroit and running it home.

Syracuse Autoists Enjoy an Era of Prosperity.

SYRACUSE, N. Y., June 25.—Forthy-three members were added to the Automobile Club of Syracuse at its most recent meeting, the largest number elected at any one time since the club was organized. The club now has a membership of 155. Secretary Forman W. Wilkinson was requested to communicate with the authorities in an effort to have the highway between Fayetteville and Oneida placed in better condition, as this route is a favorite one with automobilists and is in sad need of attention. It was decided to issue a folder for general distribution calling attention to the objects of the club and what has already been accomplished.

Comment was made upon the large danger signs placed at the top of the Tully hill, and it was announced that information had been secured by President H. W. Smith and others for the placing in Onondaga County of one hundred additional route and danger signs which have been ordered. As many of the roads in this section of the State abound in bad spots, these signs will be much appreciated.

A motion was passed rescinding a resolution adopted at a former meeting requesting Senator Horace White to dispose of his stock in one of the toll road companies. It was found that the club had been misinformed and that Senator White did not own any stock in a toll road. A letter of apology was sent some time ago.

Georgian Automobilists Organize at Atlanta.

ATLANTA, GA., June 24.—For the purpose of having representation with the American Automobile Association, a meeting was held last week in the Piedmont Hotel by owners of machines in Atlanta and the Atlanta Automobile and Goods Roads Association was organized. The new organization is a business one and has for its purpose the securing of proper legislation for the protection of auto owners, the betterment of the roads and advantages in accident policies and machine insurance.

The meeting was well attended and the following officers were elected: President, F. L. Seeley; vice-presidents, E. H. Inman, R. F. Shedden and J. P. Stevens; secretary, E. H. Crocker; treasurer, Asa G. Candler, Jr. All owners of autos are eligible and the dues are two dollars a year.

L. I. A. C. Becomes Joint Promoter of Brighton Beach Race.

The Long Island Automobile Club has become associated with the United States Motor Racing Association in the running of the twenty-four-hour Automobile Endurance Derby, to be held at Brighton Beach track on August 9-10. The well-known Brooklyn organization will appoint all the officials for the contest and otherwise generally supervise it. R. G. Kelsey, chairman of the contest committee of the Long Island club, is taking a very active part in arranging the details. Plans have been made to include a fifty and a hundred mile race in the Brighton Beach program, holding these events in the afternoon and early evening of August 9, starting the twenty-four-hour race later the same day.

GAYLY DECORATED MAXWELL-BRISCOE FACTORY BUILDINGS AND THE CROWD THAT WITNESSED THE CEREMONY.

NEW MAXWELL PLANT DEDICATED.

NEWCASTLE, IND., June 22.—This is the day that the famous discovery of Newcastle by Benjamin Briscoe is being celebrated. Of course, Newcastle has been here for some time on the same spot, but no one in the automobile industry knew anything about it until the far-seeing Briscoe put the inducements of Muncie, Marion, South Bend, Elkhart and Kokomo behind him and struck out on his own line. Newcastle had a good deal to do with it, too, because while the others were haggling over terms its progressive citizens formed the Industrial Company and landed the Maxwell-Briscoe Motor Company in its midst. Consequently Newcastle is celebrating to-day and a right royal celebration it is, too. The occasion is the laying of the cornerstone of the immense new plant where Maxwells are to be turned out, but unlike most of the formal functions of this kind, progress has not been delayed on that account and the big buildings are more than half up.

To say that Newcastle celebrated is to put it mildly indeed. Every one of the 5,000 inhabitants of this little "city of roses" was there and as many more from the surrounding country. Business was entirely suspended and so far as this particular

portion of the United States was concerned it might just as well have been a national holiday. As a prelude to the formal ceremonies at the new plant there was one of the most ambitious automobile parades that Indiana has ever seen. Carl J. Fisher, the Indiana Maxwell agent, drove here at the head of a long procession of Maxwells, and his line was considerably swelled by the local owners, so that there was a string of more than a hundred cars. These served to carry the officers of the Maxwell-Briscoe Motor Company, Vice-President Fairbanks and the other guests of honor, who occupied six touring cars, while the remainder were given over to the members of the many fraternal organizations who helped to swell the crowd, which was estimated at over 10,000 people. The ceremonies were opened by an address of welcome by E. H. Bundy, one of the town's leading citizens, who was followed by Vice-President Fairbanks, the principal speaker of the day. It is evident that politics have not so engrossed the Vice-President's attention but that he is keenly alive to the immense future of the automobile industry, as well as its ultimate trend toward the production of moderate-priced cars on a vast scale. Naturally he drew a roseate picture of the great growth and promising future that lay before Newcastle owing to its en-

MR. MAXWELL MAKES AN ADDRESS TO THE MULTITUDE.

VICE-PRESIDENT FAIRBANKS, THE MAYOR, AND MR. BRISCOE.

VICE-PRESIDENT FAIRBANKS LAYING THE CORNERSTONE.

try as a factor in the automobile industry, and incidentally he reviewed the rapid strides made by the latter.

To put it in the vernacular, the committee on arrangements knew its business, for an address by C. S. Henley on "Greater Newcastle" and another by M. E. Forkner concluded the speech-making. Next to the actual laying of the cornerstone the great feature of the day was to be a banquet, but the attendance so far exceeded all estimates that it was necessary to make the big dinner a continuous performance. In fact, there were three of them, the first two installments being held at the Bundy Hotel two hours apart, and the other at the Country Club later in the evening.

The story of how Newcastle came to get the Maxwell-Briscoe plant is an interesting one. The terms agreed upon involved a site valued at approximately \$30,000 and a bonus of \$90,000, to be applied to the construction of the plant. In return for this the company agreed to establish a factory that would employ at least 1,200 men and keep it in operation until \$2,000,000 in wages had been paid. But raising a bonus of \$120,000 in a town of 5,000 people is no small task, and the manner in which it was successfully accomplished may well be patterned after by growing towns which find themselves in a similar position. A tract of land was purchased, plotted off into building lots, and on November 13, 1906, the town had a huge block of carefully marked out lots as its sole asset to induce the establishment there of what will probably be the largest automobile manufacturing plant in the country. That was the day the sale began, and in just four days there was such a demand for the lots that the contract was ratified by the directors of the Maxwell-Briscoe Motor Company and received its final validation in the shape of the signature of the Industrial Company just one week later. No time was lost in beginning construction, the first contracts being awarded on December 22. Work has progressed so rapidly since then that it is expected the main factory building will be complete in time to turn out some of the 1908 Maxwells.

As it is a typical example of the truly vast scale upon which American automobile plants are now being built, some statistics regarding its size will not be as dry as such figures usually are. The main building is of brick and concrete construction, involving the use of 1,000 tons of steel, and measures 722 by 316 feet. The manner in which things have been rushed on is evidenced by the fact that it is almost ready for the roof. In addition to this, the present plans include a 50 by 75 foot office building and an independent power plant housed in a special structure measuring 200 by 50 feet, and a 200 by 60 foot building for testing. These constitute the nucleus around which the plant will spread until it eventually covers the entire sixty-five acres of ground available, including a half-mile track for trying out cars. Sev-

eral carloads of machinery have already arrived here to form part of the equipment and will shortly be installed, it being expected that operations will begin early in the fall. That the sponsors of the new plant expect to greatly exceed the provisions of their contract calling for the employment of 1,200 men is shown by the fact that the washroom equipment of the main building includes 2,026 individual lockers, and it is said that fully 1,500 employees will be put to work right from the start. It is understood that at first only the Model H Maxwells will be built here, but as soon as it is running full blast the new plant is expected to have an annual capacity of 5,000 complete cars, which is somewhat of an increase over the total output of 500 cars turned out in 1905 and 1906 by this company.

SCHEDULES SHOW LARGE NOMINAL ASSETS.

Schedules in bankruptcy of the firm of Smith & Mabley, incorporated, which recently went to the wall, have just been made public. They show total liabilities of \$296,188, of which \$90,000 are contingent, consisting of three damage suits for personal injuries; the nominal assets total \$513,661 and the available assets \$167,241. The last named consist of automobiles, supplies, accessories; outstanding accounts to the sum of \$64,578; equity in accounts assigned, \$2,614; cash, \$557; unexpired insurance, \$1,600; 360 shares of the stock of the Smith & Mabley Manufacturing Company of a par value of \$36,000 and pledged for a loan of \$25,000; plant and power account, good will, etc., carried on the books as representing \$346,420, and the office furniture and fittings at 1765 Broadway inventoried at \$61,892.

The liabilities consist of the claims of some 210 creditors, some of the chief of whom are Boessneck Broessel, \$116,200, partly secured; New Amsterdam National Bank, \$24,000; Riverside Bank, \$165,500; W. H. Hull & Company, Bridgeport, Conn., \$6,117; Bridgeport Vehicle Company, \$5,999; Harry Monkhouse, Rome, N. Y., \$3,638; Standard Oil Company, \$2,698; Harburg Tire Company, now the Crescent Auto Parts Company, \$1,714, and the New York Edison Company, \$1,419. Of the actual liabilities but \$25,562 are secured.

CARTERCAR RUNABOUT AS A FIRE FIGHTER.

Detroit has shown its appreciation of the advantages of the automobile in general as an aid to fire-fighting, and of the Cartercar in particular for this rôle, by purchasing a runabout of the latter make for the exclusive use of Master Mechanic Bresnahan of the city's fire department. This is the second car purchased by the municipal authorities for this purpose from the Motor Car Company of Detroit, the first Cartercar having been bought last year for the use of Superintendent Gascoigne, of the fire alarm system, for his official use.

MASTER MECHANIC BRESNAHAN'S NEW CARTERCAR.

Michigan's Latest Production

The Menges

DESIGNER AND BUILDER, A. C. MENGES, IS AT THE WHEEL, WITH CHARLES CHILDS, GAS ENGINE SPECIALIST, BESIDE HIM.

GRAND RAPIDS, MICH., June 24.—Michigan's furniture city has again come to the fore with a novel automobile production which bids fair to make her distinguished in the industry if the car is built here for the market. A. C. Menges, who has long been identified with the technical side of automobile building, is the sponsor of the new production, and those who have been familiar with his work in the past along this line will not be surprised to note the numerous original features which mark his latest success. The power plant consists of a four-cylinder vertical water-cooled motor. With the exception of this and the fact that it is water-cooled, its adherence to standard practice does not extend any further. Cylinders are cast independently and are perfectly smooth outside, as both valves are located in the head, the valve system being the most distinctive feature of the motor. The valve casings are ground and seated in a tapered housing so as to require no packing. Though located in the head, no rocker arms are used to operate the valves, the springs being set to one side, while the valve lifters, cams and camshaft are housed separately from the crankcase and run in a bath of oil. The exhaust cams are fixed to the camshaft and the operation of this part of the motor is substantially that recognized by standard practice. The intake cams, however, are movable on their supporting shaft at the will of the operator and are called bypass cams, constituting the most important feature of the motor control. By the use of this arrangement each cylinder may be throttled independently; it is, in brief, a system of variable

inlet-valve control by means of which the quantity of the charge inspired is regulated, this in turn altering the compression in the cylinders and in consequence the amount of power developed. These especially constructed cams are supported on a sliding shaft, and as at present designed their control furnishes a means of giving the engine an initial compression ranging from one pound to eighty pounds to the square inch and a horsepower output of from five to ninety horsepower, the fuel consumption naturally being in accordance, the cylinder dimensions being 6 1-2 inch bore by a 5 7-8 inch stroke.

Any one who knows Menges would be safe in stating that a motor which was the work of his hand and brain would incorporate self-starting as one of its distinctive features, and this is the case here. But this is something quite different than has been attempted in the past. It consists of an electric motor which turns the engine over through the medium of a pinion and ratchet. Presumably, the motor is wound for a low voltage and is designed to take its current from the accumulators, though no details are as yet forthcoming on this point. Another rather distinctive feature is to be found in the ignition. Both low and high-tension systems are used, employing the same spark plugs interchangeably, while the current is furnished by a magneto which is driven by a short independent shaft at the right hand side of the motor. A Schebler carbureter constitutes this essential of the motor, though the latter is distinguished by the use of a somewhat original form of intake manifold, as will be seen

RIGHT SIDE OF MOTOR SHOWING MECHANISM.

TOP VIEW OF MOTOR SHOWING OPERATIVE PARTS.

REAR VIEW OF CHASSIS SHOWING DIFFERENTIAL.

from the accompanying illustration showing the power plant as viewed from this side. Another photograph, showing it in about half-plan view, gives some idea both of the motor and its constructional details as well as its odd form of suspension, the latter being patterned after the system of hanging locomotive engines. That is, it rests upon springs with six independent points of support. It is claimed for this that no amount of disalignment of the different wheels in passing over obstructions can cause the frame to spring or the transmission to bind. The continuous circulating system of lubrication that is coming to be more and more favored by designers has been adopted. The oil is pumped out of the base of the engine, one lead sufficing to carry it to all the important bearings, this naturally being supplemented by the splashing of the supply in the crankcase; the oil supply is filtered every time it passes through the pump, so that practically fresh oil is brought into contact with the wearing parts at all times. The fan, water pump and oil pump are all positively driven through bevel gearing.

The first step in the transmission of the power consists of an internal expanding clutch encased with and forming part of the flywheel. From this a long propeller shaft extends to the gear set, which is located on the rear axle and is housed in the same casing as the differential and drive. This is known as the Pleukharp transmission, the mounting and external appearance of which are well illustrated by the rear view of the chassis. This gear set is distinguished by the fact that all the pinions are not alone constantly in mesh, but that on all the speeds, including the reverse, the drive is direct—an arrangement for which high efficiency is claimed. There can be no clashing in making gear changes, and it is not necessary to disengage the clutch to drop from high into low speed, as this can be done at any speed without noise or jar.

The foundation of the chassis consists of channel section pressed steel frame of the standard type, but the suspension is distinguished by the use of four semi-elliptic springs, the location and mounting of which are made plain in the illustration showing the rear axle unit already referred to. These are hung on each side of the frame and the use of four permits of the employment of a much lighter spring, thus giving greater resiliency. Forward the suspension is of the standard type, using semi-elliptic flat springs. This is also true of the brake system which consists of a set of internal expanding and external contracting brakes centered on drums on the rear hubs. The wheelbase is 123 inches and the gage standard 36 by 4 1-2 inch wheels being employed, while detachable tires of this size are used on front and rear. The front axle is a one-piece nickel-steel I-beam forging. The steering gear is of the worm-and-sector type. As shown by the photograph at the head of the page, an attractive type of straight line body with ample sized mud guards has been fitted. A. C. Menges, the designer and builder of the car, is shown at the wheel in this picture with Charles Childs, an expert gas engine man, sitting at his left. Control is by means

of the usual spark and gas levers mounted on a stationary quadrant over the steering wheel.

The four-cylinder car above described is designed to sell at \$6,000, and several of them are now in course of construction. It is the intention of Mr. Menges to head a company which he will shortly organize to manufacture the machines, his plans also contemplating the construction of a six-cylinder car to sell at \$2,000. Inducements are piling in upon him to establish the proposed factory in various cities of this State, but no action has been taken on this as yet.

QUAKER CITY'S AUTO TRANSIT CO. WINNING.

PHILADELPHIA, June 24.—After repeated rebuffs the Philadelphia Auto Transit Company seems to be in a fair way of attaining its long-sought ends. On Thursday last there was introduced in Councils an ordinance framed to meet the objections of Mayor Reyburn who had vetoed the last measure passed by Councils on the ground that it was "too general." In view of the numerous lemons which have been handed the Auto Transit people in the past, there is a disposition manifest among the municipal solons to give the new bill the right of way, and it promises to go through a-humming under suspension of the rules.

At any rate, the company is making preparations to inaugurate its first service—the Broad and Diamond streets line—on July 15, the day of the opening of the monster Elks convention here. Meanwhile work is being rushed on the new power house and garage at Thirty-first and Dauphin streets. Four steam turbines of 150 horsepower each will furnish power for the dynamos. Twenty double-deckers are completed, ready for the opening of the line, and thirty more are under way.

COLUMBIA INAUGURATES SUMMER SCHOOL.

Though it has been customary to hold a summer session at Columbia in a number of branches, courses in civil and mechanical engineering will be taken up for the first time this year, the subjects including Gas Engines, Hydraulics, Structures, Concrete Steel and Experimental Engineering, the principal object being to meet a demand from instructors in engineering schools and technical graduates who desire to keep pace with the progress of recent years in these branches.

STODDARD-DAYTON PRODUCES TAXIMETER CAB.

American gasoline taximeter cabs, so plentiful on paper, so rare in material form, have received another member to their thin ranks in the shape of a unit from the Stoddard-Dayton factory at Dayton, O. The Stoddard-Dayton, a photograph of which is given, is ready for shipment and will almost immediately be seen in active service. In general design it follows the lines of the most successful European taximeter cabs, with the power plant forward, shaft drive and an elegant landaulet body which can be opened or closed at will.

STODDARD-DAYTON TAXIMETER CAB READY FOR USE.

VOLUME III., OFFICIAL BLUE BOOK.

The map on this page is a fac-simile reproduction of the double-page map of Pennsylvania from Volume III. of the Official Automobile Blue Book, published this week by the Class Journal Company, publishers of THE AUTOMOBILE. With Volume I covering New York State and Canada, with extension routes into the Middle West, and Volume II covering New England, with extension routes into the Provinces, it completes the 1907 series of the national touring guide. The entire work includes over 800 routes, describing in the aggregate over 50,000 miles of American roads, with route maps the greater part of the way and local diagrams showing the entrances and exits for nearly all the cities and the most important towns.

Special interest attaches to the Pennsylvania map from the fact that for the first time the State has been taken up as a whole and charted out comprehensively for the guidance of the automobile tourist. Pennsylvania has not been in the past, and is not now, a good touring State throughout; but it has some of the best runs in the United States, particularly in the Eastern part. Moreover, its roads, like its railways, are important links between the East and the West. This is exemplified in the 1907 Glidden Tour, which is coming East from Columbus, Ohio, by way of Pittsburg, Greenburg, Bedford and Chambersburg; thence southward to Baltimore, returning into Pennsylvania again for the final run to Philadelphia and New York.

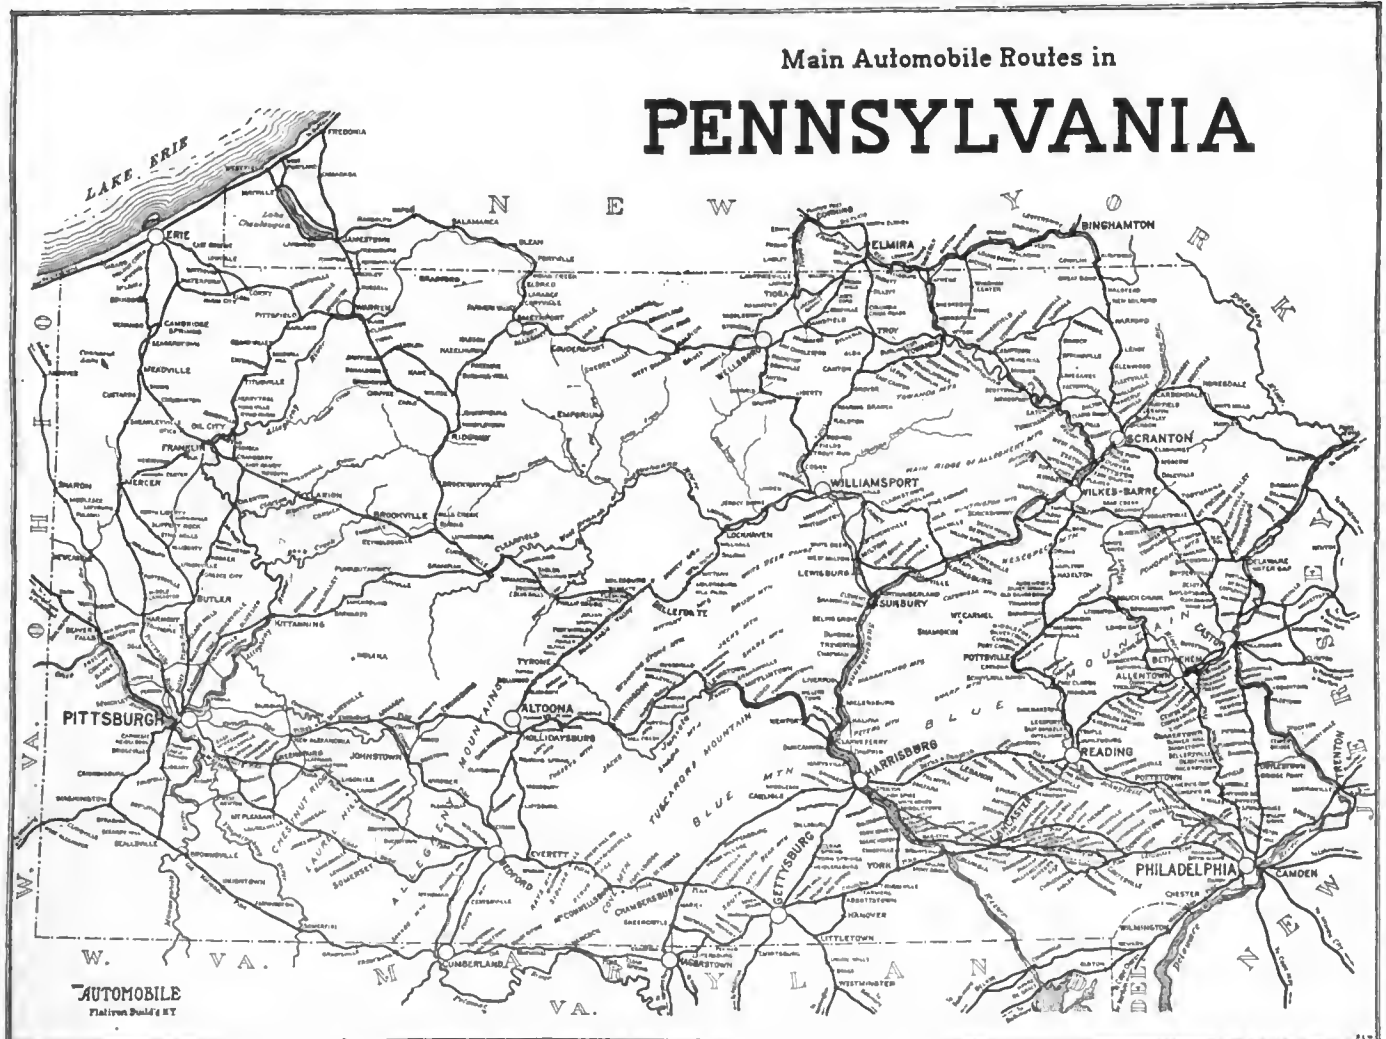

The average of Pennsylvania roads leaves something to be desired; also Pennsylvania laws; and the toll-gate survives in some parts of the Keystone State in an acute form. But here as elsewhere things are changing for the better, and this will be more and more the case as touring increases in popularity. This result will be materially advanced by the large amount of up-to-date material in Volume III of the Blue Book.

REPAIRING SHERIDAN DRIVEWAY NORTH OF CHICAGO.

SHERIDAN DRIVEWAY SEVERELY INJURED.

CHICAGO, June 17.—Chicago and lake shore automobilists have had a narrow escape from losing a long stretch of their favorite driveway, the famous Sheridan drive that is planned to eventually reach from Chicago to Milwaukee. Lake Michigan during the last three months has had such a continuous stirring by high winds as to break any past record for bad weather. The waters were driven over the sheathing that had been planted out in the lake, and attacked the embankments of the roadway. South of Evanston the road lays between the eastern fence of Calvary cemetery and the lake shore. It is but a narrow strip at best, and it was this piece of roadway that the fiercely driven spray fairly lapped away until there was little more than a passage way.

AUTOMOBILE MAP OF PENNSYLVANIA, WITH PRINCIPAL CONNECTIONS INTO THE ADJOINING STATES.

AMUSING CHAPTER OF SELDEN LITIGATION.

Last week was productive of a somewhat diverting side-show in what has popularly come to be known as the Selden litigation—that is, the action of the Electric Vehicle Company vs. the Ford Motor Company over the Selden patent. There was a try-out of the "old gas buggy," which is said to represent Mr. Selden's first efforts, as well as of the duplicate car built on the same lines as an exhibit in the case. These trials took place Saturday, June 15, and Monday, June 17, at the old Guttenberg race track and were supposedly very much sub rosa—so much so that they were commented on by at least one of the motor papers last week and a fully illustrated account appeared in one of New York's dailies on Sunday, June 23.

Then the press bureaus of the two organizations took to the typewriter and the duplicating machine. Quite contrary to precedent, the defense came out with a full statement several days in advance, characterizing the whole affair as a lame attempt to make capital out of the trial; further, that Mr. Selden had requested that no publicity be given the affair, and that the trial was not ordered by the court, as claimed; and that the "1877" label on the old car is the most ancient thing about it, barring the original cylinder casting, as the remainder has all been rebuilt, with considerable more of similar import, not omitting the fact that the first day's trials were a fiasco and the second were not much better. R. A. Parker, of counsel for the defense, is quoted at length on the matter, giving his reason for his statement as the bad faith of his opponents in rushing into print when there had been a mutual understanding that no publicity was to be given the affair.

Apart from the Sunday newspaper story nothing was heard from the publicity bureau of the Licensed Association until Wednesday morning, when a full set of photographs and the complainant's side of the case were sent out—entirely too late for publication in this week's issue of THE AUTOMOBILE. According to the matter accompanying the pictures, both the old car and its new duplicate made a most excellent showing of their powers of running and hill-climbing, the latter consisting of the grade to the paddock of the old track.

GRAND PRIX AND GERMAN RULES FOR BRESCIA.

PARIS, June 19.—Disappointed last year by the adverse action of the government, the Automobile Club of Milan now announces its 1907 Brescia meeting, in Northern Italy, with a great flourish. There are two distinct races, one for racing machines of any power compatible with a fuel allowance of 6.6 gallons per 62.6 miles. In all essential features it is a second edition of the French Grand Prix, and will doubtless be competed by most of the starters in the French event. The Velocity Cup, a \$5,000 trophy, will go to the victorious driver, and the engineer of the car will be awarded the cup of the Automobile Club of Milan.

The second race is for so-called touring cars with a maximum cylinder volume of eight liters. Gasoline of the specific gravity of 680 to 720 must be used, wheelbase must not be less than 118 inches and weight not lower than 2,585 pounds. There are a few other conditions regulating the nature of dashboard, height of seats and road clearance, etc., every feature of the German Emperor's race being embodied in the regulations.

IMPORTERS WOULD EMULATE PARIS SALON.

Official confirmation of December 28 to January 4 as the date of the Importers' Salon in Madison Square Garden has been made by the show committee. A uniform system of decoration, announced as something distinctly foreign and artistic, will be adopted, and the event will be known as "The Parisian Salon Transported." André Massenat has been appointed chairman of the show committee; E. R. Hollander is treasurer; C. R. Mabley secretary and manager, and E. Lillie will be responsible for Italian and English exhibits.

KULICK MAKES NEW RECORDS IN FORD SIX.

DETROIT, MICH., June 24.—In the twenty-four-hour race at the State Fair Grounds, which ended at 10 o'clock Saturday night, Frank Kulick, at the wheel of a 40-horsepower six-cylinder Ford, carried off all the honors. In addition to beating the world's record for that time by the very substantial margin of 309 miles, his total for the twenty-four hours footing up 1,135 miles, he also smashed many track records for intermediate distances. At the end of nine hours he had covered 429 miles at an average speed of 47.2 miles an hour, as against the best former track record of 33 miles an hour. In ten hours he went 480 miles, or an average of 48 miles an hour flat, while at the twelve-hour mark he raised this to 592 miles, or an average of 49.33 miles an hour. His record at fourteen hours was 684 miles and at fifteen hours 731 miles, his running being most consistent.

At the latter point Herbert H. Lytle, in the Pope-Toledo Vanderbilt Cup racer, was second with 724 miles to his credit, followed by Charles Coey, in a 60-horsepower Thomas, with 649 miles. At the finish Lytle had made 1,109 miles and Coey 997 miles. The only mishap of the day which might have been a serious one was caused by a tire bursting on Lytle's car, sending it through the fence a complete wreck. He escaped injury and got his reserve car into action within a few minutes. The other scores ranged from 798 miles down to 713. The car driven by Eddie Bald and "Kid McCoy" dropped out.

INDEPENDENCE DAY RACES AT LOWELL.

LOWELL, MASS., June 25.—Straightaway road races will be held on the Lowell-Kingsbury Boulevard on the afternoon of July 4. Events provided for are a five-mile contest for 35-horsepower cars and up; a five-mile race for 60-horsepower machines; a mile standing start and a mile flying start free for all. A silver cup is offered by the Heinze Electric Company, of Lowell, for each of the five-mile races. The course is six miles long.

BERKSHIRE ASSOCIATION PLANS FIRST MEET.

READING, PA., June 25.—Ten events for all types of gasoline and steam automobiles constitutes the program arranged by the Berkshire Automobile Racing Association on the Shillington track on July 4. Distances are two, three and five miles, and the machines provided for cover all classes from motorcycles costing \$225 to touring cars costing up to \$5,000.

MANAGER J. L. SNOW AND HIS PEERLESS ON BLUE HILL.

Blue Hill Observatory is located on the top of Blue Hill, near Boston, a few miles to the south of the city, and is the highest point of land on the Atlantic Coast from Maine to Florida. The property is controlled by the park commissioners, and autos are barred. A footpath leads to the top; also a winding road, which is very steep and rough.

BRIEF ITEMS OF NEWS AND TRADE MISCELLANY

It has remained for the Thomas Flyer testers at the Buffalo plant to attach a most appropriate cognomen to the motorcycle "cops," who blossom each spring and whose duty is to exert a restraining hand on those who are tempted to "let her out." Henceforth Buffalonians will know them as "corn-poppers."

In a way the winners in the recent Herkomer tour, which is generally credited with being the most strenuous event of its kind held on the Continent, won a victory for an American manufacturer, the first and second cars to finish in the tour as well as the third to come in after the hot contest for the Emperor's Cup using Vacuum Mobiloils for lubrication.

As a result of the greatly increased demand for Witherbee storage batteries, particularly from Canadian points and the Middle West of the United States, the makers have found it necessary to increase the facilities of their branch factory at Detroit, Mich., which supplies this territory. C. E. Brelsford has recently been placed in charge of this plant and is making things hum.

Miller Brothers, of Amesbury, Mass., who are pioneers in the automobile body building business, have recently found it necessary to double their facilities in order to take care of the demand. Their plant now occupies a five-story building measuring 65 by 220 feet and employing 125 men. They are now devoting their entire attention to automobile work and turn out bodies complete, either finished or in the white.

Three Dragon cars have been entered in the Chicago Motor Club's reliability run to be held on June 28 by the Branstetter Motor Company. The route of the run is via Libertyville, Half Day, Wauconda and McHenry to Waukegan, and is so arranged that the touring cars and high-powered runabouts will have to travel 170 miles and the small cars and runabouts about 146 miles. A large entry list has already been made up.

When last heard from the 24-horsepower Premier touring car that is making a non-stop road run under the auspices of the Bridgeport Automobile Club had covered 4,017 miles and was still going strongly. This means that the engine has been running continuously for 384 hours without a single adjustment having been made. The run started on June 3 and as many as ten passengers have been carried at one time to demonstrate the car's power.

Still another manufacturer has become convinced of the fact that shock absorbers are a necessary part of a car's regular equipment. This is the Dayton Motor Car Company, Dayton, O., who build the well-known Stoddard-Dayton cars and who have just placed an order for sixty sets of the Truffault-Hartford shock absorbers for some of their 1908 output. This makes eighteen manufacturers in all who now equip their cars in this manner.

It takes a western sporting man to really originate language of the truly descriptive kind as witness this from this "Tex." Rickard of Goldfield, Nev., on his reasons for buying a 40-horsepower Acme touring car. "I decided to pay my good cash for this machine," he says, "because it is not built with a tin engine and a papier mache transmission nor wooden springs, and a cheap

car would stand no show out here at all, so I plunged on quality."

As part of its sales campaign, G. E. Risley and D. C. Lull, of the Electric Vehicle Company's sales department, are making a tour of the State of Maine, Mr. Risley driving a 24-horsepower, and Mr. Lull a 45-horsepower Columbia. Both cars were driven to Boston and from there shipped to Bangor. Mr. Risley has a large following in Maine and Mr. Lull is well known for his performances behind the wheel, having participated in the New York-Chicago record-breaking run.

Kenneth A. Skinner, one of the veteran automobile dealers at the Hub, suffered a severe loss early last week through the destruction of his fine garage building in the Back Bay district of Boston by fire. The watchman who discovered the fire succeeded in saving a few small cars, but three imported limousines, a number of touring cars and runabouts, as well as a number of cars on storage, were destroyed, the loss being estimated at \$50,000. Mr. Skinner's portion of this aggregates about \$25,000, only partially covered by insurance.

That there is no sign of a falling off in the demand for the Franklin air-cooled cars is quite evident from the fact that their makers—the H. H. Franklin Manufacturing Company, Syracuse, N. Y.—have just found it necessary to add another reinforced concrete building to their already extensive plant. This measures 60 by 100 feet, is five stories high and will increase the capacity of the plant by 300 more cars a season. The contract calls for its completion at the end of ninety days and, when running, the company's pay roll will be swelled to 2,000.

For the first time in a long while an electric has come to the front in competition with gasoline cars. This was a Baker roadster driven by E. Gruentfeldt, chief engineer of the Baker Motor Vehicle Company, who showed what an electric can do in the way of hill climbing at the Cleveland Automobile Club's meet at Stucky Hill. The latter was a stiff test, but the Baker made it in 1:41 2-5, beating the time of eighteen gasoline cars and coming within a few seconds of the best performance of the stripped cars. The run was made from a standing start.

Denmark is coming to the fore as an automobile country, and it is significant that an American car—a two-cylinder Reo—should have been one of the few to finish with a perfect score in the most strenuous contest ever held there. This was a reliability run held over a 300 kilometer hilly course in the vicinity of Copenhagen by the automobile club of that city on May 26. That this is not an isolated instance is evidenced by the fact that a Reo won a silver cup in its class in the Bridgeport hill climb and was one of the first five to finish in the strenuous Albany run of the New York Motor Club.

Under the direction of F. A. Drake, New York manager of the Fisk Rubber Company, a Locomobile touring car has been equipped with the new Fisk removable rims and heavy car type tires and will be driven from Albany, N. Y., to Cleveland, O., by way of Troy, Schenectady, Binghamton, Elmira, Syracuse, Utica, Rochester and Buffalo. At the latter place it will be turned over to Mr. Zimmerman, Chicago repre-

sentative of the Fisk company, who will drive it to Cleveland, where the car is to enter the Glidden tour. Stops will be made at the cities mentioned to demonstrate the merits of the new tire.

Ten thousand miles in a 50-horsepower Apperson touring car with a broken spring as the only work necessary on the car is the record made by Calvin Smith, of Chicago, in a tour abroad from which he has just returned. But for this mishap, which was caused by the car dropping off a small wooden bridge while running through part of the Alps at night, Mr. Smith would have had a perfectly clean score to report. He included Spain in his itinerary—that land of poor roads and worse accommodations that is religiously avoided by the tourist. His car is to be used on an attempt at the New York-Chicago record this week.

Record-breaking shipments of gasoline cars have become a matter of more or less common occurrence, but it has remained for the Columbus Buggy Company, of Columbus, O., to set up a standard in this field where electricians are concerned. These makers recently made a ten-car shipment consisting of forty electric automobiles to their western New York State agent, A. V. Hart, at Rochester, N. Y., which is believed to overtop anything of its kind. The makers of electricians are usually as quiet about their doings as are their cars in running, but this is one that gives some idea of the extent of the demand for these easy-going town cars.

With the recent addition of a large steam hammer and other increases to the facilities of their already extensive plant, the Anderson Forge & Machine Company, of Detroit, Mich., are in a position to do a considerable amount of general forging beside their specialty of making engine crankshafts for which their machine shop equipment is particularly designed. This brings the plant's facilities up to twenty-one hammers of various sizes, so that it is equipped to manufacture an extensive range of drop forged parts for automobile work. A new building, measuring 40 by 150 feet, and two stories in height, has also been erected for a die room, the additions representing an outlay of \$150,000.

A few years ago Death Valley was considered impassable even to the automobile, but now it is included in record runs as witness the performance of a 35-horsepower Peerless touring car which was driven the entire distance from Rhyolite, Nev., to Los Angeles, Cal., a stretch of 400 miles in a little over two days. With Dick Allen at the wheel and Fred H. Vahrenkamp and a party in the tonneau, the start was made from the former place on Tuesday at 11 A. M. and Los Angeles was reached the following Thursday at 1:30 P. M. Allen is known as the youngest driver in Nevada, but brought the car through without a mishap, and though the sand was often up to the hubs in parts of Death Valley on Wednesday the car made 200 miles.

NEW AGENCIES ESTABLISHED.

Pirelli & Company, large manufacturers of cable and rubber goods, at Milan, Italy, will open an American branch for their tire department at 296 Broadway, New York.

A new branch house has been established at Broad street and Fairmont avenue, Phil-

adelphia, by the Goodyear Tire and Rubber Company. A thoroughly fitted up repair plant, including a steam vulcanizer, is among its appointments. L. S. Hall will manage the branch.

The Bellefield Motor Company, of Pittsburgh, Pa., has taken the agency in that territory for the De Luxe cars. The company has a seven-story garage building adjacent to the Schenley Hotel and Duquesne Gardens. A new company has been formed in Chicago to handle the De Luxe, to be known as the De Luxe Motor Sales Company, with a capital stock of \$50,000. The De Luxe has been handled this season in Chicago by the McDuffee Automobile Company.

Two more of Pennsylvania's prominent automobile factories—the Dragon and the Pennsylvania—established local branches in Philadelphia last week. The Pennsylvania secured representation within the charmed circle when the West-Stillman Motor Car Company opened quarters last Saturday at 153 North Broad street. Besides the Pennsylvania, the new firm will handle the Mercedes, Mr. Stillman having been the former local representative of the Mercedes Import Company. E. P. West, the other member of the firm, is a newcomer in the trade. The Dragon salesrooms have been established at 143 South Broad street, across the street from the Bellevue-Stratford. A. B. Cumner has been appointed manager.

PERSONAL TRADE MENTION.

Otto C. Owen, brother of R. M. Owen, has been appointed manager of the Chicago branch of R. M. Owen & Company, to succeed L. J. Ollier, who has gone to California to engage in business at Los Angeles. Mr. Owen has been identified with the Reo and Premier Chicago branch for some time as assistant manager.

J. B. Kavanaugh, for some time manager of the Cleveland branch of the Hartford Rubber Works Company, has resigned. He was for a number of years on the road for the Hartford people and did very effective work. P. H. Goodall, for several years representative for Hartford tires on the road in Ohio territory, has been appointed branch manager at Cleveland to succeed Mr. Kavanaugh.

Several additions have recently been made to the H. H. Franklin Mfg. Co.'s force, notably George Ostendorph, formerly branch manager for the Hartford Rubber Works Company at Buffalo; H. B. Henly, of the New York Motor Company, and George E. Messer, of the H-O Company at Buffalo. These men are now at the Franklin factory at Syracuse taking a thorough course of instruction in their new duties.

Walter Keenan, formerly manager of the Standard Oil Company's interests at Dayton, O., has taken the general management of Speedwell Motor Car Company, of that city. This concern is one of Dayton's new enterprises, and the organization is a very strong one, headed by P. A. Schenck, president of the Dayton Malleable Iron Company, and M. Sternberger, of Jackson, O., president of the Superior Coal Company.

NEW TRADE PUBLICATIONS.

The Pratt & Whitney Company, of Hartford, Conn., has sent out a complete catalogue of over 200 pages descriptive of tools in general use. At the end of the book is a series of tables of English measurements and their metric values.

Enclosed within a dainty cover, the 16-page catalogue of the Traveler automobile, manufactured by the Bellefontaine

Automobile Company, Bellefontaine, Ohio, deals with the two models manufactured by this company. They are Model A, an air-cooled machine, and Model B, a water-cooled. Details of construction and illustrations of parts are given in the booklet.

It is a useful little book of about eighty pages that has been sent forth by the Diamond Rubber Company, Akron, Ohio, containing useful information to all tire dealers. Descriptions of various types of pneumatics, solids, and single tube tires of all dimensions are given, together with complete price list. The Marsh rim is given considerable attention, and instructions are presented for dismantling and mounting it.

INFORMATION FOR AUTO USERS.

New Automatic Gas Generator.—Some important and much-needed improvements in acetylene gas generators are claimed by the makers of the Peterson New Automatic Generator, the O. W.

SECTIONAL VIEW PETERSON GENERATOR.

Petersen Manufacturing Company, 1253 Michigan avenue, Chicago, Ill. Chief among these is a positively automatic water control which automatically adjusts the rate of gas production to suit the number of lights burning so that no hand adjustments whatever are necessary. The Peterson device consists of a

WATER CONTROL.

The automatic tossing carbide basket insures a constant rotation of the fresh carbide to the top next to water, while

the spent carbide is passed down next to the grate, where the ash is eliminated. The basket is hung on its upper edge at one side by a helical spring, from which it obtains its movement. The performance of this generator in practice substantiates the claims of its makers, so that the device is proving popular with the trade.

Weiss Siren Horn.—L. T. Weiss is the inventor of a new and improved type of siren horn which is now being marketed by the Motor Accessories Company, 14 Dutch street, New York. The improvement consists chiefly of the use of a revolving sound-producing member of but a fraction of the weight ordinarily employed for this purpose, thus entirely eliminating not alone the objectionable vibration usually set up, but also obviating all risk of breaking off at the shaft. Its extremely light weight gives it a minimum of inertia, so that the horn sounds the moment the friction pulley comes in contact with the flywheel. A universal joint is fitted to the pulley-holding connection, making it a simple matter to attach, while a neat appliance carries the flexible tube centrally, eliminating all objectionable wiring.

A Glass Window Spark Plug.—To be able to look through a window into the cylinder and observe the conditions under which the engine is working is an advantage obvious to all automobilists. A spark plug which allows of this has been produced under the name of the Anderson and is being handled by W. E. Hutton of 350 Fulton street, Brooklyn. Instead of porcelain, the insulation is of glass welded to the steel case and of the same expansi-

SECTIONAL AND PROSPECTIVE GLASS PLUG.

bility as the steel. The method of filling the case with molted glass is the subject of a patent, the process employed being of such a nature that the glass and steel expand together, removing all risk of cracking. A couple of plugs observed under working conditions recently showed with what facility a missing cylinder was detected, and how readily carbureter and ignition adjustments could be made. Another feature of the plug is that there are three sparking points instead of one.

SOME GRIST FROM UNCLE SAM'S PATENT MILL.

Control for Gasoline-Electric System.

This invention comprises a control for automobiles of the type in which the driving wheels are independently rotated by

the large bevels shown, the result being that while in mesh with the left-hand one, as shown, the vehicle will run backward, and when engaged with the other will run forward.

LEMP'S SYSTEM OF ELECTRIC CONTROL.

The invention has for its chief object the elimination of the reversing gear from the change speed gear-box, thus simplifying the latter by the removal of this pinion, without at the same time introducing a corresponding amount of complication in the differential gear on the rear axle, where any addi-

independent series-wound electric motors—more commonly known as the gasoline-electric system, as the current is generated by a dynamo rotated by a gasoline motor of the usual type. The object is to provide novel connections for electrically braking the vehicle to prevent skidding by manipulating the electrical relation of the motors to one another, as well as the relation of their parts. It consists of the combination of a vehicle having independently rotatable driving wheels on its opposite sides with series-wound electric motors mechanically connected thereto. A resistance and controlling switch is adapted to short-circuit the motors through the resistance with their fields in series and their armatures in parallel. The tendency to skid is thus automatically compensated for, as the motors, and consequently the driving wheels, are kept running at the same speed.

tional weight or mechanism would be even less desirable than in the gear-set. Simple provision for effecting the change is made by equipping the forward end of the propeller shaft with the usual universal joint and an operating lever, as shown mounted on the case enclosing the moving shaft.

The inventor and patentee is William A. Slater, Cedar Point, Kan.

Improved Steering Gear Connection.

In the present instance, the object of the invention is to simplify the mechanism which operates the crank arm which controls the movement of the connecting rods to the steering wheels. The arrangement of the parts is such that the steering wheels may be turned from one extreme to the other with a minimum of movement of the steering post, and positively locked in their adjusted position without unduly straining the parts of the steering mechanism, or causing excessive vibration of the steering post while the steering wheels are passing over obstructions. In outline, the invention consists of the use of two moving members concentric with and adapted to be moved upon the steering pillar by the revolution of the latter, and two arms, fastened at one end to opposite points on the

interior of the housing and at their other ends, to the two moving members just mentioned, as shown.

The inventor is Arthur E. Rockwell, of Oswego, N. Y.

A New Electric Transmission.

This invention consists of the combination of an automobile running gear or chassis, complete, whereon is mounted a prime mover such as the gasoline motor of

REDUCING MOVEMENT STEERING GEAR.

the type usually employed for this purpose, driving an electric generator, supplying current to electric motors attached directly to the rear wheels, there being no mechanical connection between the prime mover and the road wheels. The invention consists mainly in so arranging the controlling lever for the engine of the vehicle, that while in normal operation it will remain in the position in which it is placed, while if the electrical circuit is broken, it will return automatically to the lowest speed position, means being provided in the electric circuit for holding it in such position.

The inventor is Herman Lemp, of Lynn, Mass., the patent being assigned to the General Electric Company, of Schenectady, N. Y.

COMBINATION OF REVERSE AND DIFFERENTIAL.

The inventor is Herman Lemp, Lynn, Mass., the patent being assigned to the General Electric Company, Schenectady, New York.

Combined Reverse and Differential Gear.

A novel form of combination reverse and differential gear is covered by this invention, which permits of only using such pinions as are necessary to provide the required forward speeds in the change speed gear box. The differential is of the usual spur type and instead of having one large bevel pinion, is provided with two of the same size, facing each other. The propeller shafting carrying the small driving bevel is adapted to be shifted laterally so as to permit of its engagement with either of

GENERAL ELECTRIC CO.'S SYSTEM OF GASOLINE-ELECTRIC TRANSMISSION.

Specially reported for THE AUTOMOBILE by Beeler & Robb, Patent Lawyers, Washington, D. C.

Cars For Sale

AUTOMOBILE in running order; has new cylinder, 6 1/2-inch bore; two-piston engine, sliding gear transmission, two ahead and reverse; 32x4-inch rear and 32x3-inch front tires; haven't been punctured; old cylinder tested 21-h.p.; first offer \$350 takes it. M. P., care The Automobile.

AUTOMOBILES—\$75 to \$2,750; a number of slightly used motor cars which have been taken in trade are offered for sale at extremely low prices; all have been gone over and placed in first-class condition. Seven-passenger Thomas and Pierce touring cars, 40 and 50-h.p., \$1,750 to \$2,750; 5-passenger Thomas, Pierce, Packard, Winton, Rambler and Pope-Hartford touring cars, 24, 28 and 40-h.p., \$650 to \$1,600; 2, 3 and 4-passenger Thomas, Pierce, Olds, Packard, Pope-Hartford and Winton runabouts, \$75 to \$350; write for particulars. C. T. Faxson, 1200 Niagara St., Buffalo, N. Y.

AUTOMOBILE BARGAINS—A square deal to all. Good cars are not necessarily expensive, and are not hard to find if you call at our salesroom. We have all makes, and every car is put in first-class condition before being offered for sale; our prices are the lowest in the city for good cars; we solicit the patronage of the public, relying on our ability to give good value; we have on hand Packards, Pope-Toledos, Rainiers, Panhards, Peerless, Franklins, Cadillacs, Stevens-Duryeas, De Leon, Pierce-Arrow, Richard-Brazier, Locomobiles, Fords, Autocars, Maxwells, Michigan, Reo, German Mercedes and others, International Automobile Exchange, 244-250 West 49th St., Phone, 2066 Bryant, New York City.

AUTOS CHEAP; great sacrifices; swell, reliable, standard makes in limousine, landaulette, touring, runabout styles; \$100,000 worth of the best automobiles possible at your price if within reason! 1907, 1906 models, touring or 4-cylinder runabouts; Renault landaulette, \$2,000 (cost \$7,000); Rochet-Schneider (\$7,500), \$2,500; Hotchkiss (\$11,000 town limousine), \$2,000; Packards, from \$950; 6-cylinder, \$4,500 Frayer-Miller, \$1,900; Locomobile (\$7,500), \$1,850; Buick, \$800; Panhards, cheap; Thomas 1906 Flyer, \$1,650; "Forty" Mercedes, \$3,000; Rambler, 4-cylinder, \$850; "Twenty" Locomobile, \$650; Autocars, wheel steer runabouts, \$450; Pierce-Arrows, 1906, way down; Cadillacs, Oldsmobiles, Maxwells, from \$100; 100 other unusual opportunities. Demonstrations cheerfully given; Manhattan's pioneer establishment; largest in America; greatest automobile cleaning up sale ever attempted. Broadway Mammoth Automobile Exchange, 247, 249 W. 47th St., 1780, 1782 Broadway, New York.

BUICK—1907, 4-cylinder, new touring car; used only as model, at small discount. W. Ricker, P. O. Box 146, Portland, Me.

CADILLAC—1905 runabout, with top; just fitted with three new tires; rear tires with Midgley tread; one extra casing; two extra inner tubes, two gas and two oil lamps. Prest-O-Lite gas tank; has never balked on the road, and has just been overhauled by competent men; run one year and half. Address Box U, Steubenville, Ohio.

CHADWICK 1907 cars are all sold. We want to clean up for 1908 business, and offer the following at prices which should sell them at once: 1906 Chadwick, 50-h.p. brand new; 1906 Chadwick, 50-h.p., refinished like new; both cars guaranteed one year; one Panhard 80-passenger wagonette; one 24-h.p. Locomobile. Chadwick Engineering Works, Spring Garden and 32d Sts., Philadelphia, Pa.

GET WISE—We have anything you want in second-hand cars—Packard, Winton, Locomobiles, White steamers, Franklins, Buicks, Oldsmobiles—and bargains at that. Get our list for March. The Sid Black Automobile Co., 630 Walnut St., Cincinnati, Ohio.

GREATEST BARGAINS in used automobiles ever offered in this country; 100 different styles. Tell us about what you want and we will send you descriptive matter. C. A. Coey & Co., 1424 Michigan Ave., Chicago, Ill.

HAYNES—40-h.p., Model K, 1906; I have two; \$1,850. Chas. E. Pelton, Lowville, New York.

MARMON MODEL D—1906; air-cooled; 30-h.p.; Rushmore lights, Sprague top, speedometer, 8 extra tires; machine just overhauled under owner's supervision; in excellent condition; price asked, \$2,000; cost \$3,300. E. H. Bancker, 92 Third St., Brooklyn, N. Y.

OLDSMOBILE—In fine shape; top and all accessories; \$225. Geo. S. Dales, Akron, Ohio.

PACKARDS, Reos, Cadillacs, Fords, Toledos, Maxwells, Locomobiles, Olds, Knox, Wayne, Franklin, Autocar, Pope-Hartfords, Yale, Peerless, Thomas, Buicks, Winton, Pierce, National and many others; every one a bargain and you get a square deal. The Starlin Company, 1094-1100 Main St., at St. Paul St., Buffalo, N. Y.

PEERLESS—Two 4-cylinder; one 4-cylinder Ford; all in first-class condition, having been thoroughly overhauled. A. Dussault Auto Works, Lockport, N. Y.

POPE-TOLEDO touring car; 1906; complete with top; in first-class condition; price, \$2,750. Address John H. Capstick, Boonton, N. J.

POPE-TOLEDO—35-h.p. touring car; good condition; side entrance; used two seasons; cost, new, \$4,000; price reasonable. N. N. Hill, East Hampton, Conn.

POPE-TOLEDO—1905, 35-h.p., for sale; has folding top, with storm curtains, French glass wind shield, Hartford suspensions, Gabriel horn and 8-day clock; tires in excellent shape; demonstration on request. Mr. Covell, Central Park West and 110th St., New York.

RAMBLER—16-h.p. touring car, good as new; '04 model, full equipped; \$450. F. W. Jackson, Holland, Mich.

RAMBLER TOURING CAR—Five-passenger, side entrance; complete equipment; \$600. L. J. Hansen, 32 East Main St., Massillon, Ohio.

RAMBLER TOURING CAR—Five-passenger; splendid condition; canopy top, glass front, and side baskets; \$500 cash. Speed Changing Pulley Co., Indianapolis, Ind.

ROYAL TOURIST—1906; gas and side lamps, speedometer, recently repainted; in first-class order. 724 E. & B. Bldg.; Rochester, N. Y.

SPECIAL OFFERS in desirable automobiles—Among the 250 cars now here the following have been consigned for quick sale: Corbin, 4-cylinder, splendid condition, top, lamps, etc., \$900; Peerless, like new, fully equipped, \$1,200; Aerocar, Prest-O-Lite gas tank, Gabriel horn, etc., \$1,350; Columbia, 4-cylinder, like new, fully equipped, \$1,500; Franklin, 6-cylinder, little used, \$1,700; Pope-Toledo, 4-cylinder, 30 to 35-h.p., leather top, lamps, etc., \$1,800; Panhard, 4-cylinder, \$850; Thomas, 50-h.p., top, \$1,250; Packard, like new, 4-cylinder, \$1,000; Winton, in elegant condition, \$550; Buick, top, etc., \$650; Locomobile, 4-cylinder, cape top, \$1,250; Pierce-Arrow runabout, \$300; Knox runabout, \$300; Decauville runabout, 4-cylinder, \$950. Over 250 others; runabouts \$125 up; tonneaus \$250 up; a number of electric and steamers at special sacrifice prices. Manhattan Storage Co., Largest Auto Dealers in the World, 334-340 West 44th St., two blocks from 42d St. station 9th Ave. "L"; three blocks from Broadway, New York.

STANLEY TOURING CAR—Model F, with top, gas lamps, Ecco generator, extra shoe and two tubes, trunk and rack; car just been overhauled and repainted; owner going west, and car must be sold at once. Rutland Machine & Automobile Co., Rutland, Vt.

STEVENS-DURYEA—1906; full equipment; cost nearly \$3,000; first-class condition; price, \$1,800. Box 478, Amsterdam, N. Y.

STEVENS-DURYEA—Model R, 1906 touring car; new Aug. 1; owner has bought 6-cylinder, same make. Box 1483, Springfield, Mass.

STEVENS-DURYEA—1906, Model R car, with or without top; car newly varnished; not run over 2,500 miles, and good as new; tires good condition; Never-Out gas lights, generator; owner wants 6-cylinder; first draft for \$1,750 gets car; a bargain. Staacke Bros., San Antonio, Tex.

STEVENS-DURYEA—Three second-hand, 2-cylinder runabouts, \$650 to \$900; three second-hand 4-cylinder Stevens-Duryea touring cars, \$1,500 to \$2,000; all these cars thor-

oughly overhauled by factory experts and are in first-class condition; they were taken in trade for new models. R. R. Kimball, 2026 Farnam St., Omaha, Neb.

WHITE STEAMER—1906 model, with 1906 burner, 1907 pumps, new thermostat; driven 4,000 miles; now being assembled after a thorough overhauling by the owner; if in the market for a White car, it will pay you to investigate further. H. W. Beach, Montrose, Pa.

WINTON, MODEL K—1906 Model, 30-h.p., like new; fully equipped; top; guaranteed perfect; to close quickly, price \$1,100. H. O. Koller, 26 S. Fifth St., Reading, Pa.

WINTON, MODEL M—1907, new 40-h.p., with top, lamps, etc., cost \$3,725, will sacrifice for \$8,000 cash; can inspect at Winton Garage, 70th and Broadway, or inquire C. Thorne, 30 Fine St., New York.

Parts and Accessories (FOR SALE)

ASTER MOTOR—24-30; suitable for automobile or launch; complete with transmission gear and clutch, La Coste coil, Lukenheimer oiler, Langmere carbureter, low-tension magneto, spark plugs, etc.; brand new, never run; cost, duty paid, \$2,300; will sell for \$1,300. Glasgow, 565 Washington St., Buffalo, N. Y.

AUTO TOPS from \$25 up; also recovering and repairing; prompt and satisfactory service and lowest prices guaranteed; a specialty of automobile upholstery. Paris Auto Top Co., 312 West 52d St., New York City. Phone, 6444 Columbus.

TIRES for automobiles; brand new goods; overstocked: 28x2 1-2, \$8; 28x3, \$14.50; 28x3 1-2, \$14.80; 30x3, \$14; 30x3 1-2, \$16.50; 30x4, \$18.75; 82x4, \$20; write for other sizes; will surprise you. A. H. Kaner, 152 Church St., New York. Largest Tire Dealers in U. S.

TIRES—Don't buy without getting our prices. We are closing out a stock of 2,000 standard clincher tires at half price. Guaranteed to be absolutely new and in per-

fect condition. Special discount to dealers. T. J. Peterson Co., General Offices, Security Building, Chicago, Ill.

TIRES—Second-hand tires and tubes all ways on hand; vulcanizing in all its branches; recovering a specialty; leather non-skid tires recovered and warranted to run 2,000 miles; write for price list of repair work. N. Y. Steam Rubber Tire Repair Works, 306 West 52d St., New York. Phone, 3018 Columbus.

Parts and Accessories (WANTED)

AUTOMOBILE TURNING and chucking machine wanted at once; Potter & Johnson 8 1-2"x16"; second-hand machine in good condition acceptable. Communicate with American & British Mfg. Co., Bridgeport, Conn.

Situations Wanted

AUTOMOBILE ENGINEER — Over ten years' experience with some of the largest manufacturers in the country; several years in present position; capable, economical and energetic; can take full management of whole plant or any department, and can straighten out or build up any industry; good systems; best of references. Address XXX, care The Automobile.

BRANCH MANAGER wants position as branch manager, salesman or factory representative; have had seven years' practical experience in one of the largest automobile factories, and recently manager of a large agency; my personal sales exceeded \$400,000 last season; open for a proposition for '08 contract. Address "Sales Manager," care The Automobile.

CHAUFFEUR—Would like a position in private family; do own repairing; strictly temperate; American. E. C. K., care The Automobile.

EXPERT MACHINIST-CHAUFFEUR open for engagement July first; 34; habits and character of the best; capable of holding, and will accept only first-class position. D. C. Thorp, 478 West 145th St., New York City.

MANAGER, SALESMAN and publicist by man of 20 years' experience in every department of the Metropolitan carriage business; at present well connected, but as high as place will permit; can make good. Fidebus, care The Automobile.

Help Wanted

FACTORY MANAGER—For a large, high-class automobile factory; must have a good mechanical and business education. Address Manager, care The Automobile.

REPAIR MAN—To take charge of shop; must be first-class; give references; state salary. M. F. Hickman, Afton House, Washington, D. C.

Insurance

INSURANCE for motor cars against every risk, including fire, explosion, self-ignition, theft, collision, accident, transportation, perils and other damage; cars insured anywhere in the world by the kind of "Policies that Protect," at the lowest rates of premiums; automobile ball bonds to cover all States. Dixie Hines, Times Building, New York City.

INSURANCE for automobiles—Broad, safe policies at lowest prices; insurance against fire, self-ignited explosions, transportation hazards, theft, etc.; best service guaranteed, no matter where insurer is located. For particulars address H. W. Beals, 76 Williams St., New York City. Phone, 3052 John.

Miscellaneous

AUTO BUSINESS—Well established; for sale, owing to ill health; 25 miles from New York. Auto Business, care The Automobile.

CONTROLLING SYSTEM—We are now putting on the 1903-'04-'05 and '06 White steamers a controlling system we have just perfected that will keep the steam pressure from five to six hundred pounds, under all conditions of the road; any car having our controlling system can equal the 1907 White steamer now out; not only equal, but better them. We also are makers of flash boilers, in any style or size. For further information, write Wilson Austin Auto Co., Minneapolis, Minn.

DRAFTSMAN—Thorough and complete course of instruction in automobile design and construction prepared and conducted by E. Favery. Fundamental elements of design; formulæ; applications; latest practice of American and European builders. Information impossible to obtain elsewhere; of greatest benefit to designers, draftsmen, engineers, salesmen and others desiring thorough knowledge of automobile design and construction. Instruction in class room or by mail. Prospectus on request. New York School of Automobile Engineers, 146 West 56th St., New York.

GARAGE FOR SALE—Whole or part interest in best located and finest equipped garage and repair station in Buffalo. Address Garage, Gen. Delivery, Buffalo, N. Y.

GARAGE FOR SALE—Or partner wanted; garage without doubt the finest in all Indiana; four agencies and thirty regular boarders; \$4,000 required. C. A. C., care The Automobile.

MACHINERY WANTED—To use in auto mfg. H. Russell, P. O. Box 146, Portland, Me.

TIRES REPAIRED—Automobile owners, do you want your tires repaired or recovered by people who know how? Give us a trial, and be convinced. Inner tubes vulcanized at short notice. Jungking & Vogler, 158 Chambers St., New York City. Telephone, 3386 Cortlandt.

Economy, Efficiency and Safety

THE NATIONAL Gasoline Storage System
 is the most economical, because it entirely
 eliminates evaporation and waste of gasoline.
 It is the most efficient because the NATIONAL
 Pump discharges gasoline at every movement
 of the crank, and is always ready to operate.
 It is the safest, because it meets ALL of the
 requirements of The National Board of Fire
 Underwriters. Ask for Catalogue.

The NATIONAL OIL PUMP & TANK CO., Dayton, Ohio

Motors and Motoring

By HENRY J. SPOONER, C. E.

This is undoubtedly the best book for the owner or intending purchaser who desires to get a good practical idea of the how and why of automobile construction and operation without having to read a great mass of highly technical literature. It is written in a simple condensed style and the text is well illustrated by diagrams. A work vastly superior to the numerous cheap and inaccurate compilations on the market.

In cloth covers, 103 pages, 5 x 7 ins.

Price one dollar, postpaid

Wetherbee Storage Batteries

in the Sealed Bonnet Contest

68% of all the Storage Batteries used were Wetherbees—17 out of 25 cars using Storage Batteries used Wetherbees. Our next nearest competitor was represented on four cars only.

The fact that in a contest of this character, where reliability and long lived efficiency were essential, so many used Wetherbee Storage Batteries, is proof of the esteem in which they are held by the owners and manufacturers of high grade automobiles.

Where there is a question of endurance you will find that all the *wise ones* use *Wetherbees*. The battery that looks good—is made better than it looks—*made good* all the way through.

There must be a reason—**QUALITY.**

Reasons Why

THE

Bougie Mercedes
1909

See the new
Detachable
Connection

Is the BEST Spark Plug

- Reason No. 1:** It is absolutely Proof against Oil and Soot.
 - Reason No. 2:** It is absolutely self-cleaning.
 - Reason No. 3:** It has an insulation of double stone, guaranteed *never* to crack.
 - Reason No. 4:** It's the fastest plug made.
 - Reason No. 5:** It has no packing in the heat.
 - Reason No. 6:** It is the only plug suitable for high tension ignition.
 - Reason No. 7:** We guarantee it for one year and recommend it where all other plugs fail.
- Two Hemispheres acknowledge The Bougie Mercedes to be the Best and Most Reliable Plug ever made.

WISDOM

IS NEEDED TO SELECT A TIRE.

There are many inferior makes, tremen-
dously advertised.

DON'T GET HUMBUGGED!

PROTECTOR OF
HALF VULCANIZED
RUBBER

NOTE THAT EVERY STEEL
STUD IS COVERED WITH
A RUBBER-COATED SLEEVE
AND RUNS THROUGH TWO
LAYERS OF RUBBER AND
ONE STRONG LAYER OF
FABRIC

A FACT:

There is no tire on the market that
is giving permanent satisfaction ex-
cept the

HERZ TIRE

a product of personal skill and en-
deavor piece by piece.

The Herz Tire is made in Austria
from the purest and best Para Gum,
which is almost indestructible. It is
impossible to injure it mechanically

One Herz Tire will outlast 3 of
the other makes. Buy one and com-
pare the effect of its wear with your
three other tires. You will find the
Herz Tire will look like new while the
others will be worn to shreds. Our
reputation on 2 hemispheres stands
solidly behind the Herz Tire.

The Herz Tire is the highest priced
European tire made. Still we sell
it at a lower price than any other
imported Tire.

It's a case of directness: From
Importer to User.

Write us about the Herz Tire and
let us tell you its story more thor-
oughly and more interestingly.

Sent free to all garages and auto owners.

Write for it to-day.

Manhattan Storage Co., 42 Cortlandt Street N. Y. City

Before You Start

on your next trip be sure that your gasoline tank is fitted with a

"Triumph" Tank Gage

enabling you to tell at a glance if the tank contains enough fuel to carry you to your destination. Get rid of taking off the filling cap and sounding the tank with a stick. The drip from the stick is as bad as powder. See that your new car is equipped with a "Triumph" Gage, thus avoiding bother, save chauffeur's time, and save money in your gasoline bills.

Boston Auto Gage Company
 4 Old South Building, BOSTON, MASS.

Long Manufacturing Co.
CHICAGO, ILL.

LONG DISTANCE

Get our new catalogue for 1907 and 1908 before placing your orders for HOODS, FENDERS, DASHES and RADIA-TORS

THE WATER WAY
BETWEEN
BUFFALO AND DETROIT

The D. & B. Line Steamers leave Buffalo daily at 5:30 p.m., (eastern time) and Detroit week days at 5:00 p.m., Sundays at 4:00 p.m. (central time) reaching their destination the next morning. Direct connections with early morning trains. Lowest rates and superior service to all ports west.

Rail Tickets Available on Steamers
All classes of tickets sold reading via Michigan Central, Wabash and Grand Trunk Railways between Buffalo and Detroit, in either direction will be accepted for transportation on D. & B. Line Steamers.

Send two cent stamp for illustrated pamphlet. Address, L. G. Lewis, G. P. & T. A. **Detroit & Buffalo Steamboat Co. DETROIT, MICH.**

WINCHESTER SPEEDODOMETER

"A Fine Instrument for a Fine Car."
Send for Catalog J
1557 Broadway, New York

ABRAND NEW AUTO OILER

This Oiler is made entirely of brass, also of cop-perized steel with brass trimmings. Has strainer and double valves. The spout is detachable for packing in small space. A pressure on the plunger forces the oil to the bearings—avoids the pleasure (?) of crawling under the car.
At all Supply Houses. Brass sample prepaid \$1.75

The Complete Motorist

No theory, but all about an automobile—its history; its mechanism and how to select and run it. By A. B. FILSON YOUNG. 328 pages profusely illustrated Bound in cloth. Price, \$3.50. Address The Automobile, Flatiron Building, New York

HOLSMAN

FIVE YEARS OF SUCCESS.

The Holsman automobile has now been on the market five years and has long since passed the experimental stage. It is built high enough to travel the country roads like a carriage and can be run twelve months in the year. It clears the centre of the road by eighteen inches, and therefore has **twice the advantage** of the ordinary machine in muddy, rutty, rough or rocky roads. Has large wheels, solid rubber tires and **rides like a carriage.** The Holsman exclusive patent marks an era in automobile building. It does away with all live axles, friction clutches, differential gears, pumps, etc. Reverses without extra gears. **No water to freeze. No puncture troubles. No odor. New hill climbing power.**

The Holsman Automobile Co.
Room 601, Menashaek Block, CHICAGO

ESSENTIAL FEATURES of CRANK SHAFTS

In addition to correctness of design, quality of material and accuracy of finish are essential features. If you are having crank shaft troubles, it is probably on account of defective or unsuitable material, or imperfect finish or both. It is as important that they be properly made, and from good material, as it is necessary to prepare the design and dimensions. If you will furnish the specifications, we will undertake the rest. We make them to order only, finished ready for use. We want your orders, and can convince you that we merit them.

Send complete specifications for prices.

Rest Your Tires
When your car is not in use. Relieve them of the weight of the car and get them off dirty, oily floors. It is all so easily and quickly done with the **SPRINGFIELD LIFT**

Can be used under any car. Price, \$10.00 net.
The Shawver Company, Springfield, Ohio

HAM'S VIGILANT TAIL AND INSPECTOR LAMP

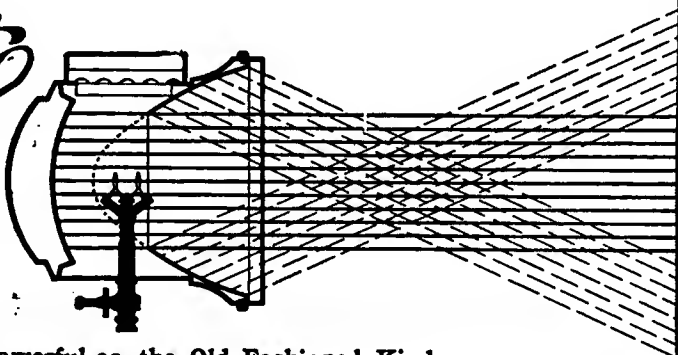

A Tail Lamp That Will Stay Lit
It is very humiliating to have to appear in court for driving without your tail lamp lit, and it's really not your fault, as you are sure you lit it just a few minutes before; but it's the old story—the lamp is not built right, and just as soon as you start your machine it dies down and goes out, and one fine would more than pay for the best tail lamp made.
Ham's is the best. It's built on our genuine "Cold Blast" principle and is guaranteed not to blow or jar out. Beside the red light it gives a powerful white light, and the side handle makes it very convenient to use for inspecting engine or car in case of a breakdown. It is fitted with our new safety handle.

Ham's NEW SAFETY Bracket.
This will be appreciated by all who see it.
With our new Safety Locking Handle and Bracket you do away with the constant annoyance of losing your lamp or having it stolen.

HAM'S SAFETY BRACKET.

Our Auto Booklet will interest you—write to-day. Address Dept. "B"

AVOID ACCIDENTS

BY USING THE

SAFETY STEERING DEVICE

STEERING DEVICE
B 93

Mr. Automobilist, did you ever stop to consider how much really depended on your steering device? The safety of your car and its passengers hinges on the reliability of its steering mechanism. A bursted tire on high speed is considered dangerous, but not serious to control. If your steering device goes wrong or does not respond instantly, the most skillful driver becomes absolutely helpless. Four essential features are embodied in the construction of the Safety Steering Device, viz.: Safety, Durability, Compactness and Weight.

Safety is positively secured by the worm and sector construction, which has stood the severest test known. The drive is worm gear. The worm and sector is made of the best quality steel and case hardened 1-3/4 inch deep, and teeth bearing ground, thereby eliminating at least one year's wear over gears not ground, thereby making one of the easiest operating steering gears made. All working parts are enclosed. This device can be easily attached, and we are daily making replacements on many of the leading cars. Several large manufacturers have been using our device for the past three years. Write for testimonial letters from users and full particulars to-day.

The WILLET CARBURETER PAR EXCELLENCE

THE CARBURETER
for Low Grade Gasoline
for Two or Four Cycle
Engines

Easiest Starting Carbureter in the world

A Carbureter you can depend upon—that always gives a perfect mixture regardless of conditions imposed

The superiority of the Willet Carbureter is that instead of a single nozzle there are a series of six small tubes which form individual nozzles fed from the inlet at the bottom. Owing to restricted openings, the air must pass close to the points of the individual nozzles and carry a considerable quantity of gasoline even at slow speeds. A conical shaped valve makes the carbureter very sensitive, and the concentration of air over the individual nozzles gives such a good mixture that the engine can be readily started. Write for full description and prices

Model B
4x4 40 H.P. Air Cooled

Reeves Pulley Co., COLUMBUS INDIANA

FORCES THE OIL ANYWHERE. It delivers thick or thin oil, a drop or a tablespoonful at a time according to the pressure of the thumb on the piston. The flow of oil is perfectly controllable at all times, whether the spout is directed upwards or downwards. A slight pressure of the thumb delivers the oil in drops. A heavier pressure throws an even stream until the entire contents of the can is exhausted.

With The "CANNON" Force Feed Oiler there is no waste, the oil goes just where it is needed and nowhere else. No need to wipe up with a piece of waste afterwards.

For hardness, convenience and economy YOU need a Cannon Force Feed Oiler. Ask the supply man for a "Cannon" today. He has a supply or ought to. If he hasn't write me direct.

Lavigne Oilers Assure Perfect Lubrication for Automobile and Motor Boat

"The proof of the pudding is in the eating thereof."

The following letter needs no further comment
Detroit, Mich., Sept. 26, 1906.

Lavigne Mfg. Co.,
Detroit, Mich.

Gentlemen:
Enclosed find my check in payment for the force feed oiler which I have just installed in my launch and find very satisfactory.

I want also to add that the one I have had on my automobile the past year has been most satisfactory, too, and amply repaid me for its substitution in place of the exhaust pressure feed oiler that I had on the machine. Very truly,
WALTER S. RUSSEL,
(Russel Wheel & Foundry Co.)

Specify the Lavigne Oiler on your car or boat and you will make no mistake

\$1.40 PREPAID TO ANY ADDRESS IN THE U. S.

GIVE A CARE to your gasoline pipe strainer, as nine times out of ten it is the secret of carburetor troubles. A little water or foreign substance in the gasoline will put your carburetor out of commission. Our strainer is a guarantee against such troubles. It is made from sheet brass, highly polished, and furnished with either 1/4 or 5/16 inch connections. The gasoline enters through the low connection, strains through a chamois placed at an angle across the globe, and passes to the carburetor through the upper connection cleansing the gasoline thoroughly. The foreign substance remains beneath the chamois and may be drained through the petcock. Write to-day for catalog. Special prices to manufacturers and dealers in quantities.

16 East 42d Street New York, N. Y.

The Why of the Duplex Coil

Two cores instead of one means short primary and secondary windings—no loss of energy in the coils—the full voltage being delivered to the

vibrator. They mean 4-times-greater magnetic force—the use of a strong spring and light armature, a quick, hot spark at that point of compression which produces *full force and power*.

"A mile's trial will prove it all." Therefore we make the following offer to you to-day. Don't doubt. Just write.

30 Days' Free Trial

We will send the Duplex Coil, express prepaid, to any manufacturer or respectable automobile owner on its merits. Put this coil on any car in place of any other coil on the market, and if, after a reasonable trial, the Duplex Coil does not show greater efficiency, does not give a hotter spark, does not increase the power of your car, does not use less current for a given mileage and is not more generally satisfactory than any coil on the market, remove it from the car and return it to us at our expense, and the test will have cost you nothing.

If the coil bears out our claims, after a most rigorous trial, then pay us the small sum which we ask.

Write us to-day as your business stationery and a Duplex Coil will be sent you at once.

"Leavitt" 1907 Specialties

The Leavitt Secondary Distributor and Spark Timer has been on the market for the past three years and has more than proved our claims of "Simplicity, Reliability and Efficiency." It has been tested out in the experimental departments of the leading manufacturers and the proof of its having won out is in its being adopted by a number of the leading manufacturers on their '08 cars in connection with the Magneto System. Hadn't you better investigate?

"COMPLETE IN ITSELF"

Decide today to have an ignition system on your car that never runs out of current--in which the current is always a uniform voltage --and which will last as long as your car. In short decide on an

Apple Ignition System

"Floating the Battery on the Line"

It provides a charging outfit right aboard your car, complete in itself. The dynamo, run by the fly wheel of your engine, charges the battery, and keeps it always full of current of even voltage, of a quality ideal for ignition and lighting work. No limit to the distance you can travel with it. Send in your request at once for our Bulletin B-1.

The Royal "Multiplex" Lamp & Attachment
(Patents Pending.)

**SOME
FACTS**

Nine times out of ten an owner has a Storage battery, a Dynamo or a Magneto.

Now then, why should he carry around with him a cumbersome gas tank, or an explosive generator if he can light his lamps with our "MULTIPLEX" LAMP, on his Battery, Dynamo or Magneto?

The "Multiplex" Lamp gives 30 to 32 candle-powers with reflector on 6 volts. It will burn from 300 to 400 hours and will give a blinding, dazzling light.

No storm can blow it out. No matches needed. No leaky hoses to cause trouble. Light your lamp from the seat.

Tools needed to install: a screwdriver--that's all. We have now 4, 6, 8, 10 and 12 volt lamps in stock for immediate shipment. Renewed bulbs, any voltage up to 12, \$1.25. Complete outfit--1 Bulb, Attachment, 10 foot cable, Snap Switch and directions, \$2.50 (By mail \$2.60).

Double outfits for 2 searchlights or 2 headlights, \$5.00 (By mail \$5.20). Ask any Automobile Supply Store or Garage to get it for you, or we will send it by mail.

HARRIS OILS

TRADE MARK REGISTERED

A. W. H. Gas Engine Cylinder Oil.

Medium bodied, a suitable oil for the majority of water cooled motors.

Will not carbonize in the cylinder.

Sold at all principal garages.

A. W. Harris Oil Co., 330 S. Water St. Providence, R.I.

THE SWING OF THE PENDULUM

Not only the confirmed imitator at home, who would be copying something else if he were not copying the Rushmore, but the European lamp maker as well, feels strangely drawn Rushmoreward this year. It's a piquant fact that while the American copyist was reproducing the foreign reflector lamp last season, the foreigner was getting ready to copy the Rushmore!

But the RUSHMORE LENS MIRROR is as far from being duplicated as ever, and Rushmore solidity of build is still unique.

HAS CARRIED THE
"CHINESE COPYIST"
TO THE
RUSHMORE
PATTERN
THIS YEAR

WHAT THEY SAY OF THE

RUSHMORE SHAKING GRATE GENERATOR

(AND THE RUSHMORE SEARCHLIGHT.)

No. 4

THE RUSHMORE DYNAMO WORKS,
Plainfield, N. J.

Gentlemen: You hardly need to write me in the interest of the Rushmore lens for automobiles. I have a 9-inch searchlight on my Winton, and an 8-inch on my Franklin, and one of the new GENERATORS on each car. There is no other lamp comparable with them, and the new GENERATOR deserves all praise. All the same, I should be pleased to receive a catalog.

INDIANAPOLIS, IND.

E. F. HODGES, M.D.

P. S. Mr. Carl Fisher has had the upbringing of this particular automobilist, and while he cannot always have his way with purchasers, in my case he could—and knew it—and would listen to no suggestions as to other lamps but simply insisted that the Rushmore was to all others as gold to copper. He had his way and I am glad of it.

E. F. H.

No. 5

RUSHMORE DYNAMO WORKS,
Plainfield, N. J.

Gentlemen: Enclosed find check for GENERATOR as per your quotation of February 6. While I have had this GENERATOR for some time I have only used it about ten days, and I find it far and away more satisfactory than the one I was, and am still, using on one of the two lights.

GEORGE W. YERKS & CO.

ALBANY, N. Y.

MATHEW VAN ALSTYNE.

No. 6

RUSHMORE DYNAMO WORKS,
Plainfield, N. J.

Dear Sirs Thanks for yours of May 7th. I know just how my "Packard 24" would look with your lamps and GENERATOR, because I have them, and would be content with no others, having used your lamps for the past three seasons. This is the first year for the GENERATOR, which has done very well so far.

OVERBROOK, PA.

CLYDE A. HILLER.

The Rushmore Generator is not a cheap makeshift, but a fully developed automatic device. When handled according to instructions, it gives a perfectly uniform gas supply with none of the annoyances common to the ordinary types of generator. Our catalog describes it in detail.

Rushmore Dynamo Works, Plainfield, N. J.
LONDON PARIS CHICAGO

AN INVALUABLE FEATURE OF "BREECH-BLOCK" PLUGS

IS THE BREECH-BLOCK WHICH ENABLES THE OPERATOR TO OPEN AND CLEAN THE PLUG IN 4 SECONDS

INSTANT REMOVAL AND REPLACEMENT WITHOUT TOOLS.

NO OTHER PLUG IN THE WORLD HAS THESE ADVANTAGES.

Soot-proof to the limit. Unaffected by oil. Chambered end protects porcelain. Keeps porcelain fragments from cylinder. Slightest piston movement cleans points. Makes starting easy; fires first charge. Closely throttled; not a skip. Better value than any other plug made.

This plug is enthusiastically recommended by such experts as Barney Oldfield and thousands of users all over the country.

We guarantee better results with the Breech-block than any plug made. Write for full particulars and prices.

THE STANDARD CO.
TORRINGTON, CONN.

Cleaning Without Scratching

There are plenty of "cleaners" that take off the mud, but all the fine polish comes off with it. The right way to clean the automobile body of mud, dirt, grease and grime and still leave the paint and varnish there—is to use

MOBO

Automobile Cleanser

It is purely a vegetable compound. As smooth as velvet to the touch and won't injure the most sensitive bands. Mobo brings back the lustre to the dullest car, protects the highly polished surface, and prevents blistering and cracking.

Put up in 3-lb. and 6-lb. cans; likewise in tubs, half-barrels and barrels. The following house sells it:

MOTT & SMITH
Far Rockaway, Long Island, N. Y.

and at all good automobile supply stores in all leading cities.

Send for free Mobo booklet—"How to Clean Well Varnish and Paint on an Automobile."

JOHN T. STANLEY
640 W. 30th St., New York

CORNELL GARAGE

PORTABLE

The Solution of the Automobile Garage Problem

The high cost of stabling entirely eliminated by keeping your car in your own garage—a "CORNELL GARAGE"—which is built in style of architecture and color to match your residence, of "CORNELL GARAGE" interchangeable sections. Can be erected by any ordinary help on day of delivery, without nail or screw. Your car is always convenient, safe from unauthorized use and the destructive odors of public garages.

This "ready-made" adequate protection, right at home, within immediate reach, the housing of your car becomes a pleasure instead of an expensive luxury.

Regular styles at moderate prices ready for immediate shipment.

Special designs and specifications submitted and orders executed promptly.

WE ALSO MAKE

Portable camps, cottages, play houses, etc.

HEINZE ELECTRIC COMPANY, - Lowell, Mass.

"It's nice to know how far you go; and this will show, the speed—also."

Veeder TACHODOMETER

The Scientists' Speed Indicator applied to automobiles. Registers how far—total and for each trip—and shows exact speed at all times from zero to 62 miles per hour.

No springs nor variable elements.

No delicate mechanism.

Only one moving part.

The only speed indicator that can be accurately set to zero at any time by the owner.

The Veeder Tachodometer, a Tachometer and Odometer combined, is unquestionably the most accurate instrument for indicating speed. Used in the greatest laboratories and shops; time tried, reliable and now fitted for automobile use.

Of the many principles on which speed indicators may be designed, we have chosen the liquid centrifugal, for, having found the means to overcome the early difficulties of using a liquid, the results are so satisfactory and so positively accurate that this system rises superior to all others.

One shaft with paddle wheel permanently attached forms the single moving part, and all operations are based on the natural laws of gravity and centrifugal force. Until these laws change the Veeder Tachodometer must remain permanently accurate.

It is practically impossible to wear it out.

Neither time, use, friction, nor temperature can change its absolutely accurate readings. Any instrument in which springs are employed (and practically all other speed indicators contain springs) vary with age, temperature, and especially with the friction of moving parts, and only by special lubrication, not found in the ones you buy, can correct readings be obtained for even a short time. The Veeder Indicator does not wobble nor swing about, but follows exactly every slightest variation of speed; can be placed

PRICE, COMPLETE, READY TO GO ON ANY CAR. \$75.00

on the dash or in the tonneau or limousine, and is read from a distance at a glance. Supplied with attaching fixtures for all makes of automobiles. In ordering state make and model of car, also year of manufacture.

THE VEEDER MFG. CO.

22 SARGEANT STREET,

HARTFORD, CONN.

Manufacturers of Cyclometers, Odometers, Tachometers, Tachodometers, Counters and Fine Castings.

Made Good—Makes Good

“Made good” in the shop, it has “made good” on the road, and therefore with its owners.

No greater correctness of principle, no better working out of design, no more thoroughness of construction, no finer quality of material, no more simplicity and reliability could be put into a car.

Simple — Strong — Powerful — Reliable

The DRAGON is a car for the owner, not the repair man. It sells easily on talking points that stand up as plain as a post when you look into it. When a prospective customer looks, he generally buys.

Two Models — Touring Car and Roadster — 24-26 h.p.

Stewart Speedometer

Our Five Year Absolute Guarantee

WE guarantee each Stewart Speedometer against everything but misuse for a period of five years from date of purchase. This guarantee and warrant covers materials, mechanical construction and accurate operation of the instrument, flexible shaft and all connections. Each instrument is calibrated tested and sealed before leaving the factory. Any instrument returned to us, at our factory, charges prepaid, with seal unbroken, that has failed to give proper service, or failed to register accurately, or which has otherwise proved defective in material or construction, within above mentioned term, will be repaired or replaced free of charge.

\$40.

We can make immediate shipments on 50 and 60 mile instruments

We are told our new catalogue, just issued, is the handsomest and most comprehensive book on speedometers yet published. It illustrates and describes the interior mechanism so that all may know why the "Stewart" is sought by those experienced in speedometer matters. Copy for the asking

Save 27 Minutes

The usual time required to replace a punctured tire is 30 minutes.

With the

CRESCENT

(Formerly Harburg)

Removable Rim

a complete tire change is made in 3 minutes, by the watch.

The above sectional view shows the permanent beveled band, fitted to the wheel felloe, the adjustable rim holding any regular make of clincher tire, and the hinged clip, six of which are used to hold the rim in place.

Extra tires and rims are always carried—the tire being inflated at home before starting on a trip.

When a puncture is experienced, the damaged tire with its rim is removed and the extra rim and inflated tire is quickly bolted to the wheel, the entire operation consuming but three minutes.

Nothing could be more simple. Irritating delays are absolutely done away with. All parts are galvanized, nicked or bronzed, thereby preventing any possibility of their rusting tight.

Any regular make of clincher tires fits these rims. Can be used on old or new wheels.

Write to-day for particulars, prices and descriptive circular.

The Crescent Parts Co.

Dept. A. 1743 Broadway
NEW YORK CITY

SIMPLICITY

Is the keynote of the Holley 1908 Carburetor and High Tension Magneto

And it is genuine simplicity, too—the kind of simplicity that makes for added efficiency; not the imitation variety, which is gained at the sacrifice of perfect performance.

Side Outlet Model

(Top Outlet also furnished)
(Patents Applied For)

THE HOLLEY 1908 CARBURETOR

is unique among its kind—an Automatic Carburetor Without Moving Parts. There are no springs to change their tension, no valves to stick, only one adjustment—that of the needle valve controlling the spray. Automatic action is produced by the shape of the mixing chamber and the arrangement of the spray orifice, and the veriest novice can get as good results as the most expert.

(Patents Applied For)

THE HOLLEY HIGH TENSION MAGNETO

affords a dual ignition system so simple, so adaptable, so "common-sensical" that no owner of a four or six-cylinder car can afford to be without it. It gives two sources of ignition—magneto and battery—entirely independent, yet operating through the same coil, timer, distributor and plugs; and either can be removed in a moment, leaving the other undisturbed to run the car. It gets rid of practically all the additional complication and expense of the ordinary dual ignition systems.

Holley Brothers Company
DETROIT, MICHIGAN

On Your Machine—Not On Your Mind

After all, the tire question, provided it has been wisely disposed of at the outset, is a mere incidental one. It assumes an undue prominence only when this precaution has been omitted. Many good things might be truthfully said about

G & J TIRES

but they are all summed up in this:—that when your machine is equipped with them you can dismiss the tire question for good. In case of accident quick and permanent repairs insure an immediate return to the *status quo*.

The Midgley Universal Rim can be used interchangeably for the Dunlop or clincher type. It's no trick at all to take the tire off when you want to.

Does not *stick, crack, break, gum, rot or peel*. Free from oil, gum, rubber or disagreeable odors.

For Automobiling, Yachting, Hunting, Fishing, Railroading and General Use

Lasts longer, and gives greater protection and comfort than any other kind of storm clothing. We supply *Jackets, Overalls, Hats, Coats, Military Capes, Pants, Leggings*—outfits for every need. Raino garments are well made, natty, right up-to-date in style.

Write for Free Book telling all about Raino Waterproof Clothing and how the soldiers in the United States and Philippines are buying RAINOS out of their little \$13.00 a month to take the place of rubber ponchos and oilskins furnished free by the government. Also letters from prominent yachtsmen, hunters, automobilists, etc. You can try RAINO CLOTHING 30 days, and if not satisfactory we refund full amount paid. Write to-day for book and Free Samples. **WE PAY EXPRESS CHARGES IN U. S.**

THE RAINO CO., 785-765 SOUTH HALSTED STREET, CHICAGO, U. S. A.

Construction of a Gasoline Motor Vehicle

By C. C. BRAMWELL. Contains 150 pages, 6x9; one hundred illustrations and diagrams. Publisher's price, \$2.00; our price 80 cents. Address, Book Department, The Automobile, Flatiron Building, New York.

A Cross Country Trip's The Thing—

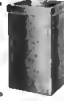

provided you are prepared for it. A good fat purse, and good company, and a good car are fine helps to an enjoyable trip; but if you want to reduce the contents of your purse to its lowest common denominator and cause your friends to admire you as cordially as the Czar admires the Douma, and cause your car to give you an imitation of down-country street car service, just specify tires for your trip that are not made for off-the-boulevard use.

MORGAN & WRIGHT TIRES ARE GOOD TIRES

anywhere, but the users who "root" the loudest for them are the ones who have tested them out on tours of from three to ten thousand miles. We do not claim that every tire will go thru an entire trip without trouble (accidents or careless driving make such a record impossible), but it would surprise some tourists to know what a large percentage of them will do it.

WE MANUFACTURE A FULL LINE OF BATTERY JARS AND ACCESSORIES OF A HIGH QUALITY. SEND SPECIFICATIONS AND GET OUR QUOTATIONS.

The Midgley Universal Rim accommodates either Clincher or Dunlop tires with the same set of beads, besides being as safe as a one-piece rim.

OTHER
MAKES

CENTRAL PENNSYLVANIA AUTOMOBILE COMPANY
GENERAL AGENTS FOR CENTRAL PENNSYLVANIA
 HIGH GRADE CARS, ELECTRIC, GASOLINE AND STEAM

HARRISBURG, PA., MAY 17, 1907.

Gentlemen:—In our recent Endurance Run, pulled off under the most trying circumstances, the roads being notoriously bad, and the weather worse if possible, we had on the White Steamer, Car No. 6, a valuable demonstration of the advantages of the Q. R. Rims. The time required in repairing our first puncture was not measured accurately, but we repaired the second one, and were again in the race, after four minutes. We next found a ten-penny wire nail driven in clear to the head. In this case, we took the tire off, put in a new tube, inflated it with the air pump of the car, in three minutes by the observer's watch, which we believe was "going some" in this line of work. *Our less fortunate competitors were, in many cases, three times that long in doing the same work.* Some cars in this run suffered as many as eight punctures and blow-outs, which accounts for the many bad scores shown on the Official record, and we considered ourselves fortunate in having Goodrich Q. D. tires.

Yours respectfully,

CENTRAL PA. AUTOMOBILING CO.
 I. W. DILL.

I. W. D.—M. M. T.

THE B. F. GOODRICH COMPANY, - Akron, Ohio, U. S. A.

THE TRIDENT RIM

A New Comer

for your approval, takes any Clincher Tire. When using Trident Tires can be easily removed from the rim without deflating tire.

Manufactured in Standard Clincher Rim sizes and profiles.

Commands your attention as being the only Side Ring Detachable Rim made that presents its auxiliary of removing tire without deflating same.

Manufactured exclusively for the Trident Tire Company, New York, by

"Keep Your Eye On Continentals!"

Continental TIRES

Sweeping Victory in the Herkomer Race

Once more the Continental Tire captures all the prizes at a great international automobile contest.

The 1907 annual struggle for the Herkomer Trophy was a magnificent race.

Automobiles were entered from practically every country in Europe. The route covered over a thousand miles, and passed through crowded cities, along the highways of the open country, and up and down precipitous and difficult mountain roads. There was a terrific strain on the tires as well as on the cars.

Continental Tires won the first seven positions, a showing never before equaled by any one tire in the history of automobiling.

The Herkomer race simply confirms our repeated statements---that for racing as well as for touring and town usage there is no tire made that can compete with the Continental.

I WILL PROVE TO YOU that

SULLIVANOIL

IS THE BEST CYLINDER OIL
ONE GALLON FREE

I have found that when a person begins to investigate the oil question, he generally arrives at the conclusion that a thick, heavy oil which has a great deal of "body" or density is the oil of merit.

This isn't true. A dense, heavy oil is slow acting, difficult to feed properly, and even mechanical oilers cannot deliver it in proper quantity at the proper place.

The other extreme—an oil too thin—must be used so freely as to flood the cylinders and even then the result is unsatisfactory for it hasn't body enough to lubricate properly.

There is practically as much residue (carbon) from the one as from the other in the regular cylinder lubricating oils on the market.

Now, after years of experimenting, I have discovered an oil of just the proper density, which lubricates any internal combustion cylinder perfectly and leaves no carbon. There is no residue left after combustion. The particular density or "body" of Sullivanoil is one reason why Sullivanoil is pre-eminently the best of all cylinder oils.

Sullivanoil is of hut one grade or density, and you do not have to buy three or four grades to experiment with to find the one grade that is best for your motor.

In Sullivanoil, I have a lubricant that has proven successful on all standard makes of cars.

Sullivanoil of one grade—the proper density—the right "body"—has proven satisfactory in every case.

Talk—promises—arguments are all right in their places—but—

I will prove to you by actual demonstrations that Sullivanoil is really what I say, the best cylinder oil for your motor.

I will do it entirely at my expense.

One Gallon Free

I will give you one gallon can of Sullivanoil free—no delivery charges—no obligation whatever on you—to try on your car.

Simply tell me that you own an automobile and send me the name of your dealer and I will have him deliver to you one gallon of Sullivanoil free of all charges.

Send for booklet "How to Test Oil," which gives many facts about oil that you should know.

Write me personally.

Ferro-VANADIUM

We call Vanadium the alloy that makes "Anti-Fatigue" steel because it produces a steel that doesn't get tired under the stress of constant service.

There are plenty of steels that will carry a heavy load and that will show up well under the ordinary tests for tensile or elastic strength, but they will not meet modern conditions in actual use. A sudden shock or unexpected stress is apt to crack them. They deteriorate and go to pieces under vibration. They are all right under ordinary static conditions, but they do not meet the dynamic demands of modern engineering.

Vanadium steel not only excels the other alloy steels greatly in elastic strength, but it is vastly superior in resistance to deterioration vibration. It is practically unbreakable either under a steady load or under constantly repeated shocks or stresses.

It can readily be understood what a steel of this character means in railroad or steamship equipment—in automobile construction or in any place where *the safety of human life depends upon the material used.*

Vanadium steel is now being manufactured and extensively applied to these purposes. It is not an experiment, but has stood and is standing the severest tests of actual use. And now that a practically inexhaustible supply of Vanadium has been discovered and is owned by this company we want everybody who uses steel, *or whose life depends upon the steel used,* to know about it.

A very interesting book on the "Discovery and Uses of Vanadium" has been prepared and will be sent free to all who ask for it

“So Near and yet so Far.”

Reach as hard as he can after the genuine Non-Fluid Oils, the imitator hasn't got any further than the label.

A name like “Non-Fluid Oil” is easily coined, but though our competitors have appropriated the idea of our name and even our name itself, they haven't got below the label—“So near and yet so far”—so *very* far! Their grease is still nothing but grease—call it by what fancy name you will.

If any grease were as good as *Non-Fluid Oil*, a big bunch of grease makers wouldn't have *had to* copy our name and pack their “dope” under such names as “Non-Flowing Oil,” “Solidified Oils,” “Non-Liquid Oils,” “Anti-Fluid,” and such like. The fact that we came first and these other things later, is certainly proof enough that we were giving the motoring public the lubricants that they wanted—*something better than grease*.

There's a mighty difference between similar *names* and similar *products*. With all the imitation to which the genuine Non-Fluid Oils is subjected, the fact still remains that there is only one real Non-Fluid Oil, and we are the original and sole makers, and that over 55 automobile makers (including the best in this country) are using and recommending *our* lubricants, and are *not* either using or recommending any of the imitations.

As you value a good car, don't leave it to the uncertain mercies of unreliable lubricants. Comfort, safety, security, pleasure and speed lie in the use of a Non-Fluid Oil. Look for our name and trade-mark on the familiar orange-enameled cans. Any good dealer will supply you.

Two Grades of Non-Fluid Oils cover all general automobile requirements.

A STRONG POINT

In Tire Equipment

☞ A point that stands out boldly in "FISK" tire construction—is the absolute impossibility of accident from tire causes.

☞ It is a "FISK" perfection—and one that cannot be dodged when selecting tire equipment—for safety from tire disaster is an important motoring comfort.

☞ No other tire product has proved 'just as good' as "The Fisk Mechanically Fastened Tires." They are locked to the rim and cannot come off from mishap, whether inflated or deflated. They cannot 'creep' or blow off, but may be removed easily and repaired with dispatch. The inner tube cannot be pinched, nor the tires torn from the rim by 'side roll.'

☞ "FISK" tires will endure every mileage service and show the least wear. They ride delightfully over smooth roads, and with gentle comfort over crude ones. At any speed—you travel safe and secure from tire calamity.

THE RELIABLE DAYTON WHICH?

Are you willing to pay 10 cents per mile for tire maintenance, not to mention the annoyance of blowouts and punctures

Do you want a 40-horsepower motor car with a proportionately heavy car and its attendant excessive fuel bill?

Are you going to buy a car to excite your neighbor's envy?

OR { Do you want to practically eliminate tire expense?

OR { Do you want a practically constructed car that will use a 15-horsepower motor with greater efficiency?

OR { for your own pleasure and for the maximum mileage at the minimum expense combined with the greatest efficiency under any conditions, favorable or unfavorable?

If questions to the right represent the kind of car you want, we will send catalog upon request.

RELIABLE DAYTON MOTOR CAR CO.,

Dept. 7.

375 W. LAKE STREET, CHICAGO, ILL.

A CAR FOR SERVICE

“Servitor”

Something New and Distinctive

in a high-powered “Gentlemen’s Roadster.” Its graceful lines and harmony of coloring make it a thing of beauty. There is nothing overlooked to make this a most desirable car for men of moderate means.

The mechanical construction is as near perfection as is possible to make it. Every pound of weight is eliminated by the use of our system of air cooling, no radiators, pumps or tanks to leak or get out of order. Get our interesting catalog giving full details.

We still have some good territory open. Great chance for reliable agent to make fine income. *WRITE for particulars.*

JEWEL argument is not a matter of superlatives nor extravagant, boastful claims. It is based upon these definite points:

There is no other gasoline car that is so easily controlled.

There is no other gasoline motor so simple.

There is no other gasoline car that costs so little for repairs and maintenance expense.

Let us give you the whole story of JEWEL construction and equipment in our free booklet. It fully describes the JEWEL Valveless, Two-cycle engine, and shows why experience, rather than advertising, has made the JEWEL famous.

**Not one
tire complaint
this year**

Thomas Flyer

Hundreds of cars in daily use for months. Some have traversed thousands of miles over roughest kind of roads. One made over 8,000 miles. Another 10,000 miles. Not one complaint of tire trouble.

Reason found in splendid policy of providing 1,500 pounds surplus tire capacity by equipping cars with larger tires and wheels at additional cost to us of over \$100. Front tires 36 x 4 inches. Rear tires 36 x 5 inches.

Proves again that we will not only eliminate all structural troubles but eliminate practically all operating troubles, such as tire troubles by use of big tough tires and ignition troubles by the use of a double ignition system.

All this is submitted for the cool and critical buyer—the conservative business man. Regardless of price no other large car can present such a grand record.

60-H. P. Thomas Flyer, \$4,000 f. o. b. factory.
40-H. P. Thomas Forty, \$2,750 f. o. b. factory.

Cadillac

MODEL G

\$2,000⁰⁰

(Lamps not included)

This is the new Cadillac which has created such a stir in the automobile world, and is the first practical demonstration that it is possible to produce a four-cylinder car at \$2,000 which, for thoroughly high-grade qualities and refinement of detail, as well as for speed and general efficiency, compares favorably with types selling at double

its price. It possesses many of the time-tried Cadillac features, and for silent, smooth running qualities it has few equals at any price. It is conservatively rated at 20 H. P. and is daily proving its superiority as a hill-climber of remarkable capabilities and demonstrating its speed at the rate of 45 to 50 miles per hour.

Material, workmanship and mechanical precision are of the kind that have made Cadillacs famous all over the world.

You cannot afford to buy a multiple-cylinder car, at any price, until you have made a demonstration in the "Model G."

Cadillac dealers can make prompt delivery.

Ask us for "Special Catalog of Model G."

NORTHERN

MOTOR CAR CO., DETROIT

Member Association Licensed Automobile Manufacturers

The real *Value* of an automobile is in proportion to its *Service* and its *Life*.

By "*Service*" we mean the ability to negotiate all roads—smooth or rough—at the right speed with a full load—the ability to travel one mile or ten thousand miles with assurance of minimum trouble and expense. By "*Life*" we mean not only durability,—resistance to wear,—but that correctness of design which survives changes of fancy—changes of style, because it is *correct*—ahead of the times.

The "Silent Northern" is pre-eminently the car of **BIG SERVICE** and **LONG LIFE**. You never see it advertised in the second-hand columns. You will know why when you know the "Silent Northern." We solicit the opportunity to send you the catalog and let it make your acquaintance.

 De Luxe Touring Model - 40 H.P.

Simple, Swift-Running, Powerful, and Correct in Mechanical Construction

1908 contracts now being made. Note the Continental's recent records in the hands of different amateurs:

- April 27th—3 mile race on half mile flat track at Branford. Time, 4:35. Regular touring equipment.
- May 7th—Regular equipment, with four persons, Continental established a record between New Haven and Saybrook, Ct., 42 miles, 1 hour, flat, and to Fenwick, Ct. 90 miles and return, in 130 minutes; 7½ gallons gasoline being consumed, officially.
- May 25th—Two races at the Yale Auto Club Meet, 3 miles on half mile track; time, 4:30; second place. Winner, a \$10,500, special De Dietrich; time, 9 seconds better.
- May 30th—Bridgeport Hill Climb, Sport Hill, second place; time, 2:12; touring car class. Free-for-all, stripped; time, 1:52; within 25 seconds of record.
- June 6th—New York Motor Club Endurance Run—200 miles to Albany—started No. 8 and finished No. 11. Clean score, absolutely no adjustment made on the road except on tires.
- June 19-22—The first car to finish with a perfect score in the Sealed Bonnet Contest, 30 minutes ahead of next car at the A. C. A. The Continental will complete 1,000 miles before seals are broken. 850 covered to date.

MODEL 67 VICTORIA PHAETON.

POPE MOTOR CAR COMPANY, Waverley Department INDIANAPOLIS, IND.

THE WINNER A Stearns

In the Cleveland Automobile Club Annual Hill Climb
on Stucky Hill, June 15th

STEARNS stock cars entered six events (all for which they were eligible) and **WON FOUR EVENTS**; were second and third in a fifth event, losing only to a special (almost a freak) racer, and beating an 80 h.p. special racer, former winner of the Vanderbilt Cup; and won third place in a sixth event, losing only to special racing cars, one of international fame.

Stearns Stock Cars beat every other stock car entered of whatever make

Only two Stearns Cars were used — one a stock 6-cylinder, the other a stock 4-cylinder. No other make of car can show such a record. The time was very fast, hill about 18% and 7-10 of a mile long. For details see the news pages.

Coming right on top of the Stearns triumphs at Wilkes-Barre, following the record-making exploits of last year, the White Mountain International Hill Climb, Gates Mills Hill Climb, and other events of national importance, you must admit the absolute superiority of the Stearns, for the proof has been given, as no one else can give it. Remember Stearns never built a racer, and these events were all won with the cars offered for your use.

Isn't it plain that the superior construction of the Stearns makes it a better car than any other for you to buy and use?

Watch for the Stearns Cars with the White Line around the radiator. See how they run. Catalogs and full descriptions free.

Immediate delivery. \$4,500, 30-60 h.p. The easy-running qualities of a "30" in highest perfection — the power of a "60" when needed. The catalog tells how. Write to-day.

Elmore
Valveless 2-Cycle

Every Valve Means Trouble and Expense

Price, Three Cylinders, \$1,750
" Four " 2,500

Why couldn't the heavy four-cycle cars win the Los Angeles fifty-mile test? Why couldn't they even equal the remarkable record of the two-cycle Elmore which won the race, averaging only 3 seconds variation per mile during the whole run?

Because the four-cycle cars were four-cycle cars; because, among other things, they had valves—and the two-cycle Elmore didn't.

Because there was loss of power in the four-cycle through intermittent application — there wasn't in the Elmore.

Because—but why more? Why not look up the everyday record of the Elmore as well as in this endurance test?

Our booklet "Our Daily Mail" will help—get it.

The Incomparable WHITE THE CAR FOR SERVICE

WHITE RELIABILITY DEMONSTRATED ON THREE CONTINENTS

In **AMERICA**, perfect scores were made by the two 30 H. P. White Steamers entered in the 600-mile Sealed Bonnet Contest of the Automobile Club of America. Both cars finished in perfect condition and were ready for several more contests of the kind.

In **EUROPE**, a 30 H. P. White Steamer recently completed an 1871-mile non-stop run from London to Glasgow, then over the route of the Scottish Reliability Contest, and back to London. This trip was made under the surveillance of an official observer appointed by the Royal Automobile Club.

In **ASIA**, White Steamers were selected by the Punjab Motor Transport Company, after severe competitive tests in which the leading makes of the world took part. Low cost of up-keep, supreme reliability, and suitability for continuous 'bus service in a mountainous country, where there are practically no repair facilities, were the factors which determined the choice. Ten White cars have just been placed in service by this company.

THOMAS B. JEFFERY & COMPANY

Packard

"THIRTY"
1908

FOR the season of 1908, the Packard Motor Car Company continues its time-tried policy of devoting its great factory to the production of motor cars of one model—a new Packard “Thirty.” In its most notable form this is a touring car, and also is furnished as a runabout, limousine and landaulet, or equipped with cape cart or Victoria top. Capable, modish in design and luxurious in appointment, the car is a Packard throughout, with improved detail and refined construction. The price of the touring car, in standard finish and equipment, is \$4,200, f. o. b. Detroit.
